between the epochs of our two surveys. Mr. Welsh's observations made in Scotland in 1857 8 fit in well with our own. Such evidence is not, however, inconsistent with minor changes, and it is certain that as the directions and magnitude of the inducing forces alter, the disturbing induced forces must alter also. But this change would be slow, and as the horizontal force is in these latitudes comparatively weak, the change in the disturbing forces would also be small, unless the vertical force altered greatly. It is at all events impossible to attribute to this cause oscillations which occupy at most eight or ten years. It is possible so suggest other changes in the state of the concealed magnetic manner—alterations of pressure, temperature, and the like—to which the oscillations of secular change might be due, but probably there will be a general consensus of opinion that if the slowly changing terms in the disturbance function are due to magnetic matter, the more rapid fluctuations of a few years' period are more likely to be connected with earth currents. It becomes, therefore, a matter of interest to disentangle the two constituents of local disturbances ; and there is one question to which I think an answer might be obtained without a greater expenditure than the importance of the investigation warrants. Are the local variations in secular change waves which move from place to place, or are they stationary fluctuations, each of which is confined to a limited area beyond which it never travels? Thus, if the annual decrease in the declination is at one time more rapid at Greenwich than at Kew, and five years afterwards more rapid at Kew than at Greenwich, has the maximum of rapidity passed in the interval through all intervening places, or has there been a dividing line of no change which has separated two districts which have perhaps been the scenes of independent variations? The answer to this question is, I take it, outside the range of our knowledge now ; but if the declination could be determined several times annually at each of a limited number of stations in the neighbourhood of London—to this inquiry, at all events—a definite answer would soon be furnished. There are two other lines of investigation which I hope will be taken up sooner or later, for one of which it is doubtful whether the United Kingdom is the best site, while the other is of uncertain issue.

If, however, it be granted that the principal cause of local and regional magnetic disturbances is the magnetisation by the earth's field of magnetic matter concealed below its surface, the question as to the nature of this material still remains to be solved. Is it virgin iron or pure magnetite, or is it merely a magnetic rock of the same nature and properties as the basalts which are found in Skye and Mull? There is, of course, no *a priori* reason why all these different materials should not be active, some in one place and some in another.

As regards the United Kingdom I have, both in a Paper on the Permeability of Magnetic Rocks and in the description of the recent survey, made calculations which tend to prove that, if we suppose that the temperature of the interior of the earth is, at a depth of twelve miles, such as to deprive matter of its magnetic properties, and if we further make the unfavourable assumption that down to that limit the susceptibility is constant, the forces which are observed on the surface are of the same order of magnitude as those which could be produced by large masses of the ordinary basalt or gabbro. It would not, however, be wise to generalise this result, and to assume that in all places regional disturbances are due to basic rocks alone.

We know that local effects are produced by iron ore, for the Swedish miners seek for iron with the aid of the magnet, and in some other cases magnetic disturbances of considerable range are so intense as to suggest that material of very high magnetic permeability must be present. If the concealed magnetic matter were iron, and if it were present in large quantity, it is evident that the results of experiments with the magnetometer and dip circle might be supplemented by observations made with the plumbline or pendulum. In such a case the region of magnetic disturbance would also be a region of abnormal gravitational attraction. An account of a suggested connection between anomalies of these two kinds occurring in the same district has lately been published by Dr. Fritsche.*

Observations made about 30 years ago by a former director of the Astronomical Observatory in Moscow led to the conclusion that throughout two large districts to the north and south of that city the plumbline is deviated in opposite directions. The deflections from the vertical are very considerable, and indicate a relative defect in the attraction exerted by the rocks in the neighbourhood of Moscow itself, and the suggestion has been made that there is either a huge cavity—a bubble in the earth-crust—under the town, or that the matter beneath it is less dense than that which underlies the surface strata on either side at a distance of 10 or 12 miles.

As long ago as 1853 Capt. Meyen made magnetic observations in order to determine whether the same district is also the seat of any magnetic irregularity. His stations were hardly sufficiently numerous to lead to decisive results, but the magnetic elements have recently been measured by Dr. Fritsche at 31 places within 50 miles of Moscow. The experiments were all made within 11 days, so that no correction for secular change is required. They indicate a locus of magnetic attraction running through Moscow itself. South of the town the disturbance again changes in direction so as to show either that repulsive forces are in play, or that there is another magnetic ridge line still further to the south. Dr. Fritsche thinks that these observations explain the gravitational anomalies without recourse to the somewhat forced hypothesis of a vast subterranean cave. He assumes that there is a concealed mass of iron which approaches near to the surface at Moscow, and also along two loci to the south and north of the city. He attributes the magnetic irregularities to the attraction of the central iron hill, the deflections of the plumbline to the flanking masses. It is, perhaps, not inconceivable that such results might follow in a special case, but without the support of calculation it certainly appears that the magnetic experiments point to the existence of the principal attracting mass under the town. This is, in fact, the arrangement shown in the figure with which Dr. Fritsche illustrates his hypothesis. If this is so, the theory would *primâ facie* seem to require that the bob of a plumbline should be attracted towards and not—as is actually the case—away from the centre of the magnetic disturbance. On the whole, then, though the coexistence of large magnetic and gravitational disturbances in the same place is suggestive, I do not think that they have as yet been proved to be different effects of the same hidden mass of magnetic matter.

In a few weeks an International Geodetic Conference will meet at Innsbruck, at which the Royal Society will be represented. It is, I believe, intended to extend the detailed investigation of the relations between the nature of the earth's crust and the gravitational and magnetic forces to which it gives rise. We may, therefore, hope that special attention will before long be given to localities where both may combine to give information as to facts outside the range of the ordinary methods of geology.

The second phenomenon on which more light is desirable is the permanent magnetisation of magnetic rocks. It is known that fragments of these are strongly but irregularly magnetised, but that the effect of very large masses at a distance appears to be due to induced rather than to permanent magnetism. There are three questions to which I should like an answer. Are underground masses of magnetite ever permanently magnetised? Are large areas of surface masses, say a few hundred square yards in extent, ever permanently and approximately uniformly magnised in the same sense? Is there any relation between the geological age and the direction of the permanent magnetism of magnetic rocks?

Inquiries such as these can only be taken up by individual workers, but I venture to think that the comparison of the observatory instruments, and the fluctuations of secular change outside the observatories, could best be investigated under the auspices of a great scientific society. The co-operation of the authorities of the observatories will no doubt be secured, but it is most important that the comparisons should in all cases be made with one set of instruments, and by the same methods. Whether the British Association, which for so long managed a magnetic observatory, may think that it could usefully inaugurate the work, it would be improper for me in a Presidential Address to forecast. Who does it is of less importance than that it should be done ; and I cannot but hope that the arguments and instances which I have to-day adduced may help to bring about not only the doing of the work, but the doing of it quickly.

* "Die magnetischen Localabweichungen bei Moskau und ihre Beziehungen zur dortigen Local-Attraction," *Bulletin de la Société Impér. des Naturalistes de Moscou*, 1894, No. IV.

Priming Tests.—In a letter to the *Engineering Record*, Prof. R. C. Carpenter, of the Sibley College, Cornell, states that in testing the quality of steam as regards priming by the calorimeter method, erroneous results will be obtained if the calorimeter supply is drawn from a horizontal pipe. Experiments made at Cornell showed that when flowing through such a horizontal pipe the steam at the bottom of the pipe contains much more water than at the top of the pipe. When the moisture exceeds 1 per cent. it collects in the form of drops on the sides of the pipe, and when more than 2 per cent. is present it can, with suitable arrangements, be seen flowing along the bottom of the pipe in a separate stream, the main body of the steam being clear and transparent, until the amount of moisture present was still further increased, when it became hazy and foggy. The best place from which to draw off steam for a calorimeter determination is from a vertical pipe, at a distance below a bend or elbow equal to about three diameters of the pipe.

The Electrician.

(The Oldest Electrical Journal, 1861—1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny

Editorial, Publishing, and Printing Offices :

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams :* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows :—

	3 months. s. d.	6 months. s. d.	12 months. s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies :—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

'THE ELECTRICIAN.' *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of*—

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS Price 12s. 6d. post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free. Also in German, 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

NOW READY.

Volume XXXII. of "THE ELECTRICIAN," price 12/6; post free, 13/6 abroad, carriage extra.

Cases for binding Volume XXXII., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

SPECIAL NOTICE.

With this week's Number of "THE ELECTRICIAN" we publish (Gratis to Subscribers) a fine STEEL-PLATE PORTRAIT of the late Dr. HEINRICH HERTZ. Complaints of non-receipt should be promptly forwarded to the Publisher.

TITLES.

Some few weeks since an esteemed engineering contemporary lifted up its voice against what it was bold enough to call the "ignoble" style of latter-day technical literature, and announced its readiness "to sacrifice some little brevity for the sake of a little more grace." In this, as in other matters, an ounce of practice is worth a pound of precept; but up to the time of going to press the increased lucidity and added grace of our contemporary's editorial columns have eluded our most careful observation. However, let that pass. The phenomenon of a staid engineering publication devoted to the interests of the "practician" vigorously pleading for a certain amount of style in engineering books is at once so unusual and so encouraging that anything approaching banter is not to be thought of. For our own part we should be content to forego style—in the strict literary sense of the word—if only we could obtain the twin blessings of clearness and conciseness in text-books, treatises, and technical papers, though we cannot go so far as a certain paradoxist who obstinately defended the position that it matters little what a man has to say so long as he makes his meaning clear, and that within the limits of the C.G.S. unit of area. Style is a most useful ancillary in the case of scientific writings intended to be understanded of the people; indeed, it is there perhaps the prime consideration; but literary gems would seem a little out of place in "An Experimental Investigation of the Circumstances under which a Change of the Velocity in the Propagation of the Ignition of an Explosive Gaseous Mixture takes place in Closed and Open Vessels." Mere brevity and lucidity would satisfy us here.

Digitized by Google

Closely allied to this question of style is the choice of suitable titles for our scientific lucubrations. A contempt for titles is generally taken as evidence of a superior mind, and it is this consideration very possibly that gives us such stupendous superscriptions as the one just quoted. It should, however, be borne in mind that "small matters win great commendation," and a title which arrests attention, indicates the purport of the Paper, and last but not least admits of easy indexing, has its value and is worth a little thought. To make a scientific discovery requires apparatus, skill, training, good luck; to make it known requires pen, paper and perspicuity; and to hand it down to posterity, after intrinsic worth, nothing avails better than a felicitous label; "in fame of learning, the flight will be slow without some feathers of ostentation."

There is fashion in titles as in all things else. In the dawn of modern physical science there was a charming directness and freshness about the titles of scientific papers. Dip for a moment into HAUKSBEE's "Physico-Mechanical Experiments," which he dedicated in 1709 to "my Lord Sommers"; "The Attrition of Glass on Oyster-Shells"; "Concerning some very uncommon effects of the Effluvia of Sealing Wax"; "An Account of an Experiment concerning the quantity of Air produced from a certain quantity of Gun Powder fired in Common Air," are the quaint and expressive finger-posts that catch the eye. The *Philosophical Transactions* for the same period exhibit almost the same characteristics in this matter of titles, though here and there one is pulled up suddenly by a strikingly modern superscription such as the "Infinitely-infinite Fractions" of a certain Dr. J. WALLIS, for which amends is promptly made by ANTHONY LEEUWENHOCK, who, in 1722, investigated the painful case of the "Magnetism acquired by Iron standing long in the same position." In October, 1748, we may remark in passing, "some gentlemen of the R. S." made many curious experiments in order to measure the absolute velocity of electricity. They stretched on dry sticks a line of iron wire of a total length of 2¼ miles 6 chains, or 12,276ft. Into this circuit they brought an "electrified phial" and "two gentlemen of the R.S.," one being at the "phial" end of the line, and the other at the earth end. On the "phial" being discharged, the other gentlemen of the R. S. endeavoured to measure the interval of time between the jump of the gentleman at the near and that of the gentleman at the distant end of the circuit. Obvious conclusion: "velocity of Electricity is instantaneous up to a distance of 12,276ft."

Coming to papers of a more recent date one might classify their titles under the headings of the picturesque, the vaguely mysterious, the dubious, the synoptical. We must confess to have had a slight *penchant* for the picturesque type of title until the danger of using "unmeaning catch words" was writ large in the columns of the *Glasgow Herald* a few days after the reading before the Physical Society of London of a Paper entitled "Electric Splashes," which interesting little discourse on Lichtenberg figures was considered across the border to "furnish powerful arguments in favour of the fluid theory of electricity." And when "Electric Splashes" were followed by "Electrical Evaporation" we straightway purged ourselves of our heretical leanings, lest we should be treated to a naval memoir dubbed "Side Lights on Search Lights." The vaguely mysterious type of title, on the other hand, possesses an undoubted advantage; it rouses curiosity. Anything, or nothing, may be wrapped up in contributions to contemporary science labelled "The Nature of Depolarisers," "A New Photometer," "A New Phenomenon," "A Sensitive Cell." The dubious style of title, however, is scarcely less effective from this point of view. "A Note on the Antecedents of Clerk-Maxwell's Electro-dynamical Wave Equations" seems to denote a grave scandal of some sort; and in "Matrices which represent Vectors" we obviously ought to have concrete representations of vectors in three dimensions, neatly moulded in plaster of Paris. Science and mathematics are at all times the bane of the typographer; but it is not until he is by way of being an artistic typographer, and encounters a sample of the synoptical variety of title that he yearns for fresh fields and pastures new. The author of one of the most interesting Papers read of late years before the Institution of Electrical Engineers endeavoured—misguided man—to sum up his investigations in his title; hence came "On the Prevention and Control of Sparking; Continuous-Current Dynamos without Winding on the Field Magnets and Constant-Pressure Dynamos without Series Winding," a portentous result only surpassed by that of a Colonel COOK, who just 150 years before read a Paper to the Royal Society, which he was good enough to christen "A Proposal for warming Rooms by the Steam of boiling Water conveyed in Pipes along the Walls: And a Method of Preventing Ships from leaking whose bottoms are eaten by the Worms."

No classification of titles, however, would be complete without a specimen—a single specimen is all our founts permit of—of the kind of title often adopted by those who "when they know within themselves they speak of that they do not well know, would nevertheless seem to others to know of that which they may not well speak," at any rate such it seems to us must be the origin of—Tetramethyldiamidotriphenoylmethane-ortho-carbonate of methyl—which afforded—well, food for thought—in a recent number of the *Comptes Rendus.*

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(Continued from page 352.)

The Performance of Boilers.

Performance during Full Load Trials.—The information which is obtained through systematic boiler trials affords data which may be of considerable use to the engineer. At the same time, there is a great deal of misplaced confidence in such information; and it is only where the conditions of trial have been carefully specified, and the trials have been conducted by an unbiassed engineer competent to carry them out, that any great reliance can be placed upon the results. We have previously remarked the discrepancy which may arise between the conditions of a careful full-load trial and the actual conditions of working, a discrepancy which is often sufficient to render the conclusions derived from the former inapplicable to the latter case. Still, in order to have exact knowledge of the suitability of any given boiler, fired with any given class of fuel, it is necessary to know what the boiler can do (1) on full load, (2) on fractional loads, (3) when forced above full load, (4) when standing-by, and (5) when being got under steam. Unfortunately, the attention of expert engineers has been much more directed to the determination of the first point than to the remaining points; and our knowledge as to these latter is as meagre as that of the former is, perhaps, too abundant. During a full-load trial the conditions of firing and steaming are kept as steady as possible, and the engineer is constantly on the alert to prevent loss of fuel or heat at any place. The results are, therefore, generally superior to those which can be obtained in practice, even where the boiler is, in practice, always maintained at full load.

Miscellaneous Boiler Trials.—As it is not necessary to enter into full particulars of trials of electric power

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

station boilers, the author has compiled the following Table of the principal results of a number of miscellaneous trials. It is to be regretted that it has been found impossible always to give results of full-load trials in actual electric power stations, in the case of these boilers; but the conditions are sufficiently similar to render the table of some value, at any rate :—

Miscellaneous Boiler Trials.

Reduced Loads.—There are no exact data of the economy of boilers when working at a given fraction of full load; and it is very important that this question should be systematically threshed out by competent engineers, by means of a series of careful trials. It is probable that there is a certain load, which ought to be the normal load, at which the evaporative efficiency is highest, and that there would be a steady fall in efficiency as this load was more and more departed from; and it is probable that this would be the case whether the departure was due to a fall below or a rise above the best load. There are certain losses in the boiler, such as those due to radiation and conduction, which may be considered to be fairly constant at all loads. Other losses, such as priming and the loss of heat up the chimney, increase rapidly as the load is raised. The loss due to the heating of diluent air in the furnace probably, in most cases, falls as the load rises, because less air is required per pound of coal where the consumption is more vigorous. Again, it is certainly more difficult, where the stoking is done by hand, to regulate the furnace economically at very low loads; and this difficulty varies with the character of the fuel. Most human stokers look after a furnace more economically with dry fuel than with smoky fuel, where the load is very low. This difficulty does not occur with mechanical stokers. The two principal elements which determine whether a furnace is doing its best, at any load, are (1) the amount of opening given to the dampers, and (2) the thickness and uniformity of the fuel on the grate. Directly a boiler is to be put on reduced load the dampers should be lowered and the fire evenly thickened, the damper being finally adjusted so as just not to give rise to smoke. If the draught is produced by a blower the force of the blower should be reduced; but the fire must be increased in thickness and the damper lowered as well, or the combustion will be uneconomical. The increase in the thickness of fuel on the grate, and the amount of lowering of the dampers, must vary directly with the fall in the steaming rate of the boiler.

Absolute Efficiency of Steam Generators.—The steam boiler has the credit of being considered by engineers to be a very efficient appliance; but it requires only a little investigation on scientific lines to reveal the fact that this credit is entirely misplaced, and that the steam boiler is a most inefficient and wasteful adjunct to power plant. Indeed, a very large proportion of the loss in steam plant takes place in the boiler or, to be more correct, between the boiler and the furnace. The praise which has been lavished upon boilers has taken its authority in the large percentage of the heat of the fuel which is imparted to the steam raised by that fuel. We may rightly assume that a good boiler, working at full load, will raise 10lb. of steam for every pound of good coal burned on the grate; the feed water being supplied to the heaters at 60°F. and evaporated at 200lb. pressure (388°F.), and the total thermal value of 1lb. of the coal being assumed to be 14,500 B.T.U. On this basis, we see that as much as 11,720 B.T.U. is imparted to the 10lb. of feed water in generating the steam; a figure which represents about 80 per cent. of the total heat of the fuel. Only 20 per cent., or 2,780 B.T.U., is wasted in radiation and other losses, and in developing the draught. Accordingly, it has been said that the thermal efficiency of a good boiler may be as high as 80 per cent. !

The argument is specious, but utterly wrong. Of what use is it that the boiler should turn out 80 per cent. of the total heat of the fuel, when it turns it out in such a form that only a very small fraction of this percentage can possibly be utilised for doing work? The mere fact that 80 per cent. of the heat passes through the heating surfaces into the water, and passes with the steam along the pipes to the engine, is not an adequate performance. In order to have a true efficiency of this value the boiler should serve up the heat in such a form that 80 per cent. of the total heat is really available for doing work in an engine. Let us see what the real efficiency of a steam generator amounts to.

We have said that, of the 14,500 B.T.U. in one pound of coal, some 11,720 enters the steam. Now, the temperature of the steam (at 200lb.) is 388°F.; and the thermal energy of the steam is only available from this temperature down to (say) 60°F. Therefore, the total available heat in 10lb. of steam is, by equation (67),

$$11{,}720 \times \left(\frac{388-60}{388+460}\right) = 4{,}524 \text{ B.T.U.}$$

But 4,524 B.T.U. is only 31 per cent. of the total heat of combustion of the pound of coal. Instead of 80 per cent., therefore, only 31 per cent. of the heat is available from the coal, when we employ a steam boiler to utilise it. It is interesting to note that 4,524 B.T.U. is the total heat of combustion of about five ounces of good coal.

We may localise the source of this tremendous loss of efficiency, a loss amounting to 69 per cent. In the furnace there may be a temperature of some 3,000°F., in the boiler the temperature is but 388°F.; consequently, about 12,324 B.T.U., or 85 per cent., is available in the furnace, whereas only 4,524 B.T.U., or 31 per cent., is available in the boiler. The passage of the heat through the fraction of an inch which represents the thickness of the useful heating surface is sufficient to cause a drop in the efficiency from 85 down to 31 per cent.!

We ask: How shall this unhappy state of affairs be remedied; how shall we obtain a steam generator which will yield us a very much higher percentage of heat in an available form? Since it is improbable that we can improve the efficiency of a good boiler by the process of getting more heat into the steam—because there is already as much imparted to the steam as we may expect to impart—the only way to raise the efficiency is to develop the *availability* of the heat, *i.e.*, to generate the steam at a higher temperature. To do this, we must either develop a much higher steam pressure, or else we must superheat the steam with the furnace heat. Both these methods are open to practical objection, so that probably we must be content with an efficiency never exceeding, and often very far inferior to, 31 per cent.

Some writers have attributed the great inefficiency of steam plant to the engine, not to the boiler. That the boiler and not the engine is principally the culprit is evident from the fact that if we wish to cause a considerable rise of efficiency, we must improve the boiler; there is not so much need to improve the engine.

As we shall presently see, the engine in steam plant is by no means as perfect as it might be made; but, at the same

* The fuel was mechanically stoked with Vicars' stokers. This trial was conducted at Warrington, by Dr. Markel.

† Vicars' stokers were used. This trial was conducted at Falcon Wharf hydraulic-power station, by Mr. E. B. Ellington, M.I.C.E.

Digitized by Google

time, any radical improvement in the thermodynamic efficiency of the whole plant can only be made by means of radical improvements in the boiler and furnace.

It must not be forgotten that boiler plant is usually far from evaporating 10lb. of water for every 14,500 B.T.U. developed in the furnace; also that steam is often raised at lower temperatures than 388°F. Consequently, when the average performance throughout a day or a year is considered, the thermal efficiency of steam raising is always below 31 per cent.—sometimes as low as 5 per cent. At this last figure, the available units of heat amount to 72·5 B.T.U. per pound of coal; which is approximately the heat of combustion of one-twelfth of an ounce of good coal. Hence, although there is little hope of improving the present best, there is plenty of room for possible improvement in the present average performance of boilers. It is in this fact that the hope of higher economy in steam-driven electric power stations must chiefly rest. There is, as Prof. Kennedy has pointed out, far more difference between the present best and the present average performance, than there is between the present best and the best possible. In a lesser degree, these remarks apply also to the engines.

(To be continued.)

ON IMPULSIVE CURRENT-RUSHES IN INDUCTIVE CIRCUITS.

BY ALFRED HAY, B.SC. (EDIN.).

(Concluded from page 394.)

§ 21. From the experiments described in the preceding paragraphs it will be seen that the phenomenon of impulsive current-rushes is a very frequent and general one, and that the cases in which there is no distortion of the initial current-waves are the exception rather than the rule. In circuits of constant permeability these current-rushes never reach any very high value, the greatest value of the abnormal current being always less than twice the maximum value of the normal current. In the case of circuits containing iron, on the other hand, we may have enormous rushes; even when the iron is worked at a very low magnetic induction, the maximum value not exceeding 500 C.G.S. lines per sq. cm., the current rush is much greater than could occur in a circuit of constant permeability. As the normal maximum of magnetic induction increases, the current-rush increases very rapidly, so that with the older types of transformers, in which the normal maximum frequently exceeded 6,000 C.G.S. lines per sq. cm., we should expect some very extraordinary rushes. With *very low* degrees of magnetic induction, the initial state of the iron does not very seriously affect the current-rush. But with moderately high degrees (say, from 2,000 C.G.S. lines per sq. cm. upwards), such as are used in transformers of modern construction, the initial state of the iron very materially influences the amount of the "rush."

§ 22. With regard to the effect of varying the periodicity, it has been stated by some experimenters that current-rushes do not occur at high periodicities. The periodicity used in the experiments described above was rather high—122 ∿ per second—and we see that very large current-rushes may occur at this periodicity. It has also been pointed out in § 11 that in the case of circuits of constant permeability, a change of periodicity, so far as it has any appreciable effect at all, tends to *increase* the current-rush. *Statistical* experiments have been described which seem to show that *under ordinary conditions, with a more or less slow-acting switch*, current-rushes may be to a large extent reduced by increasing the periodicity. In the writer's opinion, this effect is due, not to a change in the periodicity directly, but to the simple fact that, with an ordinary switch, the point of making contact becomes more and more indefinite as the periodicity increases; and, unless contact is made at a definite point of the E.M.F. wave, no large current-rush need be expected.

§ 23. We shall now give a description of the special switching arrangement by means of which the results described above have been obtained. As already mentioned, the alternator used was one of the old Ferranti pattern, with two driving pulleys, one at each end of the armature spindle. One of these pulleys was removed, and the length of spindle exposed was sufficient for carrying the switching and contact-making apparatus. A diagram of the connections of the switching apparatus is given in Fig. 13. G S is a graduated scale, which is insulated and supported by wrought-iron standards attached to the frame of the alternator. This scale carries two sliders, S and S_1, to which are attached the brushes B and B_1; each slider is provided with a terminal and a clamping-screw. The actual arrangement used is shown in Figs. 14 and 15 (where all unnecessary detail is omitted, so as to show

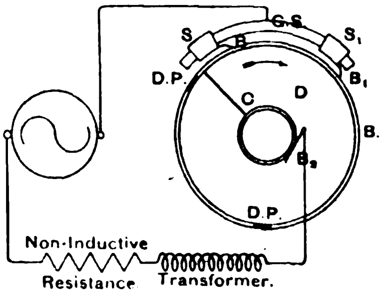

FIG. 13.

the essential parts more clearly). A wooden disc, D, is keyed to the alternator spindle, and is provided with a brass rim, B R, which consists of two unequal portions separated from each other by distance-pieces, D P (Fig. 13) of vulcanite. The larger portion of the rim is the active one, the other being attached merely for the sake of true running. A small cylinder of hard wood carries the collar, C, which is in metallic connection with the active portion of the brass rim, B R of the disc. A brush, B_2, bears on this collar; the remainder of the connections are easily made out from the diagram, Fig. 13. It will at once be seen that when one or both of the brushes B and B_1 bear on the active portion of the rim, the circuit is

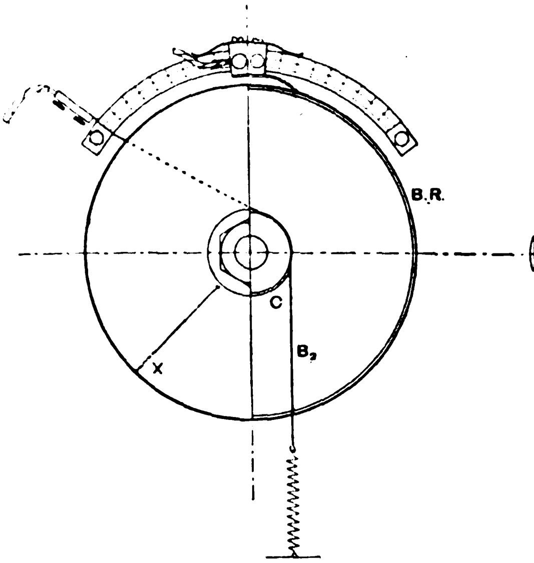

FIG. 14.

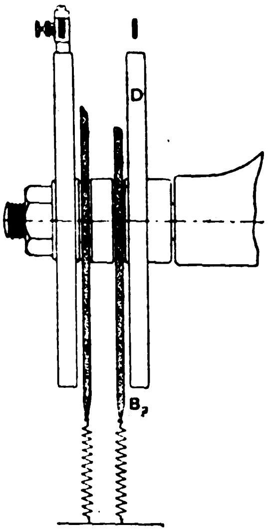

FIG. 15.

completed; but if both of them rest on the dummy portion the circuit is open. Again, as the disc revolves, the brush B is the first to *make* contact, so that by sliding B along the scale the instant at which the circuit is closed may be varied; the brush, B_1, on the other hand, is the last to *break* contact, and by sliding it along the scale the switching-off point may be controlled independently. The brushes marked B and B_1 consisted of several thicknesses of copper foil, while the brush marked B_2 was in the form of a long braided conductor of fine copper wires, which passed round the collar C, and was kept taut by means of a fine spiral spring. This is shown clearly in Figs. 14 and 15. Of the two discs there shown, the inner one is the switching disc; while the outer one, which has no

metallic rim, but merely a thin strip of brass, X (Fig. 14), let into it radially and connected to a collar, acts (after the manner first used by Joubert) as an instantaneous contact-maker, and may be used for obtaining the shape of the E.M.F. and current curves, in accordance with the method described in § 2.

When the switching disc is in action, the current is switched on and off cnce in every revolution. Hence, if there are any abnormal waves of current, they will be reproduced once in every revolution of the disc. A state of forced vibration is thus kept up, the abnormal waves being periodically started and arrested. These abnormal waves can, however, be only allowed to run through a limited number of periods—the greatest number possible with the arrangement of apparatus described being about 6½ periods. The number of periods during which the current may be kept on obviously depends on the number of poles in the alternator.

The switching arrangement just described may be applied to the study of the abnormal waves which make their appearance in inductive circuits possessing capacity as well as self-induction. It is the writer's intention so to use the arrangement, and to supplement the experiments described in these articles by others in which the iron is pushed to a much higher magnetic induction; also, to investigate the effect of varying the periodicity. In the meantime, the above sketch of the apparatus used and results obtained must suffice.

In concluding the present series of articles, I desire to express my obligations to Professors Robinson and Heaton for encouragement in the work, and every facility afforded for carrying out the experiments.

PREPARATION OF SOLUTION FOR ACCUMULATORS.

BY H. M. SAYERS.

In erecting a battery of accumulators abroad the writer had to face the question of preparing the electrolyte on the spot, as shipping it was impracticable. There are obviously some difficulties in making a large quantity of acid solution, and distributing it to the cells; and as it is injurious to the plates to be in the acid for more than a very few hours before charging is commenced, it is necessary to make the whole quantity needed and have means of distributing it at once. In this case about 600 gallons of solution of a density of 1215 was needed.

Slate, being cheap in the neighbourhood, was selected for the mixing-tank, which was made of sufficient size to contain about 25 per cent. excess of liquid. It was made in the usual way, the bottom being grooved to receive the four slabs forming the walls, and the two longer of these slabs being grooved to receive the ends of the others, the whole held together by iron bolts and nuts passing through the overlapping ends of the two longer walls. As the tank was put together the grooves were all painted thickly with anti-sulphuric enamel, and caulked with red lead putty inside and out. The whole innner surface was then painted with two coats of anti-sulphuric enamel and received two pretty thick coats of asphalte, as used for waterproofing walls, put on hot, the angles being all rounded. The tank has given no trouble by leaking. The discharge cock is of ebonite, and put in 6in. above the tank bottom to avoid taking off any sediment. The tank stands on a strong wooden framing, sufficiently raised from the floor of the battery room for the acid to flow by gravitation into the cells, with the tank nearly empty to the cock level. The solution was distributed to the cells by means of a strong rubber hose and some ebonite tubing of 1¼in. diameter, and a bib-cock on the end of the hose. Filling 60 cells with 10 gallons each of fluid took about six hours, and there was an entire absence of slopping on the floor, connections, &c.

The tank had about 4·096 cubic metres, or 144·77 cubic feet capacity, being 1·60m. (5ft. 3in.) cube inside. Taking the mean of two or three tables, acid of 1215 specific gravity at 15°C. has 29·6 per cent. of monohydric sulphuric acid, this last having 1842 specific gravity at the same temperature. Calculations gave the result that on this basis the tank should be filled to a height of 1·27m. (3ft. 11⅛in.) with water, to which should be added 1,367 kilos (3,007lb.) of the strong acid, which should give about 3·810 cubic metres of solution. The 600 gallons for the cells being equal to 2·73 cubic metres, the difference made up the space from the bottom to the tap level, and 20 per cent. extra for stock.

The acid used was from the St. Gobain works in France, and was purchased on the spot. As railway and steamship people impose troublesome regulations about transport of acid, which make the freight for small quantities very expensive, it was not practicable to order it specially. The acid marked 1,840 special gravity was of very good colour, and fairly pure. As it was slightly under the 1842 of monohydric acid about 1,375 kilos. were used. The special gravity of the resultant solution at 15°C. was very exactly 1215.

The tank was filled with water to the calculated height, and the carboys emptied into it one at a time, slowly and at intervals. Two days were allowed for this mixing, half the acid being put in each day, to avoid excessive heating. The temperature was checked by a thermometer, and thus never rose above 40°C. The tank took three days to cool down to the air temperature. A test of the solution showed that it contained a distinct amount of metals of the "arsenic and copper groups," mostly arsenic apparently, but no detailed analysis was made. Iron was also present, but is not considered prejudicial to cells as far as the writer knows. It was thought advisable to get rid of the arsenic, &c. To precipitate these metals by the passage of sulphuretted hydrogen would have been a most annoying and troublesome process, and seemed impracticable for various tolerably obvious reasons.

The following plan was thought of and carried out. Sulphuretted hydrogen was prepared in the ordinary way in a hydrogen generator as used for lead-burning, connected to a small gasholder, to allow of regulation of pressure of the gas. This hydrogen generator and gasholder had served for the lead-burning needed in erecting the battery, and were therefore at hand. From the gasholder a branch was connected on to a lead tube soldered into the centre of a sheet of lead a foot square, with the edges turned downwards. This was immersed in a lead battery box, the corners of the lead tray or sheet being supported an inch or so above the bottom of the box. The box was filled up with a strong solution of caustic soda, about 22lb. in about five gallons of water. The tray obliged the gas to pass over a large surface of the soda solution before it had a chance of escaping upwards. The pressure on the gasholder was then adjusted until only a very occasional bubble escaped from under the tray, thus ensuring as nearly as possible a complete absorption of the gas by the soda. As a matter of fact, very little gas escaped, and no serious annoyance was caused in the building. A solution of a sulphide of soda was thus prepared, and this was added in small doses to the sulphuric acid solution, a funnel with a leaden pipe reaching to the tank's bottom being used, to ensure a complete action on the whole body of liquid. Each addition of this solution produced a most violent agitation in the acid liquid, and promoted its complete mixture better than hours of paddling would have done, though a paddle was also used during the two days of mixing. The liquid was very turbid after this treatment, but settled in the course of three or four days, the sulphides precipitated falling below the cock level of course. The clear liquid gave no precipitate with sulphuretted hydrogen, showing its freedom from the objectionable metals. About 30lb. of crystallised sulphate of soda was added to the solution afterwards.

It may be claimed for the use of the sulphide of soda that it purifies the acid with a mere fraction of the inconvenience resulting from the use of hydrogen sulphide, especially when it can be bought ready made; that it is very cheap, much cheaper than sulphide of barium, which has also been used for the purpose; that it introduces no useless or prejudicial substance into the solution, but that the sulphate of soda resulting is well known to be beneficial to the cells; and that it robs the solution of no acid as the barium sulphide does.

The battery for which this solution was made has been in use over a year, giving very good results, partly due, certainly, to the absence of objectionable metal in the electrolyte.

Digitized by Google

The purple or permanganate-like colouration during charging is very pronounced in these cells. It seems to the writer to be produced solely at the positive plates, which it envelopes like a thick skin during the middle part of the charging time, slowly diffusing with the circulation of the acid at the sides and ends of the cell, but always keeping away from the negative plates. It would, therefore, seem to be a result of oxidation, probably of iron present in the solution. Possibly the presence of sodium may assist in its production; but, as the writer has not investigated the matter, these are only guesses, of little value except for basing experiments on.

It may be added that the preparation of these four tons of strong acid solution was carried out without material damage to person or property, the worst accident happening to a man who kicked over an opened carboy, and fell on top of it. His nether garments were a sad sight afterwards. A large quantity of whitening was kept at hand for the purpose of soaking up any acid spilt. This is better than soda, ammonia, or sawdust, because it is very cheap, and both neutralises the acid, and remains in a solid state easily removed and inoffensive. It should be kept in every battery room. A bottle of ammonia for application to clothes and skin in case of need is an obvious precaution; but for acid on the face or other tender part plentiful cold water at once, and oiled rags afterwards if the skin is destroyed are the best remedies. The writer once got strong sulphuric acid in one eye, but immediate and forcible application of cold water prevented permanent damage.

OBSERVATIONS ON THE GRADIENT OF ATMOSPHERIC POTENTIAL AND ON THE RADIATION OF ULTRA-VIOLET LIGHT FROM THE SUN.*

BY JULIUS ELSTER AND HANS GEITEL.

It has been conjectured by von Bezold and Arrhenius that the phenomena of atmospheric electricity are directly connected with solar radiation. The discovery by the authors of the photo-electric action produced on various substances by the most refrangible rays of sunlight (called *ultra-violet* for the sake of brevity), appeared to confirm this view, and led them to investigate the matter experimentally. After constructing a photometer based upon the discharge of electricity by light, they commenced in Wolfenbüttel a series of observations of ultra-violet radiation from the sun on clear days, which extended from September, 1889, to October, 1891. Some of the observations (July, 1890) were made at the Sonnblick Observatory, or its low-level station of Kolm-Saigurn. Along with these measurements they determined by Exner's method the intensity of the earth's electric field at hourly intervals when the weather permitted. The first section of this Paper treats of the measurements of atmospheric electricity, the second of the construction and trial of the photometric apparatus; in the third section the electric and photometric observations are compared, and the fourth part deals with the absorption of ultra-violet light by the atmosphere.

The gradient of atmospheric potential was determined in absolute measure as follows: A beam protruding from a window supported a burning petroleum lamp at any one of five measured distances from the wall. The lamp was connected to the leaves of a calibrated Exner electroscope, and served to equalise the potentials of the air and the leaves; the outer case of the electroscope was put to earth by connecting to a gas-pipe. Readings were taken at each distance, and a correction was made for the disturbance produced by the wall of the house; all observations were reduced, so as to give the potential difference between the earth and a point in free space 100cm. above its surface. The atmospheric potential was found to be greatly disturbed during the formation of clouds or rain; the observations made within the two hours preceding such formation were therefore rejected. On the other hand, isolated cirrus clouds, and such as were not being precipitated, gave rise to no appreciable disturbances. On very windy days it was impossible to keep the lamp alight, and observations were suspended; but with a moderate wind the readings taken at still moments agreed among themselves.

The results are discussed from two points of view—(1) with reference to the values of the potential gradient at different times of the day or year, (2) with regard to the relation between potential gradient and humidity of the air. The highest monthly average of potential gradient occurs in December, its value being 470 volts per metre; it falls more or less continuously to 102 volts per metre in June, and then rises again until December (*see* Fig. 3, electrometer readings). With the exception of three extremely cold days in December, 1890, the air was always found to be positively charged, the negative charge on these days being possibly due to the friction of frozen snow particles blown over the ice surface of the earth by a strong S.E. wind. The hourly observations during the winter months November—March showed the potential gradient to be higher in the evening than in the morning, reaching a maximum generally about 9 or 10 p.m.; the curves for these months are, however, very irregular. In the summer months much greater regularity prevails, a high value in the forenoon decreasing to a low minimum at sunset, or (in the case of June and July) a few hours before sunset.

* Abstracted from *Wied. Ann.*, XLVIII. (1893), pp. 338-373. By Dr. James L. Howard.

In comparing potential gradient and humidity, the records of the meteorological station at Brunswick were made use of to furnish the values of the latter. According to a theory of Exner the relation of potential-gradient, P, to humidity, q, is given by $P = A/(1 + \kappa q)$, where κ and A are constants, and q is measured as the number of grammes of moisture in a cubic metre of air at the earth's surface. As long as q is less than 8·0, the results confirm Exner's theory, but for greater values they differ entirely from it.

In order to determine the intensity of the ultra-violet solar radiation an actinometer was constructed, the action of which depends on the photo-electric properties of these rays. A surface of chemically-pure amalgamated zinc connected to a negatively-charged electroscope was exposed to the sun's rays and the rate of disappearance of the charge was noted. It was found that a fresh amalgamation, followed by rubbing with dry tissue paper, served to almost completely restore the surface after exposure to light. By this device a surface having always the same composition and degree of polish was obtained, thus enabling the observations of different days to be compared. Preliminary experiments were undertaken to determine the relation between the intensity of illumination of the plate and the rate of disappearance of its charge. For this purpose a constant source of ultra-violet light was required, and was furnished by the sparks of a 2-cm. spark induction coil, the secondary terminals of which were placed about 1mm. apart and connected to the coatings of a Leyden jar. On completing the primary circuit short bright sparks appeared between the terminals of the coil and continued with great regularity until the circuit was again broken. Exposure of the zinc plate to light was effected by placing it in front of the terminals, and the time of exposure was reckoned from the instant of making the primary current to that of breaking it. The exposure box is shown in Fig. 1.

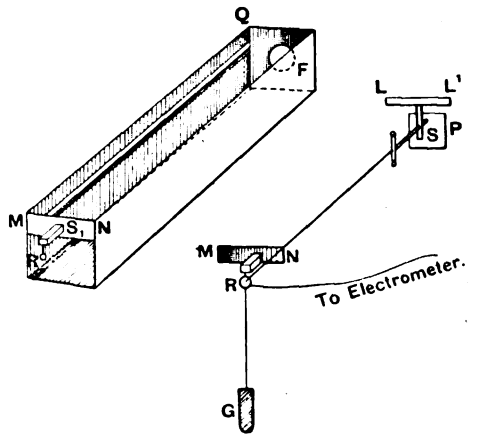

Fig. 1.—Experimental Ultra-Violet Actinometer.

The plate P is carried by a rod of sealing-wax S, which is fastened at right angles to a wooden cross-piece L L'. A wooden box about 100cm. long and 100sq. cm. in section (nearly square) is provided with a removable lid, and one of its smaller sides contains a circular window, F, about 2·5cm. in diameter, and glazed with transparent selenite. The opposite face is completely cut away with the exception of the narrow strip M N, on the outside of which a metallic ring R is fastened by means of a rod of sealing-wax S_1. The rod L L' can be slid along the box, and is supported by two projecting strips, one of which, M Q, is seen in the figure; P then swings freely without touching the sides of the box. A thin wire attached to P passes through the ring R to a small weight, G, which keeps it stretched. The connection to the electrometer is made at R. The electrometer used was an aluminium-leaf electroscope, provided with a graduated scale, and calibrated by charging from a battery of many cells. In order to screen the plate P and the electrometer from the direct electrostatic action of the induction-coil, a sheet of tin-plate about 21cm. in diameter, with a hole at its centre covered by fine iron-wire gauze, was inserted between the selenite window F and the terminals of the coil.

Digitized by Google

The result of the preliminary experiments confirmed an assumption made by the authors that the change in the rate of discharge produced by light is proportional to the intensity of the light; the rate of discharge being taken as the ratio of the loss of charge per second to the original charge. The initial potential of the plate was usually about 230 volts, and the time of exposure to light amounted in some cases to two minutes.

With sunlight the much greater intensity of illumination would have necessitated an extremely short exposure of the plate. To avoid this, the electrical capacity of the electrometer and the exposed surface were increased by the addition of a small condenser, and the movable plate P was replaced by a fixed small amalgamated zinc knob. Two such actinometers were constructed of similar design; the knob of one was left exposed to radiation from all parts of the sky, and thus measured the total ultra-violet illumination falling upon any point, while the other had its knob surrounded by a tube which could be directed to receive the radiation sent directly from the sun. The latter form is depicted in Fig. 2.

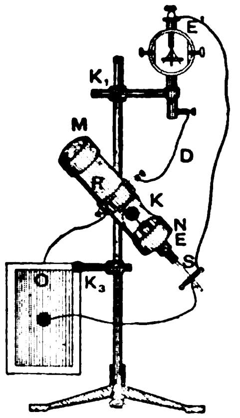

Fig. 2.—Solar Ultra-Violet Actinometer.

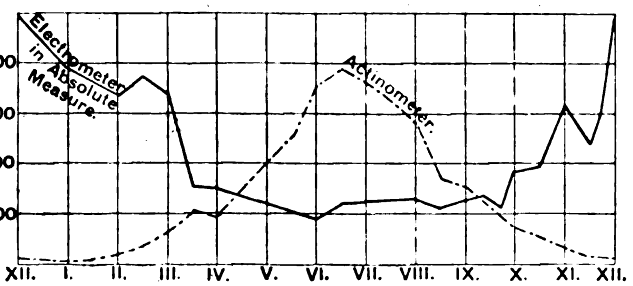
The apparatus consists of an upright rod carrying three clamp supports, K_1, K_2, K_3, by which the electrometer, exposure-tube, and condenser are respectively supported. One coating of the condenser, the exposure-tube, and the case of the electrometer are all connected together and earthed; the leaves of the electrometer, the knob K (insulated by ebonite at E), and the other coating of the condenser form the charged system. A charge is imparted by connecting to a dry-pile, and exposure is effected by taking off a cap which covers the end M of the exposure-tube.

The intensity of the ultra-violet radiation from sun and sky, as measured at noon, increases from a minimum in December to a maximum about 60 to 80 times as great during the latter half of June (see Fig. 3, dotted line); the value then falls again to the minimum in December. The curve is not symmetrical, the actinometer (at Wolfenbüttel) receiving more illumination from June to December than from December to June. This points to a sort of lag in the transparency of the air, analogous to that observed in connection with air-temperature and solar declination. The hourly observations show the same lag, afternoon readings being much greater than those taken at the corresponding time before noon; this phenomenon has been noticed in the case of the chemical rays also by M. Marchand at Fécamp. In March, April, September, and October the maximum intensity of ultra-violet radiation occurs before noon, and in March and April the curves show a well-defined depression at noon. Calorimetric and bolometric measurements have previously indicated a diminution in the sun's radiation at the time of its culmination (Crova and Houdaille, *Ann. de Chim. et Phys.*, 1890, p. 88).



Simultaneous Actinometer and Electrometer Observations. (Yearly Curves.)

Fig. 3.—Annual Variations of Atmospheric Potential-Gradient and of Ultra-violet Solar Radiation (dotted line). The abscissæ denote months of the year.

From the values of the atmospheric potential-gradient (P) and those of intensity of ultra-violet radiation (I) measured at the same time, the authors seek to establish an empiric formula connecting the two phenomena. The observations are fairly consistent with the relation $P = P_0 / (1 + \kappa I)$ where P_0 and κ are constants. A less satisfactory agreement is obtained when I is taken as the total diurnal illumination instead of the illumination at any particular moment. It is shown that if during the day the earth's surface discharges electricity into the layers of atmosphere vertically above it at a rate proportional to the intensity of its illumination, and if the night be long enough for the restoration of electric equilibrium, then the formula given above ought to hold good, taking I as the total diurnal illumination. Exact agreement of theory and experiment is hardly to be expected, since the rays which cause the earth's surface to lose its charge may not be the same as those which affect the zinc plate, *e.g.*, long waves may be effective in the case of the earth's charge. If such an electric convection be assumed its electro-magnetic effect would account for the diurnal variations of the magnetic elements; it has been shown by Schuster (*Phil. Trans.*, Vol. 80 (1889), p. 467), that these variations can be explained by the existence of electric currents in the atmosphere, the intensity of which depends on the sun's position.

During the experiments it was observed that the ultra-violet radiation was generally greater or less according as the air contained more or less moisture. As moist air is generally supposed to absorb ultra-violet light this seemed somewhat paradoxical. Experiment showed that the increased rate of discharge was not due to bad insulation, variation of temperature, or change in sensitiveness of the zinc surface; moreover, a similar observation has been made by Roscoe in the case of chemically active rays of sunlight. The authors consider that the presence of fine dust in the air is the cause of decrease in its transparency; on moist days, if dust is present, clouds form, and so prevent observation; but if the sky be clear and the air moist, the amount of dust must be very small, and consequently the air very transparent.

The concluding section of the Paper treats of the absorption of ultra-violet light by the earth's atmosphere. The intensity of the ultra-violet radiation received directly from the sun was measured for different values of the sun's altitude; from the measurements of each day the transparency of the air and the intensity of the radiation at its entrance into the earth's atmosphere were calculated. Experiments were made at Wolfenbüttel, Kolm-Saigurn, and at the summit of the Sonnblick. The results indicate a large amount of absorption in the upper and lower regions of the atmosphere, and a much greater transparency at intermediate heights. The authors explain this by supposing that nearly all the waves which the air can absorb are sifted out in the upper atmosphere, the rest passing on without much absorption. On reaching the lowest layers dust is encountered, and the intensity is diminished because of its presence. Similar irregularities in the absorption of solar radiation throughout the whole spectrum have been previously observed by Langley at Mount Whitneyins, and by Crova and Houdaille at Mont Ventoux.

BRITISH ASSOCIATION AT OXFORD.

LORD SALISBURY'S PRESIDENTIAL ADDRESS.

As Chancellor of the University it is my duty to tender to the British Association a hearty welcome, which it is my duty as President of the Association to accept. In presence of the high priests of science I am only a layman, and all the skill of all the chemists the Association contains will not transmute a layman into any more precious kind of metal. Yet it is my hard destiny to have to address on scientific matters probably the most competent scientific audience in the world. I bespeak some spark of the divine emotion of compassion in my attempt to discharge this duty.

The relations of the Association and the University are those of entire sympathy and goodwill, as becomes common workers in the sacred cause of diffusing enlightenment and knowledge. But we must admit that it was not always so. A curious record of a very different state of feeling came to light last year in the interesting biography of Dr. Pusey, which is the posthumous work of Canon Liddon. In it is related the first visit of the Association to Oxford in 1832. Mr. Keble, at that time a leader of University thought, writes indignantly to his friend to complain that the honorary degree of D.C.L. had been bestowed upon some of the most distinguished members of the Association. "The Oxford doctors," he says, "have truckled sadly to the spirit of the times in receiving the hodge-podge of philosophers as they did." It is amusing, at this distance of time, to note the names of the hodge-podge of philosophers whose academical distinctions so sorely vexed Mr. Keble's gentle spirit. They were Brown, Brewster, Faraday, and Dalton. When we recollect the lovable and serene character of Keble's nature, and that he was at that particular date probably the man in the University who had the greatest power over other men's minds, we can measure the distance we have traversed since that time, and the rapidity with which the converging paths of these two intellectual luminaries—the University and the Association—have approximated to each other. This sally of Mr. Keble's was no passing or accidental caprice. It represented a deep-seated sentiment in this place of learning, which had its origin in historic causes, and which has only died out in our time. One potent cause of it was that both bodies were teachers of science, but did not then in any degree attach the same meaning to that word. Science, with the University, for many generations bore a signification different from that which belongs to it in this assembly. It represented the knowledge which alone in the Middle Ages was thought worthy of the name of science. It was the knowledge gained not by external observation, but by mere reflection. The student's microscope was turned inward upon the recesses of his own brain; and when the supply of facts and realities failed, as it very speedily did, the scientific imagination was not wanting to furnish to successive generations an interminable series of conflicting speculations. That science—science in our academical sense—had its day of rapid growth, of boundless aspiration, of enthusiastic votaries. It fascinated the rising intellect of the time, and it is said—people were not particular about figures in those days—that its attractions were at one time potent enough to gather round the University 30,000 students, who, for the sake of learning its teaching, were willing to endure a life of the severest hardship. Such a state of feeling is now an archæological curiosity. The revolt against Aristotle is now some three centuries old. But the mental sciences which were supposed to rest upon his writings have retained some of their ascendency even till this day, and have only slowly and jealously admitted the rivalry of the growing sciences of observation. The subject is interesting to us, as this undecided state of feeling coloured the experiences of this Association at its last Oxford visit, nearly a generation later, in 1860. The warmth of the encounters which then took place has left a vivid impression on the minds of those who are old enough to have witnessed them. That much energy was on that occasion converted into heat may, I think, be inferred from the mutual distance which the two bodies have since maintained. Whereas the visit of 1832 was succeeded by another visit in 15 years, and the visit of 1847 was succeeded by another visit in 13 years, the year 1860 was followed by a long and dreary interval of separation, which has only now, after four-and-thirty years, been terminated. It has required the lapse of a generation to draw the curtain of oblivion over those animated scenes. It was popularly supposed that deep divergencies upon questions of religion were the motive force of those high controversies. To some extent that impression was correct. But men do not always discern the motives which are really urging them, and I suspect that in many cases religious apprehensions only masked the resentment of the older learning at the appearance and claims of its younger rival. In any case, there is something worthy of note, and something that conveys encouragement, in the difference of the feeling which prevails now and the feeling that was indicated then. The old learning no longer contests the share in education which is claimed by the new, or is blind to the supreme influence which natural knowledge is exercising in moulding the human mind.

A study of the addresses of my learned predecessors in this office shows me that the main duty which it falls to a President to perform in his introductory address is to remind you of the salient points in the annals of science since last the Association visited the town in which he is speaking. It will be more suitable to my capacity if I devote the few observations I have to make to a survey, not of our science, but of our ignorance. We live in a small, bright oasis of knowledge, surrounded on all sides by a vast, unexplored region of impenetrable mystery. From age to age the strenuous labour of successive generations wins a small strip from the desert and pushes forward the boundary of knowledge. Of such triumphs we are justly proud. It is a less attractive task—but yet it has its fascination as well as its uses—to turn our eyes to the undiscovered country which still remains to be won, to some of the stupendous problems of natural study which still defy our investigation. Instead, therefore, of recounting to you what has been done or trying to forecast the discoveries of the future, I would rather draw your attention to the condition in which we stand towards three or four of the most important physical questions which it has been the effort of the last century to solve.

Of the scientific enigmas which still, at the end of the nineteenth century, defy solution, the nature and origin of what are called the elements is the most notable. It is not, perhaps, easy to give a precise logical reason for the feeling that the existence of our 65 elements is a strange anomaly, and conceals some much simpler state of facts. But the conviction is irresistible. We cannot conceive, on any possible doctrine of cosmogony, how these 65 elements came into existence. A third of them form the substance of this planet. Another third are useful, but somewhat rare. The remaining third are curiosities scattered haphazard, but very scantily, over the globe, with no other apparent function but to provide occupation for the collector and the chemist. Some of them are so like each other that only a chemist can tell them apart; others differ immeasurably from each other in every conceivable particular. In cohesion, in weight, in conductivity, in melting point, in chemical proclivities they vary in every degree. They seem to have as much relation to each other as the pebbles on a sea beach, or the contents of an ancient lumber room. Whether you believe that creation was the work of design or of inconscient law, it is equally difficult to imagine how this random collection of dissimilar materials came together. Many have been the attempts to solve this enigma; but up till now they have left it more impenetrable than before. A conviction that here was something to discover lay beneath the persistent belief in the possibility of the transmutation of other metals into gold, which brought the alchemy of the Middle Ages into being. When the immortal discovery of Dalton established that the atoms of each of these currents have a special weight of their own, and that, consequently, they combine in fixed ponderable proportions, from which they never depart, it renewed the hope that some common origin of the elements was in sight. The theory was advanced that all these weights were multiples of the weight of hydrogen—in other words, that each elementary atom was only a greater or a smaller number of hydrogen atoms compacted by some strange machinery into one. The most elaborate analyses, conducted by chemists of the highest eminence—conspicuously by the illustrious Stas—were directed to the question whether there was any trace in fact of the theoretic idea that the atoms of each element consist of so many atoms, or even of so many half-atoms, of hydrogen. But the reply of the laboratories has always been clear and certain—that there is not in the facts the faintest foundation for such a theory.

Then came the discovery of the spectral analysis, and men thought that with an instrument of such inconceivable delicacy we should at last find out something as to the nature of the atom. The result has been wholly disappointing. Spectral analysis in the hands of Dr. Huggins and Mr. Lockyer and others has taught us things of which the world little expected to be told. We have been enabled to measure the speed with which clouds of blazing hydrogen course across the surface of the sun; we have learnt the pace—the fabulous pace—at which the most familiar stars have been for ages approaching to, or receding from, our planet, without apparently affecting the proportions of the patterns which, as far as historical record goes back, they have always delineated on the evening sky. We have received some information about the elementary atoms themselves.

In the last few years the same enigma has been approached from another point of view by Prof. Mendeléeff. The periodic law which he has discovered reflects on him all the honour that can be earned by ingenious, laborious, and successful research. He has shown that this perplexing list of elements can be divided into families of about seven, speaking very roughly: that those families all resemble each other in this, that as to weight, volume, heat, and laws of combination the members of each family are ranked among themselves in obedience to the same rule. Each family differs

from the others; but each internally is constructed upon the same plan. It was a strange discovery—strangest of all in its manifest defects. For in the plan of his families there were blanks left; places not filled up because the properly constituted elements required according to his theory had not been found to fill them. For the moment their absence seemed a weakness in the professor's idea, and gave an arbitrary aspect to his scheme. But the weakness was turned into strength when, to the astonishment of the scientific world, three of the elements which were missing made their appearance in answer to his call. He had described beforehand the qualities they ought to have; and gallium, germanium, and scandium, when they were discovered shortly after the publication of his theory, were found to be duly clothed with the qualities he required in each. This remarkable confirmation has left Mendeléeff's periodic law in an unassailable position. But it has rather thickened than dissipated the mystery which hangs over the elements.

The discovery of these co-ordinate families dimly points to some identical origin, without suggesting the method of their genesis or the nature of their common parentage. If they were organic beings all our difficulties would be solved by muttering the comfortable word "evolution"—one of those indefinite words from time to time vouchsafed to humanity, which have the gift of alleviating so many perplexities and making so many gaps in our knowledge. But the families of elementary atoms do not breed; and we cannot therefore ascribe their ordered difference to accidental variations perpetuated by heredity under the influence of natural selection. The rarity of iodine, and the abundance of its sister chlorine, cannot be attributed to the survival of the fittest in the struggle for existence. We cannot account for the minute difference which persistently distinguishes nickel from cobalt by ascribing it to the recent inheritance by one of them of an advantageous variation from the parent stock.

The upshot is that all these successive triumphs of research—Dalton's, Kirchhoff's, Mendeléeff's, greatly as they have added to our store of knowledge, have gone but little way to solve the problems which the elementary atoms have for centuries presented to mankind. What the atom of each element is—whether it is a movement, or a thing, or a vortex, or a point having inertia; whether there is any limit to its divisibility, and, if so, how that limit is imposed; whether the long list of elements is final; or whether any of them have any common origin—all these questions remain surrounded by a darkness as profound as ever. The dream which lured the alchemists to their tedious labours, and which may be said to have called chemistry into being, has assuredly not been realised; but it has not yet been refuted. The boundary of our knowledge in this direction remains where it was many centuries ago.

The next discussion to which I should look in order to find unsolved riddles which have hitherto defied the scrutiny of science would be the question of what is called the ether. The ether occupies a highly anomalous position in the world of science. It may be described as a half-discovered entity. I dare not use any less pedantic word than entity to designate it, for it would be a great exaggeration of our knowledge if I were to speak of it as a body or even as a substance. When, nearly a century ago, Young and Fresnel discovered that the motions of an incandescent particle were conveyed to our eyes by undulation, it followed that between our eyes and the particle there must be something to undulate. In order to furnish that something the notion of the ether was conceived, and for more than two generations the main, if not the only, function of the word "ether" has been to furnish a nominative case to the verb "to undulate." Lately our conception of this entity has received a notable extension. One of the most brilliant of the services which Prof. Maxwell has rendered to science has been the discovery that the figure which expressed the velocity of light also expressed the multiplier required to change the measure of static or passive electricity into that of dynamic or active electricity. The interpretation reasonably affixed to this discovery is that, as light and the electric impulse move approximately at the same rate through space, it is probable that the undulations which convey them are undulations of the same medium. And as induced electricity penetrates through everything, or nearly everything, it follows that the ether through which its undulations are propagated must pervade all space, whether empty or full, whether occupied by opaque matter or transparent matter, or by no matter at all. The attractive experiments by which the late Prof. Hertz illustrated the electric vibrations of the ether will only be alluded to by me, in order that I may express the regret deeply and generally felt that death should have terminated prematurely the scientific career which had begun with such brilliant promise and such fruitful achievements. But the mystery of the ether, though it has been made more fascinating by these discoveries, remains even more inscrutable than before. Of this all-pervading entity we know absolutely nothing, except this one fact: that it can be made to undulate. Whether, outside the influence of matter on the motion of its waves, ether has any effect on matter or matter upon it, is absolutely unknown. And even its solitary function of undulating ether performs in an abnormal fashion which has caused infinite perplexity. All fluids that we know transmit any blow they have received by waves which undulate backwards and forwards in the path of their own advance. The ether undulates athwart the path of the wave's advance. The genius of Lord Kelvin has recently discovered what he terms a labile state of equilibrium, in which a fluid that is infinite in its extent may exist, and may undulate in this eccentric fashion without outraging the laws of mathematics. I am no mathematician, and I cannot judge whether this reconciliation of the action of the ether with mechanical law is looked upon as a permanent solution of the question, or is only what diplomatists call a *modus vivendi*. In any case it leaves our knowledge of the ether in a very rudimentary condition. It has no known qualities except one, and that quality is in the highest degree anomalous and inscrutable. The extended conception which enables us to recognise ethereal waves in the vibrations of electricity has added infinite attraction to the study of those waves, but it carries its own difficulties with it. It is not easy to fit in the theory of electrical ether waves with the phenomena of positive and negative electricity, and as to the true significance and cause of those counteracting and complementary forces to which we give the provisional names of negative and positive, we know about as much now as Franklin knew a century and a half ago.

I have selected the elementary atoms and the ether as two instances of the obscurity that still hangs over problems which the highest intellects have been investigating for several generations. A more striking but more obvious instance still is life—animal and vegetable life—the action of an unknown force on ordinary matter. Biology has been exceptionally active and successful during the last half-century. Its triumphs have been brilliant, and they have been rich enough not only in immediate result but in the promise of future advance. Yet they give at present no hope of penetrating the great central mystery. Men may, perhaps, have overrated the progress of nineteenth-century research in opening the secrets of nature; but it is difficult to overrate the brilliant service it has rendered in ministering to the comforts and diminishing the sufferings of mankind.

If we are not able to see far into the causes and origin of life in our own day, it is not probable that we shall deal more successfully with the problem as it arose many million years ago. Yet certainly the most conspicuous event in the scientific annals of the last half-century has been the publication of Mr. Darwin's work on the "Origin of Species," which appeared in 1859. In some respects, in the depth of the impression which it made on scientific thought, and even on the general opinion of the world, its momentous effect can hardly be overstated. But at this distance of time it is possible to see that some of its success has been due to adventitious circumstances. It has had the chance of enlisting among its champions some of the most powerful intellects of our time, and perhaps the still happier fortune of appearing at a moment when it furnished an armoury of weapons to men, who were not scientific, for use in the bitter but transitory polemics of the day. But far the largest part of its accidental advantages was to be found in the remarkable character and qualifications of its author. The equity of judgment, the simple-minded love of truth, and the patient devotion to the pursuit of it through years of toil and of other conditions the most unpropitious—these things endeared to numbers of men everything that came from Charles Darwin apart from its scientific merit or literary charm. And whatever final value may be assigned to his doctrine, nothing can ever detract from the lustre shed upon it by the wealth of his knowledge and the infinite ingenuity of his resource. The intrinsic power of his theory is shown at least in this one respect, that in the department of knowledge with which it is concerned it has effected an entire revolution in the methods of research. Before his time the study of living nature had a tendency to be merely statistical; since his time it has become predominantly historical. The deepest obscurity still hangs over the origin of the infinite variety of life. Two of the strongest objections to the Darwinian explanation appear still to retain all their force.

I think Lord Kelvin was the first to point out that the amount of time required by the advocates of the theory for working out the process they had imagined could not be conceded without assuming the existence of a totally different set of natural laws from those with which we are acquainted. His view was not only based on profound mechanical reasoning, but it was so plain that any layman could comprehend it. Setting aside arguments deduced from the resistance of the tides, which may be taken to transcend the lay understanding, his argument from the refrigeration of the earth requires little science to apprehend it. Basing himself on these considerations, Lord Kelvin limited the period of organic life upon the earth to 100 million years, and Prof. Tait, in a still more penurious spirit, cut that 100 down to 10. But, on the other side of the account stands the claims of the geologists and biologists. I see, in the eloquent discourse of one of my most

Digitized by Google

recent and most distinguished predecessors in this Chair, Sir Archibald Geikie, that the controversy is still alive. The mathematicians sturdily adhere to their figures, and the biologists are quite sure the mathematicians must have made a mistake. I will not get myself into the line of fire by intervening in such a controversy; but until it is adjusted, the laity may be excused for returning a verdict of "not proven" upon the wider issues the Darwinian school has raised.

The other objection is best stated in the words of an illustrious disciple of Darwin, who has recently honoured this city by his presence—I refer to Prof. Weismann. We cannot demonstrate the process of natural selection in detail; we cannot even, with more or less ease, imagine it. It is purely hypothetical. Variation by artificial selection, of course, we know very well: but the intervention of the cattle breeder and the pigeon fancier is the essence of artificial selection. The biologists do well to ask for an immeasurable expanse of time, if the occasional meetings of advantageously varied couples from age to age are to provide the pedigree of modifications which unite us to our ancestor the jelly-fish.

It seems strange that a philosopher of Prof. Weismann's penetration should accept as established a hypothetical process the truth of which he admits that he cannot demonstrate in detail, and the operation of which he cannot even imagine. The reason that he gives seems to me instructive of the great danger scientific research is running at the present time—the acceptance of mere conjecture in the name and place of knowledge, in preference to making frankly the admission that no certain knowledge can be attained. "We accept natural selection," he says, "because we must—because it is the only possible explanation that we can conceive." As a politician, I know that argument very well. In political controversy it is sometimes said of a disputed proposal that it "holds the field," that it must be accepted because no possible alternative has been suggested. In politics there is occasionally a certain validity in the argument, for it sometimes happens that some definite course must be taken, even though no course is free from objection. But such a line of reasoning is utterly out of place in science. We are under no obligation to find a theory, if the facts will not provide a sound one. To the riddles which nature propounds to us, the profession of ignorance must constantly be our only reasonable answer. The cloud of impenetrable mystery hangs over the development, and still more over the origin, of life. If we strain our eyes to pierce it, with the foregone conclusion that some solution is and must be attainable, we shall only mistake for discoveries the figments of our own imagination.

Prof. Weismann adds another reason for his belief in natural selection which is certainly characteristic of the time in which we live. "It is inconceivable," he says, "that there should be another principle capable of explaining the adaptation of organisms without assuming the help of a principle of design." The whirligig of time assuredly brings its revenges. Time was, not very long ago, when the belief in creative design was supreme. Even those who were sapping its authority were wont to pay it a formal homage, fearing to shock the public conscience by denying it. Now the revolution is so complete that a great philosopher uses it as a *reductio ad absurdum*, and prefers to believe that which can neither be demonstrated in detail, nor imagined, rather than run the slightest risk of such a heresy. I quite accept the Professor's dictum that if natural selection is rejected we have no resource but to fall back on the mediate or immediate agency of a principle of design. In Oxford, at least, he will not find that argument is conclusive, nor, I believe, among scientific men in this country generally, however imposing the names of some whom he may claim for that belief. I would rather lean to the conviction that the multiplying difficulties of the mechanical theory are weakening the influence it once had acquired. I prefer to shelter myself in this matter behind the judgment of the greatest living master of natural science among us, Lord Kelvin, and to quote as my own concluding words the striking language with which he closed his address from this chair more than 20 years ago: "I have always felt," he said, "that the hypothesis of natural selection does not contain the true theory of evolution, if evolution there has been in biology. . . . I feel profoundly convinced that the argument of design has been greatly too much lost sight of in recent zoological speculations. Overpoweringly strong proofs of intelligent and benevolent design lie around us, and if ever perplexities, whether metaphysical or scientific, turn us away from them for a time, they come back upon us with irresistible force, showing to us through nature the influence of a free will, and teaching us that all living things depend on one everlasting Creator and Ruler."

Telegraphs in Japan.—No less than 1,181 tons of telegraph wire were imported into Japan last year through Yokohama, as against 1,053 tons in 1892.

ELECTRIC POWER, HEATING AND LIGHTING.*

BY G. BINSWANGER, M.I.E.E.

The author stated that his object was to show some of the latest developments of Electrical Science, mainly in the field of domestic appliances, with a view of discussing the advantages they may offer to architects seeking to improve the present ordinary methods of motive power, heating, lighting, ventilating, cooking, &c. He wished at the same time to indulge in a few speculations as to how far such developments of electrical apparatus and their possible improvements and extensions might influence the education of the future architect, and as to how he will take advantage of them for improving our houses, and the consequential alteration in his plans and structures of our future buildings.

The author proceeded to explain the theory and action of electric motors by means of simple experiments, and alluded to the back pressure and self-regulating properties of motors. After briefly discussing the peculiar conditions of alternate-current motors, he directed attention to some of the main advantages of an electric motor over other motors, such as steam, gas, oil, or water engines.

Simplicity.—There is absolutely no technical skill required to handle an electric motor. Turn a switch, and it starts or stops; turn a multiple switch, and by means of resistances the speed can be varied. No knowledge of pressure or water gauges, of valves, exhaust, &c., is required.

Attendance.—The electric motor may be said to require absolutely no attendance beyond occasional oiling of its bearings; no stoking of boilers; no cleaning; hardly any repairs. It adjusts itself to any load within its range.

Range of Power.—A feature of the electric motor is the ease with which it may be designed to have the power of a watch, or that of the largest locomotive.

Compactness.—In proportion to the power developed in an electric motor, the space it occupies is extremely small. Its size depends largely on the speed its armature is intended to revolve at, but even at low speeds an electric motor is smaller than any other motor.

Safety.—A steam engine, with its dangerous boiler, a gas or oil engine subject to explosion, could not well be placed by an architect inside a house. No fear of danger of any kind need deter you from putting an electric motor right into a drawing-room, as it is so absolutely safe.

Position.—An electric motor can be placed anywhere conveniently in a house; it requires little fixing, hardly any foundation; it is not unsightly; and, owing to the fact that it can be started and stopped from any distance, it can be placed in ordinarily inaccessible places.

Cleanliness.—It is absolutely clean, not even the oiling of its bearings need cause any dirt or mess. Can we say this of other motors?

Noiselessness.—Compared to a gas or oil engine, an electric motor is quite noiseless. Some of the alternating motors at high frequency issue a kind of hum, but direct-current motors are quite noiseless.

Efficiency.—The efficiency of electric motors of the larger sizes is very good, and ranges from 60 to 80 per cent. As they are self-regulating there is little waste when run on small loads, but their main efficiency and economy lies in the fact that they consume power only when doing work.

With such a convenient and efficient motor at the disposal of the architect, they might expect to see it figure largely in many of his plans and undertakings. It must influence his future considerations in building our dwellings, public edifices, and factories.

Factories.—The author felt confident that the invention of the electric motor would revolutionise the planning and building of our factories. At present, mills and factories for the most part are driven by steam power, and it is essential to bring the machines as near the source of power as possible, in order to avoid the cost and waste inherent in transmission by shafting and belting. No such consideration need affect the designing of factories in the future. The power of the electric current can be transmitted easily, cheaply, and practically without loss through two wires; the motors can be placed directly near or upon the machines to be driven.

Home Industries.—Not only will the factory buildings themselves be constructed on different lines owing to this fact, but he looked forward to an increase of home industry in which the several members of a family may be employed. From a social and economical point of view, this will prove a great advantage to many an industry and to many a community. It will, of course, receive due consideration in planning the construction of our workmen's dwellings. He looked forward also to the employment of electric motors in large public buildings, hotels, and in private houses.

* Abstract of a Paper read before the "Congress of Public Health" (Engineering and Building Construction Section), July 31, 1894.

Digitized by Google

Ventilation.—He believed this was an important question for architects, and one which has not yet found a definite solution. The usefulness of the electro-motor in driving fans for ventilation has been again and again demonstrated and recognised—there can be no doubt that it will be employed largely for this purpose in the future, and will therefore have a considerable influence on the construction of buildings that require proper ventilation.

Lifts, Cranes and Trams.—At present lifts are only used in large buildings, because the power required is costly, or requires room, or cannot be obtained conveniently. No doubt, with such a source of power as the electric current within the reach of private houses, they might look forward to seeing lifts, cranes, and other methods of mechanical conveyance introduced into smaller houses. He supposed the want of such mechanical conveyance was now influencing the construction of many a house—why should the kitchen be near the dining room if we can get our dishes sent into the room by merely pushing a button?

Electric cranes have done good work in docks, and are much preferred to steam cranes. They will, no doubt, be largely employed in many of the operations necessary in the construction of buildings.

Many other instances could be cited to prove the usefulness of the electric-motor, and he could not urge too strongly upon architects the desirability of studying this question, and employing the electric-motor wherever possible.

HEATING BY ELECTRICITY.

Imagine a house built without flues, without chimneys, without hot-water pipes, and yet perfectly heated, perfectly ventilated, and with perfect cooking arrangements! Such a house could be built to-day, if we call electricity to our aid. Many such houses, no doubt, will be built within a not too distant period. Imagine the question of smoke abatement solved in this way!

Heating by electricity is no new invention, in fact every current flowing through a conductor produces heat in proportion to the resistance of such conductor, expressed by the law C^2 R., or heat equals the square of the current multiplied by the resistance. The application of such heating to industrial and domestic uses on anything like a practical scale is comparatively new, scarcely two years old. It is the natural outcome of the fact that we can procure in our houses a practically unlimited supply of current.

Just as in the electric lamp, so in the case of electrical heating apparatus, precautions must be taken against the undue burning up of the resistances, and this is done by embedding them in a substance which is a non-conductor of electricity, which also protects it from oxidation, and at the same time will, by its close proximity to the surface to be heated, conduct away readily the heat produced in the wire resistance. This substance is either refractory cement or vitreous enamel. To heat the atmosphere in rooms, radiators or stoves are made; they could heat either by radiation or convection.

The author exhibited such a radiator. The heat produced in the wire resistance embedded in the cement was transmitted to an iron surface having many projections and blackened. It required a current of 10 amperes at 100 volts to warm a room of about 3,000 cubic feet. This method of heating the atmosphere by electricity is still too young to predict the success of its ultimate employment, in preference to heating by coal or gas.

What he wished to demonstrate was, that it could be done, and that such heating would present certain qualities which are not possessed by the present methods at our disposal, and which are mainly: There is no combustion, consequently there is no air required and no oxygen consumed. There is no flue wanted. The apparatus can be placed in many positions impossible with the old arrangements. The heat can be subdivided, and more easily directed and concentrated upon the space to be heated. It is perfectly clean. It is always ready, and requires no manual labour for starting.

Cooking.—The application of electricity to cooking operations will no doubt effect quite a revolution in our households, and will influence the planning of our buildings accordingly. All apparatus and utensils usually employed for cooking are now made in the manner already explained. Ovens are fitted with small radiators at the sides and top. An "electric oven" is, in contrast to the blackness of coal and gas ovens, made of bright brass or tinned iron; as bright as possible inside to procure reflection of heat, and bright and highly polished outside to prevent radiation.

Kettles, saucepans, grillers, toasters, fish kettles, &c., were shown to the audience. These have the resistance wires embedded in cement underneath on the outer surface of their bottom plates, and are thus brought into close proximity to the liquid or material to be heated, so that the heat is at once transmitted thereto, and, by having such articles as kettles and pans polished, extremely little loss occurs through radiation. All the usual necessary operations of cooking can be performed by electricity, and he had it on the authority of experts, including City aldermen, that the quality and perfection of electrically cooked viands is indisputable, and that the method is far superior to our present old-fashioned ones.

The employment of electrical heating for other purposes in our houses had not been neglected. Ladies can have their electric hair curlers, gentlemen their electric shaving pots. A great future lies open to electrical heating in industrial applications. He made many irons for laundries, tailors, as well as for domestic use, and they are much appreciated as offering great advantages. Another interesting application is that of electrically-heated branders, for packing cases, bacon, and branders for bookbinding.

In short, he affirmed that there was not a single operation performed in our daily life by coal or gas that could not also be performed by electricity, and that mostly in a superior and more advantageous manner.

Electric Lighting.—The author wished to seize this opportunity of talking to architects, to say a few words upon a subject in connection with electric lighting, a subject which, to his knowledge, had so far received but little ventilation before architects, to whom it must mean a good deal. The method adopted in this and many other countries is to run two wires in wood casing, having two grooves in it. This method is a compromise between the electrical engineer and the fire-insurance inspector; the third party, who ought to have a voice in the matter has never been consulted—I mean the architect. I had heard many architects complain that this method is one which does not commend itself to them; it is difficult, and sometimes impossible, to provide for it in new houses, and often disfigures the walls of existing buildings, to be installed with electric wires. By some it is looked upon as a necessary evil. This need not be so. He felt confident that a departure from present arrangements could be effected which would be appreciated both by the builder and the architect. He felt sure that the co-operation of the architect and electrical engineer would eventually produce such a modification as is felt to be desirable, and even necessary, by the electrical profession itself. He thought that all architects should acquaint themselves with the elements of applied electricity; every architect should have a fair conception of the meaning of such terms as "volt," "ampere," "ohm" and "watt." He ought to be familiar with the properties of wires, their carrying capacities, their resistances, and of materials used for insulating those wires necessary to fit them for use in electrical installations. A knowledge of these and similar subjects would be of considerable service to him in preparing his plans for our modern buildings, which will be all the better for being supplied with all the comforts and luxuries capable of being bestowed upon us by making electricity our servant.

Cost.—He had so far refrained from referring to what would be the cost of employing the electric current for the purposes of which he had been speaking. Doubtless, they would say, here lies the crux of the whole question. There can be no doubt that the operations can be performed; but they would be of little practical value if their cost should be beyond their clients' means. His reply to this was that the cost is not excessive, or beyond the means of the moderately rich, even at the price at which the current is being generally sold; but there are indications and grounds sufficient at hand that might lead them to expect that one day electricity will also supply energy for light, power and heat to the poor.

They might with confidence look forward to being able to obtain, at a not too distant period, cheap electric energy, concurrently with perfect and economical apparatus, for employing it for lighting, power, and heating. In view of this, architects will do well to contribute to the early and general adoption of electricity for such purposes, and thorough co-operation of architects and electrical engineers will, he felt confident, be of great value, and conducive to the furtherance of the objects which this Congress of Public Health has at heart.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 28, 1894.

The North-Western Electrical Association.—This Association held a successful Convention at St. Paul, on July 18th, 19th, and 20th, at which several Papers of value were read. This is but the second meeting of this Association, and its success will probably lead to the formation of other local bodies, thus probably detracting from the importance of similar national organisations. The large attendance is the more notable from the inconvenience in travelling on account of the railroad difficulties in the West, and the exceedingly depressed state of business.

Digitized by Google

Municipal Ownership.—Mr. Allen R. Foote read a Paper at the St. Paul Convention on "Municipal Ownership." His argument, in part, was that with human nature as imperfect as it is better results can be obtained from the private operation of non-competitive monopolies than by their political management. He also affirms that only through private ownership can the economic principles involved be fully realised. He argues for the legislative enactment of laws which, while favouring private ownership, will yet only permit the economic advantages inherent in such ownership to be enjoyed, thus giving the public the full benefit they would receive through public ownership, added to the advantages that would accrue through proper business management.

Incandescent Lamp Economy.—Mr. A. D. Page, manager of the Edison Incandescent Lamp Department, read a Paper at the above meeting on "Incandescent Lamps, their Use and Abuse," in which he shows that lamps should be judged by some better standard than life, and insists upon the great importance of uniform voltage to obtain the highest results of economy from incandescent lamps, and condemns the practice of American central stations of raising their voltage to keep up the candle-power of old lamps. He states that the only practical method of keeping the average candle-power of lamps on a station at a point which will be satisfactory to consumers, or on a competitive basis with other methods of lighting, is to keep records of the average life on the entire station where free renewals are furnished, and then to take out of the sockets and break up all lamps which are dim, by this means keeping down the average life to whatever constant is decided as the best under local conditions. Where lamps are sold to customers, to keep the candle-power of lamps in use on the circuit of a central station at a point which will insure satisfaction is a difficult problem. Whether the customer is on a meter or on a contract basis, it is poor economy for him to keep lamps in his sockets which are giving only 50 per cent. of their initial light; but, for the company which sold him the lamps and supplies him with current to call his attention to the fact that lamps in his sockets are giving only about eight candles, and attempt to sell him lamps at 50 or 60 cents each, is not likely to bring about the desired result. To meet the above difficulties a number of central stations in different parts of the country are now selling lamps at retail to their customers at cost and a few stations even below cost, at the same time doing all in their power to prove to them that only by a liberal use of lamps can they obtain the greatest amount of light for a given expenditure of money. At the present price of lamps, where fuel is high and the customers' bills are made up on the basis of lamp hours, it would, without question, pay the station to use high economy lamps, breaking them at a point which insures satisfaction as to average life, and keeping the average life comparatively short. It is urged by Mr. Page that whatever economy or make of lamp it is decided to use, by no means can the efficiency of the station be so greatly increased as by making every possible effort in the direction of maintaining a constant voltage at the lamps.

Cost of Producing Electrical Energy.—At the same meeting Mr. B. J. Arnold read a Paper on the cost of producing electrical energy. He states that with a properly-designed direct-connected plant we may reasonably expect to deliver to the consumer from stations having a capacity of not over 1,500 kilowatts, electrical energy for 5c. per kilowatt hour, which includes total cost of production and depreciation of plant; but excludes capital charges and profit, the cost of good coal being $2. 50c. per ton. In larger stations, he says that the cost can be brought down to 3½c., and quotes a statement to the effect that at Cologne, Hanover, and Dusseldorf electrical energy is delivered at 6·65c., 5·2c., and 4·54c. respectively. In this connection the figures in the report of the Massachusetts Electric Light Commissioners are of interest for comparison with Mr. Arnold's statement. In the large central stations of that State, which are about the only ones that pay dividends, it is shown that the ratio of operating expenses to the income from the sale of current is over 0 6, which brings up the cost to over 8c. per kilowatt hour, operating expenses alone being considered, depreciation and capital charges being excluded; and this seems to be about as good a result as is now achieved in this country.

LEGAL INTELLIGENCE.

Woodhouse and Rawson United (Limited).

MONDAY, AUGUST 6TH.

Mr. F. L. RAWSON, further examined by the Official Receiver, said: The circular dated February 12, 1891, which related to the issue of debenture stock—which, it was stated, would be a first charge on the whole of the Company's undertaking—was only issued to the holders of the existing debenture stock, who could not possibly be misled by the omission of the qualification that the new debenture stock would be a first charge only after the existing debentures had been paid off. The prospectus for the new issue was in all cases sent out with the circular, and therein the qualification was plainly stated. He could not absolutely say that the Directors saw the actual circular sent out, but they approved a draft in which alterations were subsequently made; he would not, however, have altered any important principle in the circular without going to the Board.

By Mr. Pilling: The sums paid to him by the Phœnix Trust Company did not constitute a repayment in full of the loans he had made to that Company; but they were payments on account, subsequent to which he made further advances. The Company was never out of his debt, so far as he recollected. Some of the payments were on account of expenses; certainly much more than £5,000 was paid to him in that way, probably from £15,000 to £20,000. He repeated that the United Company took no risk in connection with the formation of the American Elmore Company. They entered into an agreement under which they were to pay all the expenses of the promotion; but the shares were underwritten, and about £15,000 had been subscribed before that agreement was entered into. The Phœnix Company underwrote the capital, the agreements being entered into at the same time; one would not have been made without the other. He should doubt the statement that at this time the Phœnix Company was indebted to the United to the extent of £7,000. The Phœnix Company performed other services for the consideration they received, which was three-fourths of the profits made; there was an immense amount of work which they did in connection with the Elmore Companies, and to give an idea of the extent of it he might state that they must have spent between £200 and £300 in telegrams and cablegrams alone. Probably the share of the Phœnix Company in the profits in the American Elmore did amount to £34,000 in shares and cash. Approximately one-fourth of these profits should have come to witness under ordinary circumstance; but, as a matter of fact, it did not. His recollection was that he received about £200 in fees from the Phœnix Company, and probably the other Directors received a like amount. The United Company did not apply for any shares in the French Elmore Company. Witness and Mrs. Rawson each applied for a thousand shares; but as only a certain number of shares was set apart for the shareholders of the United, both withdrew their applications. He subsequently went into the market and bought some of the shares at a premium in order to have an interest in the Company. Probably the Phœnix Company received about the same amount from the formation of this Company as from the American Company. Whatever it was, they received it in cash, but laid it out again in shares, because they thought a very large profit would accrue upon those shares. The United Company was not consulted with regard to this investment in French Elmore shares. Quite likely the United Company became possessed of £20,000 worth of debentures in the Austro-Hungarian Company, this being their share of the commission on the sale of the German patents. Upon the distribution of the assets of the Phœnix Company, a large parcel of Deferred shares in the American Elmore Company fell to the United. It had been recently stated by Mr. William Elmore to the Foreign Elmore Company that the money would be received in full on those Deferred shares. It was untrue that the other shareholders in the Phœnix Company received Priority shares in the American Elmore Company, whilst Witness and the United Company had all the Deferred shares. The division of the assets was made after a long contest, lasting until three o'clock one morning, in which he fought hard for a fairer division than was at first proposed. When the settlement was finally made it was put before the Board of the United, and agreed to. The United got a large amount of the Priority shares. With regard to the estimate of profits, £75,000, which appeared in the original prospectus, that sum was probably arrived at after discussion between the Board of the Limited Company and the new Directors. Witness was quite prepared to accept his share of the responsibility for that estimate. As a matter of fact, it was a wonderfully accurate one, and realised more than the sum stated. Mr. Pixley examined the estimate, and reported that it appeared to be a fair one. He was almost certain that the estimate was actually made by the new Directors upon the figures he placed before them, but he could not be absolutely certain.

By the Registrar: The figures he submitted included the valuation of the shares, which were taken at the price of the Stock Exchange quotations.

By Mr. Pilling: The Limited Company had not £314,000 to divide amongst its shareholders at the time of the liquidation, and the balance-sheet produced did not show a sum sufficient to pay the shareholders back their money four or five times over. With regard to the loans made to him by the United Company, £28,000 was for the purpose of purchasing Preference shares, for which he paid 5s. premium. The shares were left with the Company until he paid for them. He still held those shares, with the exception of 100 which he gave to Mr. North as a present, and 5,000 which he gave, also as a present, to his brother, Mr. Stepney Rawson, who had not, he considered, been adequately paid for the work he had done. He obtained the consent of the Board before transferring those shares. He did not think he had sold a single share, but had steadily increased his holding in the United Company. As a further security for the loan made to

Digitized by Google

him the Company had a charge on his interest in the founders' shares. There was an arrangement by which he assigned the £10,000 voted to him by the shareholders of the Limited, but which he had not received, to the United Company. The reason for that was, that there was an intention on the part of the liquidators of the Limited to conceal the fact that the United owed them a certain amount, until by revealing it they could secure an advantage. He was aware of this, and assigned the £10,000 to the United in order that when the liquidators of the Limited sprung their surprise, they might be met with the answer that instead of the United owing them anything they were in the debt of the United. As a matter of fact, the Limited tried to bring off their surprise, but the countermine of the £10,000 settled their mine. The Directors of the United, whilst he was in their debt, never allowed him to take any cash by way of dividends on his shares, or in any other way unless he gave them good reasons why it was necessary that he should have the cash. For instance, he paid for the Okonite shares out of the dividends due to him. He took 10,000 Ordinary shares in the Okonite Company in order to help the United Company; he bought them in the market. The Stock Exchange was not particularly favourable to any of the Companies they brought out, and in the absence of any actual transaction would call the shares at a discount; he, therefore, gave his brokers instructions to go in and buy up all shares offered at about par, and he secured £10,000 worth in that way. It was a well-known fact that in the absence of any transaction of that kind jobbers in the market could practically smash a new company. At that date he did not think he would have any difficulty in paying for the shares. He went to the Directors, and told them he had arranged to borrow £5,000, and if they would lend him the debentures he would hand over as security the shares he had bought. Later on, as he could not pay them back, they said they must debit him with the amount at par, notwithstanding that at that time they were selling at a discount. The result of the whole of the transactions was not to leave a balance of £32,000 against him, but left him a creditor.

The REGISTRAR directed witness's attention to one or two points which it was desirable that he should bear in mind in making his statement, particularly in regard to the powers taken to carry on the financial branch of the business. Witness had spoken of the Memorandum of Association as giving a specially wide power in this respect; but he found upon reference to a large number of prospectuses and Memoranda of Association, that it was practically a common form; in 70 out of 93 which he had examined he found a clause practically identical with that pointed to in this case.

It having been arranged that any further questions by counsel for the Directors should be deferred until after witness had made his statement,

Mr. RAWSON proceeded to give a brief history of the formation of the various companies. He said he was engineer to the first electric lighting company, which was formed in 1879, and went into partnership with Mr. Woodhouse in 1881. Their business was divided into four branches—manufacturing, supply, contract, and work in connection with patents. The business rapidly increased, and they acquired a considerable reputation. In order to keep up with the increase of business the Woodhouse and Rawson Electric Manufacturing Company was formed in 1885, the partners being paid entirely in shares for the business. Later in the same year the merchants' business was formed into a Company called the Woodhouse and Rawson Electric Supply Company, of Great Britain, Messrs. Woodhouse and Rawson being again paid in shares. The Woodhouse and Rawson Electric Contract and Maintenance Company was formed about two years later to take over the northern portion of the business for the installation of electrical works, being practically a partnership with the Crossley Telephone Company, a very strong local company. Owing to the action brought by the Edison-Swan Company with regard to incandescent lamps, an immense amount of work fell on the shoulders of witness, and it was impossible for him to give the necessary attention to the rapidly-growing business, and in 1887 Woodhouse and Rawson (Limited) was formed in order that the assistance of Mr. A. Hoster as joint Managing Director might be obtained. Mr. Hoster was a mechanical engineer, and his duty was more especially to look after the manufacturing business. This had developed from the manufacture of incandescent lamps into the manufacture of every description of light electrical apparatus. Mr. Woodhouse died, and the business of Woodhouse and Rawson (Limited) developed so rapidly that Mr. Hoster found he could give no time to the manufacturing branch, and therefore, in 1888, as the manufacture of lamps had been regained, witness endeavoured to amalgamate the manufacturing business with several other manufacturing companies, and an arrangement was ultimately made to amalgamate the business of C. L. Baker and Co. and the Woodhouse and Rawson Manufacturing Company. The proposed new directors insisted, against witness's wish, upon including the business of Woodhouse and Rawson (Limited), which had gradually been taking up work in connection with patents and inventions. Negotiations went on with regard to the amalgamation all through the end of 1888, and at the beginning of 1889 the new Directors insisted that the Supply Company should also be included. Witness did his best to prevent the amalgamation of the whole of the companies, but Sir John Stokes backed up the new Directors on the ground that his experience was that the companies would be much more economically and better managed if they were amalgamated; further, Sir John Stokes wanted to get rid of the Founders' shares in Woodhouse and Rawson (Limited). Originally it had been contemplated to include in the sale of Woodhouse and Rawson the Hammersmith Electric Lighting Act, together with various other companies; these were gradually eliminated by the new Directors, on the ground, partly, that the prices were too high, and partly on the ground that insufficient evidence was put before them with regard to the possible future of the businesses. Originally the profits of Woodhouse and Rawson (Limited) were to have been taken over from the end of July, 1888. Owing to the very long time it took the Directors to make their investigations, Woodhouse and Rawson (Limited), when they had sold the foreign Elmore patents to the Société des Métaux for £700,000 in the early part of 1889, refused to hand over these profits. This sale was not actually carried out, owing to the difficulties that the Société des Métaux got into; and ultimately the foreign Elmore patents were sold to an English company. The new Directors then insisted that the profits for the year, instead of being handed over, should be deposited as security for the guaranteed payment of a dividend of 10 per cent., which was afterwards raised by the new Directors to 15 per cent. for three years. During the great delay that took place in the negotiations, the position of the Manufacturing Company had not been improving, as proper arrangements could not be made for the management of it. Witness went to live at the works in order to be able to give a little time to them, and worked very hard to get it into a proper position. Witness stated to the new Directors that he did not expect to be able to pay a dividend from the industrial profits alone for the first three years; but he saw his way, from work in progress, to pay a dividend of 15 per cent., including the profits from the financial business. At the end of three years he thought the industrial portion alone would show sufficient profit to pay 5 per cent., while the reserve from the financial side would enable them to pay 10 per cent. until the industrial business had increased sufficiently. During the first year of the Company's operations witness worked such long hours that the Directors thought, considering his previous hard work, it was impossible for him to attend to both departments and, consequently, they appointed Mr. North as manager of the industrial branch of the business. Some time in 1891 Mr. North complained that he could not get his portion of the work done, owing to witness requiring to supervise everything that was being done. Witness stated that he did not trust Mr. North, but the Directors upheld Mr. North in his independent management. In November, 1891, it was found that Mr. North had betrayed the confidence reposed in him, and Mr. Stutchbury was appointed general manager, to get the industrial business into order. In the beginning of 1892 witness stated to the Board that the only thing, in his opinion, that could be done was to close all the branches of the business that were losing money, and to start the industrial business on a comparatively small scale, until it was thoroughly under way. Mr. Stutchbury reported that, with £15,000 working capital and all debts paid, he could make a success of the industrial portion of the business without cutting down the business in the way proposed. Witness stated that he could easily raise the amount required, but said that Mr. Stutchbury had not sufficient experience to act as manager. Witness urged his views as to reducing the business, and some of the Directors stated that, if those views were acted upon, they would not remain on the Board, as the Company was an industrial business, not a financial one, and that Mr. Stutchbury had definitely stated that he could make the industrial portion of the business a success, that the aim of the Directors had been always to increase the industrial portion of the business, and that they were not going to alter this. Witness warned the Directors of what the result would be, but agreed to carry out their views. Mr. Stutchbury found the task harder than he expected, owing to the position into which Mr. North had allowed the business to get, and it was not until the end of 1892 that the losses being made on the industrial portion of the business were substantially put an end to. The result of the year's working, however, was a heavy loss all round, notwithstanding that salaries were reduced by more than 50 per cent., and the Directors waived more than 50 per cent. of their fees. The action of the Edison-Swan Company resulted in a loss of £14,742, the loss at Kidsgrove was £17,784, whilst the loss in other departments, together with the large depreciation in plant, stock and tools, owing to the Edison-Swan action, amounted to £37,274. There was a large depreciation in the quoted prices of securities, amounting to over £26,000, so that, after paying expenses, there was a loss of £86,000, notwithstanding the interest on loans and investments received being over £7,000. At the general meeting of shareholders a committee of consultation was appointed to assist the Directors. Instead of endeavouring to do this, they sent out a circular which had misstatements of fact in it, the result being absolutely to prevent the Company carrying on its business, and accordingly it went into voluntary liquidation, which, afterwards, owing to the report of the Committee, was made a compulsory liquidation.

Touching on points suggested by the learned Registrar, the WITNESS said: Woodhouse and Rawson (Limited) did not care to go into the business of financing the Elmore business, and he found the money himself, and laid out a plan of operation for Mr. Elmore, who worked at the process until he made it the great success it ultimately became. Then he (witness) gave the Limited Company the benefit of his contract with Mr. Elmore—a certain percentage on what the patents might realise, retaining only the option on the ground that the option was not strictly the business of Woodhouse and Rawson (Limited); but when it became of the value o £30,000 he gave that up too. With regard to his commission, the first year he said he would not take the £14,000 which was due to him until the shares were realised, or, if the Board liked, he would take the shares themselves at the actual price at which they stood in the balance-sheet; he also stated that, now that they saw how successful the Company was, he was quite ready to cancel his engagement and enter into any other agreement they might wish. At the end of October, 1891, or in November, he offered to give up not only the 25 founders' shares he held in the Phœnix Company, but also the dividends he had received that year, if they thought it was an incorrect thing for their Managing Director to be interested in that Company in the way he was; but, looking to the large profits which the Company had made in consequence of the connection, they thought it was only right that he should retain the Founders' shares. Witness had never received a penny of promotion money in his life; and since the liquidation he had given the whole of his time to the affairs of the United Company. The owners of a very large industrial business offered him £5,000 to advise them in connection with the formation of a company, most of the capital for which was to be subscribed privately, and offered the Directors of the United to do the work in their name and hand the

Digitized by Google

profit over to them; but, as they felt it was not quite the sort of business they wished to take up, he did not accept the offer. His reason for mentioning these things was to show that throughout the existence of the Limited and United Companies he did everything he could to advance the interests of the Companies, without thinking of himself, excepting, that he hoped to ultimately reap the benefit of being the Managing Director of a successful company.

The REGISTRAR said he was bound to say that that was the impression which had been made upon his mind throughout this enquiry.

WITNESS proceeded to explain why he thought the prospectus was sufficiently clear as to the nature of the business it was intended to undertake, but said that at the outset it was never intended to devote so much attention as they ultimately did to the flotation of companies to work patents; but the success of their first venture was so great that very numerous offers were made to them in connection with the exploitation of other patents, and where they saw what they deemed a suitable opportunity in connection with electrical inventions they embraced it. There was clearly an opening for a business of that kind, as private firms did not care to take up inventions which would require a great deal of expenditure to work up, and they thought they saw their way to making considerable profits in that way, and by means which he considered might fairly be considered as fairly within the scope of an industrial business—the purchase of patents, the development of inventions, and the selling again of the patents at a profit. At the time they took up the Elmore patents the process was absolutely discredited, experts having declared strongly against it; but he was able subsequently to convince some of the leading people in the copper world, who were at first opposed to the idea that it was of any value, that it would do all that Mr. Elmore claimed for it, and was as great an advance in copper manufacture as was the Bessemer process in regard to steel. Witness repeated the explanation he had previously given as to Mr. Edmunds's valuation of the patents, saying that the report was written in his office at the dictation of Mr. Edmunds, blanks being left for the amounts, and afterwards filled in by Mr. Edmunds. He did not think that valuation was at all a satisfactory one, and he was greatly surprised at the smallness of some of the amounts. There was absolutely no ground for the suggestion that the original partnership of Woodhouse and Rawson was insolvent. The terms of the agreement with the British Electric Company were that the United were to receive for their patents in England £45,000 in debentures and £49,000 in Ordinary shares in the British Company; but that did not go through, as difficulties with the Edison and Swan Company arose. Witness had given very definite instructions, both to Mr. North and the head accountant, that the accounts between the Manufacturing Company, who were manufacturing for the British, and the British, who were selling to the Supply Company, should not in any way go through the books of the United But, notwithstanding those instructions, an account was opened in the books of the United, as if the United were manufacturing for the British Company's selling to the Supply Company. The solicitors, under advice, and from counsel, said that that would render the licence held by the British Company liable to be cancelled, as the British had no right to assign their power to manufacture and sell. He thought probably the reason why there was no mention of his report regarding the Phœnix Trust Company being produced at the Board meeting, was that it was produced during a period between the resignation of Mr. Dundas and the appointment of Mr. Stutchbury as secretary, and the clerk who entered the minutes during that time did not perform the duty efficiently. His secretary, who was assistant-secretary of the Company at the time, was in Court, prepared to swear that he himself took the report into the Board-room whilst the Board was sitting. Witness had not finished his statement when the Court rose, and it was agreed to hold a further sitting on Wednesday morning.

WEDNESDAY, AUGUST 8th.

Half-an-hour was spent in discussing the best mode of procedure with regard to Mr. F. L. Rawson's personal statement, and eventually it was arranged that there should be a further adjournment in order that he might complete a written statement and put it in.

Halifax and Huddersfield Union Banking Company (Limited) v. Andrews and Preece (Limited).

In the Chancery Division Mr. Justice Chitty gave judgment in this action, which was brought by plaintiffs as debenture-holders. A Receiver and Manager had already been appointed, and the Company now appeared, and admitted that they had no defence. His Lordship accordingly declared the plaintiffs entitled to an account of what is due for principal and interest, and to an inquiry as to what property was comprised in the debentures, with liberty to apply in Chambers as to a sale.

The Chicago Electric Elevated Railway.—In July the contract for the electrical equipment of the Metropolitan Elevated Railroad of Chicago was signed. The contract, which was given to the General Electric Company, requires two 1,500 kilowatt and two 800 kilowatt direct-connected generators, and 55 motor cars, with two 100-H.P. motors each. These motors will be sufficient to operate three car trains, and as the traffic requires longer trains in the future the number of motors will be increased to four to a car.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d. *The 1895 edition is in active preparation.*

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," being four Lectures delivered before the Royal Institution in April-May, 1894, by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is in preparation, and will shortly be published.

"THE WORK OF HERTZ."—The lecture delivered by Dr. O. J. Lodge at the Royal Institution on June 1st is being reprinted with corrections and additions, and many illustrations, and will shortly be ready, price 2s. 6d.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d (abroad 8s.). Prospectus on application.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

TENDERS INVITED.—The Corporation of Sunderland require a supply of grip boxes and connectors, tenders for which must be sent in by the 16th inst.

——— Tenders are invited for the best scheme, with cost, for lighting and heating a Presbyterian Church to be built in Newcastle-on-Tyne, and tenders are to reach the Secretary of the Building Committee, 20, Jesmond-road, Newcastle-on-Tyne, by the 15th inst.

——— Tenders are required for the ground work and concrete foundations for the new electric light central station to be erected in the Vastern-road, Reading. Persons willing to tender must communicate with Mr. Albury, 154, Friar-street, Reading.

——— Tenders are invited for the electric lighting of the glass houses at the Botanical Gardens, Edgbaston, Birmingham. Further particulars are given in our advertisement columns, and tenders must be sent in to Prof. Hillhouse, M.A., not later than September 1st.

TENDERS ACCEPTED.—The Electric Lighting Committee of the Belfast City Council have accepted the tender of Messrs. Marshall, Fleming and Jack for the supply and erection of an overhead travelling crane at the central electric lighting station.

——— Messrs. Babcock and Wilcox (Limited) have secured the contract for the additional boilers now being laid down at the Corporation electric light works, Waterloo-street, Glasgow.

——— The Public Library Committee of the Colchester Town Council have accepted the tender of Messrs. Christy Bros. for lighting the library buildings by electricity.

——— The tender of Messrs. Graham and Biddle, of 463, Oxford-street, London, W., has been accepted for the electric lighting of the residence of Mr. J. H. Renton, in Park-lane, for the sum of £534. The same firm have secured the tender for lighting, &c., the residence of Mr. F. Samuels, in Bryanston-square, W., for the sum of £445; and for a lighting installation and organ-blowing apparatus by electricity for the Wardens of the West London Synagogue, Upper Berkeley-street, W., for the sum of £189. For these installations Mr. W. J. Fryer acts as electrical engineer.

——— The Kingston-on-Thames Town Council have accepted the tender of Messrs. Robey and Co. for the gas engines for the electric lighting station for £126.

——— The Technical Education Committee of the Yarmouth Corporation have received the following tenders for lighting the School of Art, South Quay:—

Crampton and Co., Cambridge (accepted)	£57	18	6
Laurence, Scott and Co., Norwich	81	16	4
Crompton and Co., Chelmsford	86	5	0
Durrant, Yarmouth	96	17	11

SALE OF PLANT.—A large quantity of second-hand electric plant is advertised elsewhere for disposal, including engines, boilers, dynamos, E.P.S. cells, instruments, switchboards, &c., the whole

Digitized by Google

in good condition. Further particulars can be obtained of Mr. H. Cuthbert Hall, A.I.E.E., consulting engineer, 46, Queen Victoria-street, London, E.C.

SALES BY AUCTION.—Messrs. Fuller, Horsey, Sons and Cassell have received instructions to dispose of the extensive manufacturing premises at present occupied by Messrs. Latimer Clark, Muirhead and Co. (Limited), and also the plant and machinery, which is being sold under the liquidation by order of the Receiver, Mr. James Worley. The sale of the premises will take place on Tuesday, September 4th, at 23, Regency-street, Westminster, S.W. (unless previously disposed of by private contract), and the plant and machinery will be sold on Tuesday, Wednesday, and Thursday, September 4th, 5th, and 6th, at the same address at 11:30 a.m. Some further particulars are given in our advertisement columns, and all information can be obtained of the auctioneers, 11, Billiter-square, E.C.

VACANT APPOINTMENTS.—The Corporation of Dewsbury require a properly qualified practical electrical engineer to take charge of the new electric lighting station and works. Further particulars will be found in our advertisement columns, and applications must be sent in not later than 9 a.m. on Friday, the 17th inst.

——— The Portsmouth Corporation require a junior assistant at the electric lighting works. The salary is £65 per annum. Applications must be sent in before the 15th inst. to Mr. E. Price, Superintendent, Electric Station, Portsmouth.

——— The Electricity Supply Company for Spain (Limited) require a thoroughly competent assistant electrical engineer at a commencing salary of £200 per annum. Some further particulars are given in our advertisement columns, and applications must be sent in to the Secretary of the Company not later than the 13th inst.

——— The Corporation of Blackburn require an engine and dynamo attendant for the Blackburn electricity works. Some particulars are given in our advertisement columns, and applications must be sent in to Mr. Robert E. Fox, Town Clerk, Town Hall, Blackburn, by the 25th inst. The Corporation also require a central station wireman, for which post applications have to be sent in to Mr. Fox by the same date.

LIQUIDATIONS.—A meeting of the Aladdin Primary Electric Battery Company (Limited) is to be held at 5, Fenchurch-street, E.C., on September 11th, at 2, to receive an account of the winding-up.

——— A compulsory order for the winding up of Barnard, Bishop and Barnards (Limited), metal workers, &c., of Norwich and London, has been made on the application of the Westfälische Actien-Gesellschaft für Bergbau Eisen.

BANKRUPTCIES.—At the Leeds Bankruptcy Court application was made to Judge Gates, Q.C., for the discharge of Edwin Moorhouse, electrician, of Leeds. The receiving order was made on October 21, 1891. "Heavy costs of litigation as to interest under his father's will, and interest on mortgages," was stated to be the cause of the failure. He commenced business in October, 1889, when he took a partnership in the firm of Mori and Co., electricians, of Leeds, and paid £600 as his share of the capital. The business was a fairly good one, and in May last a third partner, Mr. R. P. Stocks, still a minor, was taken into the firm. He introduced £850 capital. In August last year Mr. Mori retired, on condition that he was reserved the right to re-enter any time within three years, on paying a third share of the then value of the business, the firm having the use of his name for the same period. It was alleged that the business was then quite solvent. The debtor was entitled to a legacy of £3,000 under his father's will, which was payable in June, 1889, and he received £500 in advance on account; but, when time for payment arrived, the executors stated that the legacies could not be paid in full, and the debtor declined to abate, he having borrowed £650 on security of the legacy. Mr. Moorhouse is now in the employ of a local electrical engineer at a salary of about £150 per annum. Ultimately, the certificate was suspended for two years.

——— A receiving order has been issued in the estate of Arthur Shippey, electrical engineer, of 13, King-street, Cheapside, E.C.

——— William J. S. Green, electrician, 86, Lozells, Aston, near Birmingham, has filed a deed of arrangement with his creditors, the unsecured liabilities being given as £182. 18s. 10d., and the estimated net assets £115. 15s.

DOULTON'S STONEWARE CONDUIT.—In addition to Edinburgh and Sunderland, where large quantities of this conduit have been laid, the arc-lighting mains at Chelmsford, which were originally carried overhead, are now all placed in conduits and the old poles removed. Doulton's conduit is of comparatively recent introduction, but already upwards of 72 miles of "ways" have been laid.

WESTON ELECTRICAL INSTRUMENTS.—Messrs. Elliott Brothers inform us that they have taken over the sole supply for Great Britain and the colonies, of all the instruments for electrical measurements manufactured by the Weston Electrical Instrument Company of Newark, New Jersey. The designs of Mr. Weston for central station and laboratory standard instruments are already well known and duly appreciated for their reliability. In the United States these instruments are now almost exclusively used. As an example it may be stated that the switchboard of the largest Edison station in New York is being fitted with 127 instruments of the Weston type.

MR. J. A. EDMONDSON.—In reference to a Note appearing in our last issue, Mr. J. A. Edmondson desires us to state that the dynamos used at the Huddersfield Co-operative Society's installation were of the Edmondson type, and not as stated. The whole of the plant, with the exception of the engine, being supplied by Mr. Edmondson. This firm has in hand several important installations—one at Dewsbury for Messrs. Newsome, West and Co. (Limited) for 600 lights, and others at London, Bradford, and Barnsley.

MEDICAL BATTERY COMPANY, LIMITED (in liquidation).—The creditor members of the Committee of Inspection of this Company are congratulating themselves and the shareholders generally at the scheme sanctioned by the High Court for the reconstruction of this Company.

SUNBEAM LAMPS.—The Sunbeam Lamp Company have just issued a new price list of large and small "Sunbeam" incandescents, lamp-holders, shades, &c. The list can be obtained on application to the Secretary of the Company, Park-road, Gateshead-on-Tyne.

THE "VENLOO" INCANDESCENT LAMP.—We are informed that Messrs. E. Goossens, Pope and Co., of Venloo, Holland, have appointed Messrs. Pope and Boddy, of 26, Pall-mall, Liverpool, sole agents in the United Kingdom for the sale of Venloo lamps. In *The Electrician* of November 25, 1892, Mr. Clarence P. Feldmann, in an article entitled "Life and Efficiency Tests of Incandescent Lamps" points out the characteristic feature of these lamps, for which a considerable demand has arisen.

"ENGINEERING MAGAZINE."—The August number of this well-known magazine is now ready, and fully maintains its reputation as the best of the engineering monthlies. The contents include: "Our Enormous Annual Loss by Fire," "The Battle-Ship as a Fighting Machine" (by Mr. George W. Melville, Engineer-in-Chief of the United States Navy), "Colorado's New Gold Camps" (illustrated), "The Early Life of Great Inventors," "The Prevailing Jealousy of Wealth: Should Fortunes be Limited by Law?" "The Chicago Drainage-Channel and Waterway" (illustrated), "Electricity Direct from Coal" (by Dr. William Ostwald), "Electric Welding and Metal Working" (by Mr. Hermann Lemp, illustrated), "Beginnings and Future of the Arc Lamp" (by Mr. S. M. Hamill, illustrated), "Theatre-Building for American Cities" (illustrated); and the usual Editorial Departments on Electricity, Railways, Architecture, &c. *The Engineering Magazine* is sent post free for 1s. 3d. per copy, the annual subscription being 12s. 6d. Orders should be sent to the Publisher, *The Electrician* Office, Salisbury-court, Fleet-street, E.C.

"FIRST AID."—We have received the first number of a new monthly journal entitled *First Aid*. It is devoted to ambulance work, a subject worthy of more notice from employers of labour in factories, &c., than it at present receives.

INCOME TAX.—The Income Tax Adjustment Agency reminds the public (our readers amongst the number) that they should be more than ordinarily careful to ascertain beyond doubt whether they have been over assessed. The Agency points out that many whose incomes are not £500 will overlook the fact that they are entitled to abatement as to £160, instead of the £120 as hitherto. A point is also made of the fact that many hundreds of people pay income-tax upon incomes derived from investments where the tax has already been deducted. These persons are entitled to a readjustment of the tax, and it is not yet too late to recover income-tax over paid in respect of the last three years ended April 5, 1894.

TRADE MARKS.—It is said that the British Ambassador at Berlin has forwarded to the Foreign Office a translation of the new German law for the protection of merchandise marks, and the document has been issued as a Parliamentary paper.

POSTCARDS.—The Postmaster-General has submitted to the Treasury a scheme under which the public will be permitted to send through the post private correspondence cards with a halfpenny adhesive stamp attached, instead of being compelled to purchase the postcards now issued by the Department. We understand that this concession is largely due to the action of Mr. Henniker Heaton.

COOKING BY ELECTRICITY.—Satisfactory proof of the rapid advance in public favour of cooking by electricity is evidenced by the fact that many restaurateurs in London and elsewhere are installing electric cooking apparatus throughout their culinary departments. In many cases the electric apparatus is only used as an auxiliary to gas or coal fires, but in several instances the electric

Digitized by Google

system has entirely superseded coal or gas. At the Imperial Restaurant, a large building in Queen Victoria-street, near the Mansion House, London, cooking is entirely effected by electricity, and Mr. Percival, the proprietor, issues the following notice: "Although electricity has been publicly demonstrated to be capable of use for the generation of heat for culinary purposes, and although its advantages of freedom from dirt, dust, odour, or vitiated atmosphere is fully proved, I claim to be the first in Europe to entirely adopt the system, which not only insures cleanliness, but at the same time places at the disposal of the *chef* a means of absolutely controlling the temperature to suit the requirements of particular dishes. Visitors are invited to inspect the electrical arrangements at any time, except during the busy luncheon hours."

SECONDARY EDUCATION.—The Royal Commission on Secondary Education have adjourned their sittings to October 2nd, when they will be resumed, and continued until about the middle of September. It is considered probable that the inquiry will conclude about Whitsuntide, 1895. The report of the Commission is looked forward to with much interest by educationalists throughout the country, and is expected to result in a comprehensive measure for the advancement of technical education.

THE DUNMOW FLITCH.—Those of our readers who are acquainted with Mr. Angelo Fahie, of Monkstown, Dublin, will congratulate him upon his success in obtaining the historic flitch, which is awarded "to the couple whose lives have been most distinguished by domestic happiness" for the period of one year and a day previous to the gathering at Dunmow, Essex, which took place on Monday last.

ABERDEEN.—The Royal Lunatic Asylum is undergoing extensive alterations, involving the reconstruction of the old buildings and the erection of a new hospital. When completed, the electric light is to be adopted throughout the premises, in which plant will be erected. Messrs. New and Mayne have obtained the contract for wiring the new building to the plans and specifications of Dr. R. Mullineux Walmsley, consulting engineer to the Asylum authorities.

ABERGAVENNY.—Mr. E. Manville has presented his report to the Improvement Commissioners on the lighting of the town by electricity, and the report has been adopted.

ALDERLEY EDGE.—The Local Board have decided to apply for a Provisional Order for supplying electric current within this district. This step has been taken, it is stated, in order to forestal the application of a private company.

ASHFORD.—The Lighting Committee have met and discussed the subject of introducing the electric light. It was finally decided that no steps be taken at present.

ASTON.—It has been decided to put down additional power plant at the public baths, and an engine is to be provided for use in lighting the institution, which is now dependent on the pumping engines for power. The engine is to be provided by Messrs. Fowler, Lancaster and Co. (Limited) at a cost of about £100.

BELFAST.—The Electrical Committee of the City Council report that the various contractors for the electric lighting works are proceeding to the completion of their contracts, which it is anticipated will all be perfected within the specified time. The question of the introduction of the electric light into the reading room of the reference library was also under discussion at the last meeting, and the opinion was generally expressed that a great improvement would be effected could the light be introduced in place of gas. Councillor Henderson said the Library Committee would introduce the light if it were financially possible, but they were very much in debt.

BOWNESS.—Pending a satisfactory arrangement with the Windermere Electric Light and Power Company, it has been decided by the Local Board to withhold their sanction to the application for a Provisional Order.

BRIDLINGTON QUAY.—The sea front has now been completely lighted by electricity, and the town is to be congratulated on the success attained. The plant is in good working order, and the Building and Lighting Committee of the Town Council consider the money has been well spent. The lighting of the town by gas is in a very unsatisfactory state, but the Committee hope to be in a position to make more satisfactory arrangements next year. Mr. Brown, the Council's electrical engineer, has been publicly congratulated upon the success of his efforts in carrying out the installation on the quay.

CHURCH LIGHTING.—The work carried out by Messrs. Laing, Wharton, and Down at the Leeds parish church is now complete, and on Sunday evening last about 250 incandescents illumined the sacred edifice. The change from gas was much appreciated by the congregation.——The church of St. Martin-on-the-Hill, Scarborough, has been lighted throughout by electricity, the lamps, about 100 in number, being distributed in three-light clusters. The work has been successfully carried out by Messrs. Walker and Hutton.

COUNTRY HOUSE LIGHTING.—Philiphaugh, the historic residence of Mr. Strang Steel, near Kelso, is now lighted by electricity, power being obtained from Philiphaugh Burn. The current is used for lighting, heating, and supplying power to machines for household and other purposes. About 450 lamps are included in the installation, the work for which has been carried out by Messrs. Mavor and Coulson.

COVENTRY.—The City Council have received a letter from the Electric and General Contract Corporation asking for the appointment of a sub-committee for the purpose of settling with the engineers of the Corporation the question of the tramways at Grey Friars' Green. It was ordered that the matter be referred to the Improvement Sub-Committee, with instructions that the Corporation's engineers should report the result of the conference to the Council.

DARLINGTON.—At last week's meeting of the Town Council, in moving the adoption of the Gas Works Committee's report, Mr. Barron referred to the large consumption of gas, and the probable necessity of enlarging of the works. He considered this enlargement could be obviated by the Council deciding to introduce the electric light, to which suggestion the Gas Works Committee offered no objection. The matter is to be considered at a future meeting.

DUNDEE.—In connection with the increased demand for electric light it has been resolved by the Gas Commission that a new storage battery set be provided at an estimated cost of from £1,000 to £1,500, and tenders are to be advertised for. The Commissioners have entered into an agreement with the E. P. S. Company for the upkeep of the storage battery for five years at an annual charge of £76.

ELECTRICITY IN THE EAST.—There is a proposal to light Kwala Lumpur, Selangor, Straits Settlements, by electricity, water power being obtainable about seven miles distant.

EMBEZZLEMENT.—John Alexander, aged 32, labourer, was charged before Mr. Newton, at Marlborough-street, London, with embezzling the sum of £4, the moneys of his employers, the Electrical Company (Limited). The evidence showed that the prisoner was in December last sent by his firm to receive the sum in question and absconded with it. He afterwards voluntarily surrendered to the police at Mansfield, Notts., and confessed his guilt. One month's imprisonment.

EWELL (SURREY).—The Local Board of this district were up to June the owners of an Electric Lighting Provisional Order. This has now expired, and the Board, while desirous of taking no active steps themselves, are anxious that the Board of Trade should not entertain any application made for lighting the district by electricity by outsiders.

FOLKESTONE.—It will be remembered that at the time the Folkestone Corporation decided not to proceed with their electric lighting scheme, which had previously received the assent of the Corporation, Mr. Baker, a prominent citizen, upon whose initiative the Council were induced to negative their scheme, promised to produce a new plan by which the town could be supplied with electric current at a total cost of about £12,000, as against the original estimated outlay of £35,000. So far Mr. Baker's scheme has not been forthcoming, notwithstanding several promises from that gentleman. At the last meeting of the Corporation, when the scheme was to have been discussed, Mr. Baker was not present. It has, therefore, been decided that the discarded scheme and that prepared by Mr. Baker (if it is ready) shall be discussed at the next Council meeting. It is more than likely that the Corporation's original scheme will, with certain modifications, be ultimately adopted.

HULL.—After careful consideration, the Electric Lighting Committee have decided to recommend the Council to sanction the purchase of the additional plant stated by the Corporation's electrical engineer to be necessary to meet the forthcoming winter's demand for electric current, at a cost not to exceed £2,800.

KINGSTON-ON-THAMES.—A pleasing incident took place at the last meeting of the Corporation, when the members presented Mr. J. E. Edgcome, electrical and mechanical engineer, with a silver salver on the occasion of his marriage, as a mark of their esteem and confidence.

LONDON GAS CHARGES.—The movement recently set on foot by members of the London Vestries to call a conference of London local authorities to discuss the question of the unequal charges made by the various London gas companies is gaining ground, and in September next an important gathering is likely to meet for the purpose of considering the question of obtaining a uniform rate in the price charged for gas throughout the metropolis. The movement appears already to have partly effected its purpose, the Gas Light and Coke Company, which is the largest of the London companies, and whose district is north of the Thames, having notified

Digitized by Google

its intention of reducing the price of gas 2d. per 1,000ft. from the close of the current quarter. The price of the gas supplied by this Company will still remain 15 per cent. higher than the principal company in the southern district. An important deputation waited upon Mr. Bryce, President of the Board of Trade, yesterday, on this subject, when representatives from the Vestries of St. Luke's, Kensington, Clerkenwell, Chelsea, Hackney, Hammersmith, St. James, Westminster, Paddington, Islington, Shoreditch, Bethnal Green, and the Holborn Board of Works, were present, accompanied by a large number of Metropolitan Members of Parliament. The deputation pointed out that their object was to secure a Parliamentary enquiry in respect of all the gas companies in the metropolis, including Brentford, so far as these companies served the district, represented by the London County Council. Having heard the deputation, Mr. Bryce said that in addition he had received many memorials and resolutions passed by local authorities making a number of suggestions which were, however, so varied that they presented serious difficulty to the Board of Trade. In dealing with this question some asked for a Parliamentary inquiry and others for a Board of Trade inquiry. In the case of a Parliamentary inquiry they would be able to consider the question of the unification of the companies, and their acquisition by public authority. This plan had been carried out in nine of our great towns, in each case with satisfactory results. It was, however, a very large question, and they could not separate from it the terms which would have to be made with existing shareholders. At the time when the Parliamentary bargain with the gas companies was made, he was free to confess he thought it was a very bad bargain. If the Board of Trade had had their way a much better arrangement for the people of London would have been come to. They had, however, learnt something by experience, and had taken care in the case of the recent Electric Lighting Acts to safeguard the interests of the public. If legislation was desired it was quite clear that Parliament would not be satisfied with anything else than a Parliamentary enquiry as preliminary to such legislation.

Newcastle-on-Tyne.—The special committee appointed to report upon the proposed lighting of the City by electricity under the Corporation scheme have decided to obtain the opinion of Prof. A. B. W. Kennedy, and to arrange for him to visit the City and report to the Council. The Local Gas Company have sent in a bill for £600 for the lamps which have been extinguished by the electric lights now in use, the Company contending that once a lamp is ordered, it cannot be dispensed with except by agreement with the Company.

Rugby School.—The Rugby School Electric Lighting Company are putting down additional motive power by replacing the 100-h.p. tandem gas engines at the electric lighting station with a new one of the same type, but of 120 h.p.

Salford.—It is announced that the lighting works will be complete in time for the winter supply. The price at which the public are to be supplied has not yet been decided upon.

Salisbury.—The Town Council have engaged the services of Mr. Robert Hammond to advise them in connection with the licence applied for by the Salisbury Electric Light and Supply Company at an inclusive fee of £50. Mr. Hammond has prepared a report which was to be submitted to the council yesterday (Thursday).

Shoreditch (London).—The Electric Lighting Order obtained by the Vestry expires this year, and the Board of Trade have intimated, in reply to the Vestry's request, that they will consider it in force for another year, to enable the Vestry to carry out their electric lighting scheme.

Southend-on-Sea.—The Marine Park and Gardens just opened, which comprise about 15 acres of ground on the Beaumont estate, and to which there is a direct approach from the sea front, is lighted by electricity.

South Shields.—At the last meeting of the Corporation the deputation, consisting of the Mayor, Aldermen Rennoldson and Eltringham, the Electrical Engineer (Mr. J. A. Jeckell), and the Town Clerk, who were appointed some time back to visit some of the principal electric lighting stations in the leading provincial towns, reported that they had visited Huddersfield, Derby, Burton-on-Trent, Bristol, and Oxford, and had inspected the central stations there. A description of the various works which had been visited was presented to the Electric Lighting Committee, and this contained recommendations as to the type of boilers, engines, and dynamos to be used. It was resolved: (1) That the marine type of boiler and the vertical type of engine, compound or triple expansion, with surface condensers to each, and direct coupled, if practicable at a moderate speed, as recommended by the deputation, be adopted; and (2) that the scheme of high and low tension mains, as shown on the plans submitted by the Electrical Engineer, be approved, and that he be instructed to prepare specifications in accordance with them.

Stockton.—The Town Clerk has communicated to the Board of Trade, requesting an extension of the Electric Lighting Order granted to the Council in 1890. After discussion it was decided that the Corporation were prepared to give effect to the provisions of the Order within two years.

St. Pancras (London).—At their last meeting the Electricity Committee reported that in consequence of the demand for current in the district north of the Cobden sub-stations having exceeded that contemplated when the mains were originally put down, it was necessary that supplementary feeders and mains should be laid to augment those already put down. It was essential that this work be carried out at once, so that it may be completed and ready for the coming winter demand. The cost would amount to about £2,800. The Committee recommended that the sanction of the Vestry be given to this outlay, so that the work might be done at once. It was stated that if the extension were not carried out the department would be in a difficulty during the ensuing winter. When the King's-road station was completed the Committee would have a further report to make. Prof. Robinson has consented to a reduction of his commission for this extension. He will now receive ½ per cent. for drawing the plans, and 2 per cent. for superintending the laying of the mains; thus receiving 2½ per cent. instead of 4 per cent., or a saving of 1½ per cent. on the outlay. The Committee have plans for laying mains for the whole of the parish; but, so far as North St. Pancras is concerned, will have to wait until the King's-road station is complete. The Committee's recommendations were unanimously adopted.

Theatre Lighting.—The Coliseum at Oldham is now lighted by electricity, upwards of 300 incandescents and 3 arcs being used. The work has been carried out under the supervision of Mr. G. St. John Day. Mr. Day has used a wood casing and covering of his own design.——The Tyne Theatre, Newcastle-upon-Tyne, has recently undergone redecoration and refurnishing. Included in the improvements is the adopiton of the electric light throughout the building.

The Transvaal.—Some time back a suggestion was made by Major Leaver to utilise electric power for supplying various batteries in the Rand district with current. A scheme approximating to the Major's idea was prepared by Messrs. Siemens and Halske, who proposed to erect a central station at Brakpan, in the neighbourhood of the gold mines. This scheme was estimated to cost about £275,000, and the capital has been obtained, a portion in the Rand district and a portion at Berlin. A concession has been granted for carrying this scheme into effect. Another scheme, upon a much more extensive scale, and estimated to require a capital of about £700,000, has been prepared by Mr. R. Lewis Cousens, M.I.C.E., electrical engineer, of Johannesburg, who proposes to obtain the necessary power from the river Vaal. This would necessitate the cutting of a canal five miles in length, and would secure an effective fall of 100ft. for turbine purposes. The current would be conveyed to the mines over about 40 miles of cable, and be equal to about 20,000 effective horse-power, which would provide for all emergencies, or probable extensions. The position of the generating station is to be on the Farm Vishgat, close to Engelbrecht's Drift. It is claimed for this scheme that it will almost entirely do away with the necessity for the use of steam engines. Mr. Cousens' plan has not been made the subject of a concession, but negotiations with the Government have been going on for the purpose of obtaining the necessary permission for the erection of poles to carry the cable. The plans prepared by Mr. Cousens have received the approval of the executive. The whole of the surveys have been completed, and it is ultimately intended to erect 10 turbines, 3 being at first installed, and the remainder as demand arises. It is proposed to charge about ⅜d. per i.h.p. per hour, and this is calculated to be about the cost at the present time to companies using economical engines. The scheme appears to meet with the warm approval of those more immediately concerned, and Mr. Cousens is to be congratulated on the success of his endeavours to bring his scheme to maturity, and upon his success in obtaining the grant from the Government to proceed with the undertaking.

Waterloo and City Railway.—The Chairman at the meeting yesterday of the shareholders of this Company, was able to announce that in response to the application for capital the shares were over applied for to the extent of 20,000, and the stock still remains at a premium. He was futher able to announce that no calls will be required—at any rate for this year. A full report of the proceedings, which were purely formal, will be found elsewhere.

Winchester.—The City Council have decided to adopt the report of the Joint General Purposes and Electric Lighting Committees, under which application is to be made for a Provisional Order at a cost of about £250. A scheme is before the Council from the Brush Company, which will ultimately doubtless receive its support.

Digitized by Google

WORCESTER.—The Watch Committee of the Corporation announce that Mr. Preece, their consulting engineer, and the Brush Company, the contractors for the work, have fixed October 11th as the date for the opening ceremony of the electric lighting station. The Guildhall and Public Hall and the street lamps will then be ready for lighting, and the Electrical Exhibition will be ready for opening.

WREXHAM.—In reference to the proposal of the Wrexham Town Council to effect a transfer of the Provisional Order granted to the local electric lighting company, a letter has been received from the Board of Trade pointing out that, "as the undertakers have not constructed any works under the Order they do not appear to possess any undertaking which, in the opinion of the Board of Trade, could properly be purchased by the Corporation." If, therefore, the Corporation desire to obtain statutory powers to supply electrical energy within the district, the Board of Trade are prepared to consider the expediency of revoking the Company's Order and granting a fresh one to the Corporation. The negotiations between the Company and the Corporation are apparently at an end.

YARMOUTH.—In addition to the lighting of the School of Art for the Technical Education Committee of the Yarmouth Corporation, Messrs. Crampton and Co., of Cambridge, are putting in the light at the Cromwell Hotel, Yarmouth.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

11,418. KINGSBURY (Western Electric Company). Telephone transmitters.

COMPANIES' MEETINGS AND REPORTS.

United River Plate Telephone Company (Limited).

The eighth ordinary general meeting of this Company was held on Friday at Winchester House under the presidency of Mr. J. Irving Courtenay (Chairman).

The SECRETARY (Mr. Robert Herring) read the notice convening the meeting.

The CHAIRMAN said: In reviewing the operations of the past year in the River Plate, it is satisfactory to note that the business of the Company has shown a decided improvement over that of the preceding year. We have gone through another very trying period of disturbance—political and monetary—and, though we cannot but feel disappointed that our efforts have been to a large extent neutralised by the unexpected rise in the gold premium, still it is a matter for congratulation that the receipts have continually increased, and also their net value for the year. It might reasonably have been expected that the number of subscribers would have fallen off as a consequence of the depressed condition of commercial affairs in the Plate; but, on the contrary, there has been during the year an increase of 606, for though there have been many withdrawals, the number of new subscribers has always exceeded those withdrawn, and upon this Mr. Krabbe (our local Director), who was present at our meeting last year, and addressed you, remarks: "Considering the very bad position of a large part of business in Buenos Ayres, which has been to a great extent the result, in the first place, of over-speculation in imports, and in the second place, of the very serious drought that the country has been experiencing for some seasons, the increase in subscribers must be considered extremely satisfactory, and shows that all through the crisis there is a natural increase, though small, in the total of business in Buenos Ayres—a healthy promise for the future. Of course this is to a certain extent the result of the *necessity* that the telephone is becoming; but we have other signs, such as tramway passengers, which also show an increase, and prove that it is resulting from increase of business in the city." The receipts at par of exchange are £134,053, being an increase of £18,711 over the previous year. I indicated when I last addressed you that you might expect some increase in the working expenses. The working expenses for the past year at par of exchange are £60,874, as compared with £57,669, and the percentage is 45·41 per cent., as against 49·99 per cent. in 1893, which testifies to the economical management in the Plate, where economies have been made in every possible direction; but we have had to increase the salaries of our employés, and the full effect of these additional charges has yet to be felt. In the Construction Department at Buenos Ayres, the work has been unusually heavy owing to the changes for new buildings, and this is likely to continue. We have had to make a number of lines for new subscribers while changing and altering our way-leaves in various parts of the city. The municipality is advancing rapidly with the new Avenida, which will necessitate a considerable outlay in getting across it with our lines. Our manager (Mr. Chappell) reports that the service continues good, and the complaints from subscribers have been very few. I sometimes think that shareholders hardly realise the difficulty there is in maintaining a good service during such revolutionary outbreaks as occurred last year, and the risks the staff of the Company have to run when a central station becomes an important strategical position, as was the case with ours last year. The manager and staff deserve much credit for the energy and pluck they have displayed in the interests of the Company. I now come to the most serious point of all, namely, the loss on exchange. As you are aware this is a matter over which we have no control whatever. The loss on exchange is enormous, and for the year under review amounts to £54,124. 17s. 9d., the highest figure yet reached. The fluctuations in the gold premium are so frequent and rapid that I do not wish to offer an opinion as to what its course may be in the future. So far as the past year is concerned, the loss on exchange swallows up the larger part of the profit that otherwise would be available for distribution among our shareholders. The net profit, after paying the Debenture interest and all other charges, is £9,782, and I repeat that it is most gratifying and encouraging—amid the turmoil and distress that has prevailed throughout the Argentine Republic, in common, mark you, with almost any other part of the world you can name—to be able to record this result. It is, indeed, full

Digitized by Google

of hope for us. As mentioned in the report, we have allocated to certain accounts the sum of £4,270, of which the principal item is a sum of £3,000 transferred to depreciation and renewal fund. The net balance to be carried forward to next year will then stand at £6,417. 17s. 4d. Upon this review of the situation, there can, surely, be no doubt as to what should be the policy of the Directors, and that is to husband the cash resources of the Company and to strengthen its financial position as best they can. I feel certain that we shall have your support in giving practical effect to this policy. I now move—

"*That the report and accounts submitted to this meeting be, and they are, hereby received and adopted by the Company.*"

Mr. FRANK W. JONES, in seconding the motion, said their staff on the other side had passed through trying times since they last met. One instance would suffice to show what dangers they had been exposed to. During the late rebellion the Company's central office at Rosario, which stood rather high, was occupied by troops more or less as a fortress, and five men were killed in the building. He was thankful to say that none of their men were killed, although one or two were seriously injured.

The report was then adopted.

Mr. F. GREEN proposed the re-election of the retiring Directors—the Chairman and Mr. George Cooper. He said he had worked with both gentlemen now some years, and he could assure the shareholders that they devoted themselves to the interests of the Company.

Mr. G. DAVEY TURNER seconded the proposition, and it was agreed to unanimously.

The CHAIRMAN: I thank you on behalf of Mr. Cooper and myself for re-electing us. Mr. Cooper is well known in the City of London and in Argentina. He is now in the River Plate, and no doubt he will assist our officers and advisers there in doing their best for the shareholders.

Mr. A. O. CHUDLEIGH moved the re-appointment of the auditors Messrs. Cooper Brothers and Co., at a fee of 25 guineas.

Mr. J. R. BAILLIE seconded the motion, which was adopted.

Mr. FRANK W. JONES then proposed

"*That the thanks of the meeting be given to the General Manager in the River Plate, Mr. Chappell, the Buenos Ayres Manager, Mr. Parker, and their general staff; also to the local consulting Directors, Messrs. Fels and Krabbe, for the ability and zeal with which the business of the Company in the River Plate has been conducted during the past year.*"

Mr. J. R. BAILLIE said he was in Buenos Ayres last year, and had the pleasure of meeting Mr. Krabbe and Mr. Chappell, and from what he saw there he had pleasure in seconding the proposal.

The resolution was then carried unanimously.

The CHAIRMAN: I am glad to find that amongst those present we have a shareholder who has been out there and seen these gentlemen face to face. What he says only confirms all we have heard. Mr. Jones will communicate your vote of thanks to the proper quarter.

The proceedings then terminated.

Crompton and Co. (Limited).

The following is the text of the sixth report of the Directors of this Company, which is to be presented at the annual general meeting of shareholders, to be held at the Cannon-street Hotel, E.C., on Monday next, the 13th inst., at three o'clock:—

For the period under review (the year to March 31st last) the amount of the Company's business has satisfactorily increased, but the net profits, in consequence of close competition, show a reduction as compared with last year, and this, notwithstanding the fact that the Directors by careful management have reduced the expenses in many departments. The net profits for the year amount to £11,741. 2s. 7d., and after providing for debenture interest, and the payments set out in the revenue accounts, there remains a balance of £6,116. 3s. 5d., out of which the Directors propose to set aside £1,000 for contingencies and doubtful debts, to pay a dividend of 3s. per share on the Preference shares, and to carry forward the balance. The Directors regret that the net profits are insufficient to allow for the full dividend on the Preference shares; at the same time they do not think there is anything discouraging as to the future of the Company. The works are in first-rate order and condition, and under the new management the cost price of manufacture has been considerably reduced, while the various departments outside the works are at the same time being carefully reorganised with the view of reducing expenditure to the utmost without affecting their efficiency.

Since April, 1891, the Directors have entered into no contracts whatever under which the payments for work done were to be partly made in shares or securities, but they feel that the value of some of the securities previously taken as part payment may be considered doubtful. Recognising the necessity of reducing such doubtful assets or securities to their proper value in the Company's books, they propose that an amount of £20,000 shall be written off, and to enable this to be done they have obtained the assent of the two Managing Directors, Messrs. Crompton and Albright to relinquish an equal amount of Ordinary shares. The effect of this transaction will not be to deprive the Company of any value which the securities in question may hereafter attain, and the reduction of the amount of Ordinary shares must be for the benefit of the members generally.

The Directors are glad to be able to report that the cooking and heating department of the Company, which has been practically established during the past year, is likely, in their opinion, to prove a very valuable addition to the Company's business.

In response to their circulars in January last with regard to the proposed issue of £100,000 of Four and a-Half per Cent. Debentures, the Directors have received promises from the debenture and shareholders of the Company to subscribe for the new issue to the amount of nearly £32,000; but as this support was insufficient to enable the issue to be made with any certainty, the Board considered it better to wait for the statement of accounts now presented. It is intended to take further steps to place the debentures during the ensuing autumn; but they wish to urge upon the shareholders that it is in their own interests to assist in this issue, which is of such great importance to the Company. At the same time, they would remind the shareholders that the security for these debentures is undoubted. The property of the Company, even after the reductions before referred to, amounts to £236,618, including uncalled capital, but without reckoning the value of patents and goodwill, and the income of the Company for the last six years has averaged £11,839 per annum, while the interest required for the total proposed issue of debentures would only amount to £4,500 per annum.

The Chairman (Viscount Emlyn) retires by rotation, but offers himself for re-election; and the auditors (Messrs. J. H. Duncan and Co.) also offer themselves for re-election.

An extraordinary general meeting of the shareholders of the Company will be held at 3:30 p.m., or so soon as the business of the above ordinary general meeting is concluded, for the purpose of considering, and, if approved, of passing, the following special resolution:—

"*That the capital of the Company be reduced from £300,000 to £280,000 by cancelling paid-up capital which has been lost, or is unrepresented by available assets, to the extent of £20,000, by cancelling 4,000 Ordinary fully paid-up shares of the Company, numbered 2,785 to 6,784 inclusive, which have been issued.*"

Waterloo and City Railway Company.

The first half-yearly general meeting of this Company was held on Thursday at Waterloo Station, Mr. W. S. Portal (Chairman) presiding.

The Secretary (Mr. Fred. J. Macaulay) read the notice convening the meeting.

The CHAIRMAN, after affixing the seal of the Company to the register of shareholders, in the course of which he observed that the shareholders numbered 475, said: This being the first half-yearly meeting, there is very little for me to say, but that little is of a hopeful nature, and I trust that at each succeeding meeting, whoever has the honour of presiding may have a good account to give of the proceedings in connection with the Company. As you are aware the prospectus has been issued, and I may inform you that as a response 2,000 shares were applied for in excess of what were required. The stock has been from the first at a premium, and still remains so. The construction of the main portion of the line has been given on tender, at less than the Parliamentary estimates, to the responsible firm of Messrs. Mowlem, Burt and Co. One of the cylinders, which is 12ft. in diameter, is now laying in the contractor's yard, and is rather an exceptional sight. The engineer reports that the borings are on the whole satisfactory, and already staging has been prepared in the river close to Blackfriars Bridge. I have been asked to say if any calls will be made, and my reply is that no calls will be required, at all events this year. That part of the line which has been entrusted to Messrs. Mowlem, Burt and Co. will be finished, it is expected, in two and a-half years. The terminal stations in the City and here at Waterloo are still under consideration, and will form the subject of separate contracts. With regard to the question of the Forged Transfers Acts, mentioned in the report, we recommend you to adopt these Acts, as all the railway companies except one have done. I may add that we do not intend to make any charge to the registered shareholders. All the necessary consents from the several public bodies have been obtained, and up to the present time no obstacles have been encountered by the engineers, and everything is making satisfactory progress. I can only hope that if I am spared to meet you another year I shall be able to give you a good account of what has taken place. I will now move that the report and statement of accounts be adopted.

Lieut.-Col. Hon. H. W. CAMPBELL (Deputy-Chairman) seconded the motion, which was adopted unanimously.

The CHAIRMAN then proposed—

"*That the Directors be and they are hereby authorised to exercise, in respect of transfers now or hereafter entered in the books of the Company, the powers given by the Forged Transfers Acts, 1891 and 1892, to make compensation for any loss arising from a transfer of any shares in pursuance of a forged transfer or of a transfer under a forged power of attorney.*"

Lieut.-Col. Hon. H. W. CAMPBELL seconded the resolution, which was carried, and the meeting terminated.

Birmingham Central Tramways Company (Limited).

The report of the Directors of this Company, which will be submitted at the meeting to be held at the "Queen's Head Hotel," Stephenson-place, Birmingham, on Wednesday next, at 12:30 o'clock, states that the working profit for the past year, omitting the Corporation charges for maintenance, amounts to £52,804. 8s. 11d., as compared with £50,424. 1s. 10d. for the year ended June 30, 1893, showing an improvement of £2,380. 7s. 1d. The Corporation charges for maintenance, however, have again advanced by the sum of £1,729. 14s. 11d., which reduces the net comparative increase of working profit to £650. 12s. 2d. The revenue account shows a balance of £24,978. 3s. 5d., to which has to be added the sum of £3,438

Digitized by Google

6s. 9d. brought forward from last year's account, making altogether £28,416. 10s. 2d. The Directors propose to divide this sum as follows :— £10,000 to reserve account against depreciation ; the payment of the 5 per cent. guaranteed dividend, amounting to £5,000 ; a dividend of 2½ per cent. upon the Ordinary shares (amounting to £9,700) for the year ending June 30th, payable September 1st next ; and £3,716. 10s. 2d. to be carried forward.

The Directors state that the position of the Company is one of assured and increasing strength and security ; but impress upon the shareholders the wisdom of dealing boldly and speedily with certain items of capital expenditure, which are not now fairly represented by assets of the Company, and to which reference is made in the auditors' report.

Mr. Martyn J. Smith has retired from the Board, and Mr. John Booth and Mr. Ebbsmith now retire by rotation, and offer themselves for reelection ; as do Messrs. Howard Smith, Slocombe and Co., auditors.

The working of the Electric Department of the Company's system is shown below :—

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "The Electrician" Electrical Trades' Directory and Handbook, 1894, pages 274-300, *&c., &c.*]

LEA, HOHRSTADT AND CO. (LIMITED).—This Company was registered on August 1st with a capital of £10,000, in £10 shares, to carry on the business of fancy brass manufacturers, stampers and piercers, electroplaters, engineers' tool makers, engineers, &c., at Birmingham, or elsewhere.

ELECTRIC LIGHTING AND GENERAL DEVELOPMENT SYNDICATE (LIMITED).—The annual returns of this Company, made up to August 8, 1893, and June 5, 1894, were both recently filed. Out of a nominal capital of £700, in £10 shares, 48 have been taken up, and of these 20 were issued as fully paid. Upon the remaining 28 shares the full amount has been called and paid.

ELECTRO-CHEMICAL COMPANY (LIMITED).—The annual return of this Company, made up to June 26, 1894, has been filed. Out of a nominal capital of £200,000, divided into 26,000 £10 per Cent. Preference and 14,000 Ordinary shares of £10 each, 17,005 Preference and all the Ordinary shares have been taken up. Of these 5,000 of the former and all the latter have been considered as fully paid. Calls amounting to £3 per share have been made on the 12,005 Preference shares, resulting in the payment of £35,548, and leaving £467 in arrears.

ELECTRIC TIME DISTRIBUTING AND CLOCK COMPANY (LIMITED).—The annual return of this Company, made up to June 26, 1894, has been filed. Out of a nominal capital of £5,000, in £1 shares, 2,084 shares have been taken up. Of these, 2,000 were issued as fully paid. Upon 82 shares the full amount has been called, and a call of 10s. per share has been made on the remainder, resulting in the total receipt of £83.

ELECTRICITY USERS' ASSOCIATION (LIMITED).—The statutory return of this Company, made up to July 3rd, was recently filed. The capital is £2,000, in £1 shares, and 107 shares are now taken up. Consequent upon a call of £1 per share which has been made, £57 has been received, leaving £50 still to be paid.

CITY NOTES.

AMALGAMATION OF FRENCH CABLE INTERESTS.—A general meeting of the shareholders of the Compagnie Française du Télégraphe de Paris à New York is, says the *Bulletin d'Electricité et de la Télégraphie*, to be held on the 31st inst., with the object of deciding the question of its absorption into the Société Française des Télégraphes Sousmarins, whose shareholders are also to meet on the same date. The same journal, in the course of a critical review of the position of the two companies, enters fully into the relations between them and the French Government, and points out that some difficulty will be experienced in obtaining the necessary quorum of votes to bring about the proposed amalgamation.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended August 5th were £848, as against £804 in the corresponding period of 1893, being an increase of £44. The total receipts for the half-year amount to £4,306, as against £4,237 for the corresponding period of 1893, an increase of £69.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—This Company's estimated traffic receipts for the month of July amounted to £1,400, as against £1,656 in the corresponding period of last year.

GAS LIGHT AND COKE COMPANY.—At the meeting of this Company, held last week, the question of the price of gas north and south of the Thames was dealt with at some length by the Chairman, Col. W. T. Makins, to whom Mr. Livesey, the Chairman of the South Metropolitan Company, replied. Mr. Livesey contended that the excessive charges made by the Gas Light and Coke Company had brought the Gas Workers' Union into existence, and had so placed the gas companies under the control of the men's unions that the South Metropolitan Company could stand it no longer, and resolved to take independent action, with the result that everyone was benefited, including the working-man himself. Colonel Makins acknowledged the beneficial effect of Mr. Livesey's action, but, in regard to the higher price charged by the Gas Light and Coke Company for the north of the Thames district, pointed out that the southern Companies were not nearly so much affected by competition with the electric light as was the northern Company. Hitherto Col. Makins has rather derided the idea of the electric light affecting the Gas Light and Coke Company's receipts. His remarks on this occasion point to a chastened spirit. Facts are stubborn things, and having once admitted the influence of the electric light on the receipts of the great corporation over which he presides, it is not unlikely that Col. Makins will see occasion to make further reference to the subject at future meetings. The references at the meeting to the huge profits made by the metropolitan gas companies since 1887 were given at the enormous figure of £16,978,000.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for July, 1894, amount to £25,600, and from January 1st to July 31, 1894, £155,400. In the corresponding months of 1892 and 1893 the amounts were £152,000 and £156,800 respectively.

GULCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY (LIMITED) (*in liquidation*).—An extraordinary general meeting of this Company is to be held at the offices of Messrs. Kemp, Ford and Co., 73, Lombard street, E.C., on Thursday, the 16th inst., at 11 o'clock, when the resolution passed at the meeting of the Company held on the 1st inst. will be submitted for confirmation as a special resolution. The resolution is set out in our issue of July 27th, page 379.

KNIGHT AND CROWTHER (LIMITED).—The Directors propose dividends for the half-year ended June 30th, on the Preference shares of 6½ per cent., and on the Ordinary shares of 7 per cent. (making 6½ and 6 per cent. respectively for the year).

LONDON ELECTRIC SUPPLY CORPORATION (LIMITED).—With regard to the action taken by Lord Wantage in foreclosing on the Debentures held by him in this Corporation, it would appear that the shareholders were unable to pay off the Debentures when they became due, and his Lordship, therefore, to protect the concern, took possession. In addition to holding the Debentures, Lord Wantage is by far the largest shareholder (both Ordinary and Preference) in the concern, and the next largest shareholders are satisfied with his Lordship's action, and regard it as the best step to be taken under the circumstances. The Corporation's business will go on just as hitherto, and it is anticipated that Lord Wantage will be able to effect those considerable economies in the working of the business which, with a full Board of Directors, it has been found difficult to bring about. Mr. Bain, who has for many years acted as accountant and secretary to the Corporation, has been appointed receiver and manager, and still holds his position as secretary, so that no confusion is likely to arise in the various interests at stake. The action taken by Lord Wantage has not come upon the shareholders with surprise, as the difficulty of redeeming the Debentures as they became due loomed before them for some time past. The Corporation has been unfortunate, but the shareholders have been kept fully acquainted with the position of affairs. It is to be hoped, in the interest of all parties, that the altered conditions may prove the turning point in the fortunes of the Corporation.

OSWESTRY ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The Directors of this Company have arranged to guarantee a minimum dividend of 3 per cent. per annum upon the share capital called up from time to time up to £4,000, such guarantee to be in force for a period of three years from the date of the first supply of electricity to the town by the Company, but is not to apply to the shares held by the present Chairman.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have ordered £100,000 Five per Cent. Debenture Stock (in lieu of scrip) of the City of London Electric Lighting Company (Limited), to be quoted in the Official List.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ended August 3rd (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,335.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the two weeks ending July 31st were £1,754, as compared with £1,781 for the corresponding period of last year.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 848.—Vol. XXXIII. FRIDAY, AUGUST 17, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

The atmosphere of Oxford appears to have infused something of the old spirit of vigour into the recent meeting of the British Association; not only was the attendance good, but the Papers and discussions were excellent both in quantity and quality. The formation of new sections, the sub-sectioning of others, and the temporary coalescence of engineers and mathematicians, of physicist, and physiologists, have been attended with the happiest results. Not a little of the success of the Oxford meeting must, however, be attributed to the charming environment and the convenience which such a city possesses for simultaneous gatherings of moderate dimensions. Papers and discussions of every degree, from the profound to the popular, were offered, and even outsiders who could not follow the arguments must have enjoyed the human side of some of the debates. The cock-sureness of the four-figure physicist with his theories of vision could be compared with the cautiousness of the physiologist ready to dispute any cut-and-dried theory, but eager to accept any hypothesis rather than none. Good solid work was represented in brief reports on determinations of electrical resistance, and comparison of standards. A *résumé* of the leading Papers will be found elsewhere in our present issue, and here we will allude to one or two of the more popular discussions.

Confusion is often bad enough when, in scientific literature and discussions, different terms are employed for the purpose of expressing identically the same idea. But it becomes a hundred times worse confounded when to this is added the vice of using the same term to express a number of totally distinct or—what is even worse—slightly different ideas. The bulk of the speakers who took part in the discussion on Mr. Parker and Prof. S. P. Thompson's Papers, at the British Association on Monday, were guilty of the latter sin. Almost every speaker who adverted to the point which had been raised by Sir Frederick Bramwell—viz., the relative costs of gas and electric light—spoke of "the number of 8-c.p. lamps per *unit*." This led Mr. Swinburne very pertinently to put the simple question: What *is* a unit? Prof. S. P. Thompson also sinned in this respect by appropriating the word "reactance" to express the idea usually conveyed by the word "impedance." An alternating current, he said, is determined by the ratio of the electromotive force to the reactance! Now, not only have Oliver Heaviside and other mathematicians employed this word "reactance" to express only that term in the impedance expression which is due to magnetic induction, but this meaning of the word has become fairly generally adopted, and it has even been authoritatively accepted in America. Prof. Thompson's act in annexing the word to express what everyone else knows as "impedance" is therefore liable to lead to confusion.

The point which Sir Frederick Bramwell raised was one which has often been discussed, but which is incapable of exact calculation. Mr. Preece had given the easily remembered and interesting formula: "Gas at 3s. per thousand equals electricity at sixpence a unit." What Sir Frederick wanted to know, and what Mr. Preece did not appear to be able to demonstrate on the spot, was—how the interesting formula was arrived at. The performances of fish-tail and argand burners, and of hotel waiters who turn off the electric light promptly whenever it is wanted as well as whenever it is not, were somewhat vaguely discussed. But nobody seemed able to put down the actual figures, and conclusively show that the consumer who pays sixpence for his unit gets as much light as he who pays three shillings for his 1,000 cubic feet of gas. If meter rents and interest on first cost of wiring and fittings were reckoned; if the dirtiness of gas burners could be compared with the dirtiness of lamp globes; if saving of decorations and doctors' bills could be computed, and a price fixed for the convenience of being able to turn up the light whenever it is wanted, the ratio might be reduced to a rigidly arithmetical quantity. The old rule was to take sixpence a unit as equivalent to six shillings per thousand. For the last four or five years it has been safe to multiply the price of the unit by ten to give the price per thousand, and the result of careful analysis of the tests of gas burners, published in *The Electrician* in December last, justified the use of the factor 8. Unless Mr. Preece can give good reasons for using the factor 6, we should prefer to say that electric supply at sixpence is equivalent to gas at *about* three shillings per thousand.

The question which Mr. Thomas Parker put to Mr. Preece as to the efficiency of his system of "Signalling through Space" reminds us of the remark which a puzzled individual made to us at the close of the meeting. So much fuss had been made about the fact that a current started in a wire in one place will generate a current in a wire in another place

Digitized by Google

even though there is no electrical conduction from one wire to the other, that our puzzled friend—who is a very clever electrical engineer, by-the-bye—asked us to correct him if he was wrong in believing it to be a fact that a current may be started in the secondary circuit of a transformer by starting a current in the primary, even though there be no conduction between the two circuits. We said he was quite right; and then he seemed much puzzled to know why such a "to do" had been made about the occurrence of the same thing in the signalling business. Speaking of transformers, and of the efficiency of signalling by electro-magnetic waves, leads us to remark on the absurdity of trying to prove that the efficiency of signalling in this way can ever be more than a microscopic quantity. In the transformer, with its interlaced primary and secondary coils and its good iron magnetic circuit, the efficiency is indeed something to be very proud of—at full load. But, how can anything but an insignificantly small efficiency be expected when the two circuits are many miles apart, and when, instead of a few inches of good magnetic iron, there are many miles of bad magnetic air? Yet such are the conditions of Mr. PREECE's ingenious system of signalling by electromagnetic waves. Mr. PREECE, however, very skilfully turned the edge of Mr. PARKER's inquiry upon the questioner, by reminding Mr. PARKER that the big currents used in his Liverpool Overhead Railway were no end of a nuisance for miles around to telegraphic and telephonic operators.

THE justification of the running of a 3ft. flywheel at a peripheral speed of 666ft. per second by reference to an American torpedo, as is done by Mr. SWINTON in our correspondence columns, is not very sound engineering, and we cannot agree with him that such a wheel of solid steel would be safe. But Mr. SHARP has indicated one way of putting an initial compression on the rim, which would help to keep it together. It is possible, however, to provide this initial force otherwise than by tension of the arms, which ought not to have additional work thrown on them. In connection with the heavy, sudden, and short loads required for electric welding, it was proposed by Prof. G. FORBES and Mr. HALPIN, if we remember right, to make a flywheel rim of channel section, and to wind it full of steel wire under tension. This plan, which seems much less expensive than the only other alternative, namely, shrinking on a hoop, would possibly provide a safe flywheel for these extreme speeds.

THE connection between "scientific dress-making" and electrical science and engineering is not very apparent; but the action which was tried before Mr. Justice WRIGHT, and was recently taken to the Court of Appeal, may be, nevertheless, of some interest to our readers. The art of scientific dress-making consists, as we understand it, in the use of what an engineer would call a template, but which was described as a sleeve chart, "a sheet of thin cardboard in the shape of a sleeve, with various lines, scales, and figures printed on it, together with holes through which pencil-marks could be made on paper or material placed beneath it." This "chart" had been registered under the Copyright Act, and it had been held by Mr. Justice WRIGHT that it was capable of being so registered. The defendant, however, appealed, and it was contended on her behalf that the chart was not a "book, map, chart, or plan" within the meaning of the Act, that it had no literary merit, and that it would be useless and unintelligible without further explanation. Mr. Justice WRIGHT thought that a map, chart, or plan need not be topographical; but the LORD CHANCELLOR observed that the words and figures on the "chart" did not in combination convey any intelligible idea, nor could they be of the slightest use to anyone, apart from the cardboard upon which they were printed. The cardboard was, in fact, a measuring apparatus or tool, and he did not think it necessary to determine whether such an apparatus could be the subject of letters patent as an invention, though he was far from saying that it could not be so, if novel. Lord Justice LINDLEY said that the thing was in truth a measuring machine, and no more a chart than a scaled ruler. If what was published was not separately published, was not a publication complete in itself, but was only a direction on a tool or machine, to be understood and used with it, such direction could not, in his opinion, be severed from the tool or machine of which it was really part, and could not be monopolised by its inventor under the Copyright Act.

So much for copyright. We now turn to the most recent treatise on "The Law of Patents," by Mr. HENRY CUNYNGHAME, an important book which we have not yet reviewed, and find that the subject matter for a patent must be for some kind of manufacture. If extended to a new process, that only means a process resulting in an article. An art, or principle, or a new metal cannot be patented, unless in such a way as to amount to a craft or manufacture. "An invention for some mathematical process, which, however useful, was not a manufacture, could not be patented. Thus, a new method of computing logarithms, or a new cypher, or a new method of book-keeping, would not be good subjects of patents. It follows again that the author of a book cannot be said to 'manufacture' it. . . . The author would not be patenting a new craft, but only the product . . . of an art, and could in no sense term himself a manufacturer." This being so, we venture to think that there is a considerable gap between the Copyright Act and the Patent Acts, through which many valuable inventions might fall. The officials at the Copyright Office hesitated, to our knowledge, some years ago, to accept a design of a chronograph dial containing a number of computed scales, and the inventor of a certain slide rule has endeavoured to protect himself by both copyrighting and patenting his instrument. A mere template could no doubt be patented, but slide rules are old, and any new application consists in the imprinting on them of calculated scales with numbers and words. The slide rule is of course a manufacture, but the scales are the product of an art; the inventor seems here to be an author, not a manufacturer. A pocket rule might be made with quotations from Shakespeare printed on it: would this be patentable? Or with some useful formulæ, or with some useful tables arranged as curves. These, printed on paper, are obviously no subject matter for a patent. The foot rule on which they are placed cannot alter

Digitized by Google

their character. Can a slide rule on which they are engraved, or on which perhaps printed scales are pasted, materially alter the nature of the invention? At what point, then, can words, figures and scales, on slide rules and many other instruments of like nature, be rejected from Stationers' Hall and accepted at the Patent Office? The LORD CHANCELLOR did not deem it necessary for him to determine whether the sleeve chart could or could not be patented. Is it anybody's business to do so?

THE opinion which was pretty generally expressed, both at New York and Chicago, in the discussion on Mr. FARNHAM'S Paper on the "Destructive Effect of Electrical Currents on Subterranean Metal Pipes," was that the difficulties which had been experienced in the States in connection with the use of an uninsulated return for electric tramways were a thing of the past; the putting of the negative pole to earth, and of plenty of copper underground being considered a practically complete solution of the problem. Speakers, however, did not remember to point out that this lavish use of copper, even at £38 a ton, goes a long way to neutralise the much-boasted superiority of the single-trolley system in the matter of low first cost. If, as Mr. NELSON W. PERRY argues from the experience of Cincinnati, in an article which we reprint in the present issue, the remaining electrical and mechanical drawbacks of the double trolley have been successfully overcome, it would certainly seem as if they would come to it at last even in America, as being cheaper in operating expenses and giving rise to no telephone interference or electrolytic troubles; indeed, the makers of double-trolley equipment would do well to advertise their wares by the catch line, "Double your trollies and halve your troubles."

IF Mr. PERRY is correct in his statements—and human nature being much the same in the States as elsewhere, only more so, it is highly probable he is correct—neither the single nor the double trolley has as yet been adopted in America on its merits. The single-trolley system, it would seem, owed its vogue to the fact that manufacturers wanted to make 200 per cent. profit, and, the double-trolley system costing 30 per cent. more than the single, as then carried out, manufacturers had to choose between reducing their rate of profit in order that the double-trolley equipment might not be prohibitively expensive, and making out that salvation lay only with the single trolley. In Cincinnati, on the other hand, the tramway company and telephone company shareholders were mostly the same individuals; hence the remarkable local recognition of the many virtues of the then forlorn double trolley. Welded tracks also, about which we have heard so much lately, do not appeal to Mr. PERRY; both at Johnstown and Boston he states that this winter "the rails stretched and stretched until they could stretch no longer, and then they broke" at the rate of ten breaks to the mile. Pessimistic, however, as he is, he admits track welding may mitigate the electrolytic evil, though he will not admit that it can be eradicated in this manner; but, after all, eradication is only a question of degree, complete mitigation = eradication.

Cable Interruptions.—No interruptions are recorded this week.

Personal.—Mr. E. G. Jones, late assistant engineer to the St. James and Pall Mall Electric Light Company has been appointed electrical engineer to the Corporation of Cape Town.

British Association Attendance.—The number who attended the Oxford meeting was 2,321, a number in excess by several hundreds of last year's meeting, and the receipts were £2,175.

Honorary Degrees.—The honorary degree of D.C.L. was conferred by the University of Oxford upon a number of distinguished members of the British Association. Prof. Boltzman, M. Cornu, and Prof. S. P. Langley were among the recipients.

The Budapest Electric Underground Railway.—The Hungarian Minister of Commerce has granted the concession for the construction of the underground electric railway in Budapest. This line will be two miles in length. It is to be opened on April 1, 1896.

Street-watering by Electric Cars.—Toronto is said to be succeeding very well with its plan of watering the principal streets by the aid of the trolley. The streets on which the electric cars run are watered from a tank run by electricity along the car lines.

Obituary.—Mr. Charles Liddell, who has just died at the age of 81, took, as a partner in the firm of R. S. Newall and Co., at one time an active part in the laying of telegraph cables. He it was that, during the war in the Crimea, laid the cable between Varna and Balaclava.

Future Meetings of the British Association.—The next meeting of the Association will take place at Ipswich, and the 1896 meeting at Liverpool, and Toronto will, in all probability, be the scene of the 1897 gathering. Sir Douglas Galton will preside over the Ipswich meeting.

Electrical Trade Section.—At a meeting of this section on Tuesday last, Mr. Sydney Morse was elected Vice-Chairman, and after a few informal remarks with regard to electric traction on common roads and the rating of electric light stations, the section adjourned over the vacation.

Electro-Chemistry in Germany.—It is stated that the German Solvag Company of Bernburg has prepared plans for the establishment of works at Osternienburg for the electrolytical production of caustic potash, chlorine, and chlorite. Electricity has recently been adopted as the motive power at the bleach works of Messrs. Keferstein at Greiffenberg.

Belt and Rope Transmission.—As announced by Prof. Kennedy, in the course of the discussion on Mr. Crompton's Paper, the Société Industrielle du Nord de la France arranged at the beginning of the year for a series of experiments with a view of determining the power absorbed by belt and rope transmission under working conditions. These trials took place on the 7th, 8th, and 9th inst., a 200-H.P. engine being connected up to a 1,400-light dynamo.

Lightning.—During a heavy thunderstorm, which broke over the neighbourhood of Warminster on Friday afternoon last, about half-past four, two men who were turning hay in the middle of a large field, away from any shelter, were struck by lightning and instantaneously killed. Another man who was standing close by was knocked down, but escaped serious injury.—On Sunday the South Foreland lighthouse was struck by lightning, and a corner of the engine-house was knocked down.——On Wednesday evening last two roadmen who were sheltering in a harvest field at Holbeach while a heavy storm was raging were both killed by lightning.

The Electrician's Paradise.—It is satisfactory to learn, on the authority of a lively letter in yesterday's *Times*, that in Korea, at any rate, the electrician has the whip-hand over his employers. According to the writer of this letter, the only European not paid by the Customs who gets his pay regularly is the electrician at the Palace. The King and all his Court are so afraid of ghosts that they sit up all night. There are sorcerers—and the electric light also—to keep off the ghosts. If the electrician's pay falls into arrear the light apparatus breaks down, and cannot be repaired until he is paid up.

British Association Science Grants.—At the final meeting of the British Association Prof. Rücker read the synopsis of

Digitized by Google

grants of money appropriated to scientific purposes by the General Committee at the Oxford meeting. The following are a few of these grants: Prof. Carey Foster—electrical standards, £25; Dr. E. Atkinson—abstracts of physical papers, £100; Mr. Howard Fox—roduction of magnetic observations made at Falmouth Observatory, £50; Prof. A. W. Rücker—comparison of magnetic standards, £25; Prof. S. P. Thompson—uniformity of size of pages of transactions, &c., £5; Sir H. E. Roscoe—wave-length tables of the spectra of the elements, £10; Prof. J. E. Reynolds—electrolytic quantitative analysis, £40; Prof. A. B. W. Kennedy—calibration and comparison of measuring instruments, £50. A total sum of £1,093 was granted.

A New Filling Material for Thermometers.—Mercury, with which thermometers are ordinarily filled, has the drawback that it freezes when the temperature sinks to $-39°$ C. Alcohol, which is also used for the same purpose, frequently contains water, so that its registration can never be fully trusted. It has now been found, says the *Journal of Gas Lighting*, that toluol, one of the products of the distillation of coal tar, is applicable as a filling. It contains absolutely no water, and does not easily evaporate; it can stand a much lower temperature than quicksilver without freezing; and, when exposed to warmth, expands with great regularity. Further, it is very cheap; and, as it is much lighter than quicksilver, the tube of the thermometer can be made larger than is now usual; thus securing greater exactitude in the registrations. It is of a dark blue colour, which is easily distinguishable in the glass tube; so that the readings of the thermometer can be easily and quickly seen.

The Heilmann Electric Locomotive.—*L'Industrie Electrique* is responsible for the following:—The Compagnie des Chemins de Fer de l'Ouest, satisfied with the experiments carried out with the locomotive of M. J. J. Heilmann, has just ordered two new ones from the Société de Traction Electrique, which owns the Heilmann patents. The new locomotives will embody the improvements and modifications suggested by experience, with a view to the bringing out of a definite working type. The steam engine considered as best fulfilling the conditions imposed on the builders is the Willans. Messrs. Willans and Robinson have, therefore, received an order through their agent, M. A. H. Crozier, for two 1,500-H.P. engines, to be delivered in January and February next. The trials of the electric locomotives are to take place in May next, and it is understood that if the results are conclusive the Heilmann locomotive will be definitely adopted. We may add that M. Heilmann has recently been decorated with the Legion of Honour.

The Brooklyn Motormen.—The street boys of Brooklyn have found a new amusement, says the *New York Times*, and some of the motormen on the Third Avenue trolley line are on the verge of nervous prostration. The boys beg, borrow, or steal old clothes, until they have succeeded in getting together a very complete man's outfit. The next thing is a dummy, life size, which is well dressed, even to hat and shoes. A dozen or more conspirators, escorting this semblance of a man, stroll carelessly on to the track in front of an advancing car, talking busily. The bell is rung loudly, the boys scatter, and the dummy falls across the track. Then the jokers discover their histrionic talent. They rush back, apparently in terror, and make futile efforts to get the man out of danger. In the meantime the motorman, who is not the bloodthirsty wretch driving the car of Juggernaut that he is popularly supposed to be, is in an agony of horror. His hair fairly stands on end, and the veins stand out on his forehead as he uses all his muscle on the brake. If he succeeds in stopping before the car goes over the prostrate form, it is pulled off the track and sent flying into the car with wild shouts. The feelings of the unfortunate man at the brake are too vehement for utterance when he discovers the trick. The scheme is very successful just about dark, and, whichever way it goes, it is great fun for the boys.

The Electric Lighting of the Houses of Parliament.—In answer to a question in the House of Commons last week, Mr. H. Gladstone stated that the matter of providing the Houses of Parliament with electric installation had already received careful consideration. The evidence showed that no complete installation of electric lighting machinery and plant could be established within the building without occasional serious interference with its proper ventilation, and they had already some experience with a partial installation, which confirmed that view. The generation of electricity within the building had been abandoned both for that reason and because the boilers now existing were no longer strong enough to bear the strain of working both the ventilation and the lighting systems. The cost of constructing a complete electrical station outside the building in connection with the warming and ventilating arrangements had been considered, and it would probably reach £30,000 or £40,000; while the expenses of wages and main tenance would also be very heavy. The subject would receive further attention; but, having regard to all the circumstances of the case, it must be deferred for the present.

Search Lights.—The use of search lights at the recent naval manœuvres has, says the correspondent of a daily paper, served only one useful purpose—to show how little thought has been given to their proper use. More than one correspondent has described how, as soon as a torpedo-boat is supposed to be in the neighbourhood, the various ships begin darting their flashes about the horizon, so that the whole fleet is half-dazed by a series of irregular flashes. Among the bewildering alternation of bright light and black darkness the best eyes become helpless, steering and aiming are alike hindered, and the torpedo-boat runs a very fair chance of escaping in the confusion. A typical scene of this kind was witnessed in Belfast Lough when the Red (B) Fleet was thrown into something like a panic by the false alarm that a Blue torpedo-boat was at hand. Yet, says the correspondent, there is little room for doubt as to the proper use of the electric light by a fleet in such circumstances. The greatest enemy of torpedo-boats and the best protection against them for a squadron is daylight. The best use of the electric light is, therefore, to create artificial daylight. There is no difficulty in a naval force so using its electric force as to light up the whole fleet and the water around it. Into this illuminated sphere a torpedo-boat will venture at its peril. There are, of course, occasions when a squadron will prefer to remain in the dark. But a fleet that has been followed by the enemy into port has little motive for concealment, its numbers and whereabouts being known to the enemy, and this was the situation of the Red (B) Fleet. Cannot some of the electrical unemployed come to the rescue?

Atlantic Cables.—Electricians are well aware that the speed of working cables is dependent upon their length and the size of the conductor. The following figures relating to the Anglo-American Company's cables are interesting as showing the gradually increasing weight of cables:—

Date of laying.	Lbs. per mile copper.	Lbs. per mile g.p.	Length.	Working speed per minute.
1865	300	400	1,900	20
1873	400	400	1,885	30
1874	400	400	1,885	30
1894	650	400	1,847	45

The last of these cables was completed on July 27th last, and previous to its submersion the cable with the largest core was that of the Commercial Company, which contained 500lb. copper and 320lb. gutta percha, its length being about 2,200 miles. As operators were unable to transmit up to the full capacity of large cores, it became necessary to adopt automatic cable working, which was first introduced by the Anglo-American Telegraph Company in 1887, and enables so large a number as 45 words per minute to be sent through the latest cable. It is not generally known that on the very day that the last Anglo cable was laid, the 1874 cable, which had been some time interrupted, was repaired by Capt. Trott, of the s.s. "Minia," at a depth of nearly three miles. As showing the growing danger involved in the multiplication of cables in the North Atlantic, it was found that the break had occurred in close proximity to where the line was crossed by the Commercial Company's cable, and out of 274 miles of new cable expended in the repair, some 40 miles was necessitated in order to avoid interrupting the crossing line.

THE TELEGRAPH AND THE WAR IN THE EAST.

BY J. MORRIS.

The telegraph is playing a very important part in the operations of both combatants in the war now declared between China and Japan, but the Japanese are able to turn this invaluable weapon to better account than their rivals. They have taken possession of the lines and stations in Southern Corea, and are working them to advantage by their own men, trained, as our Royal Engineers are trained, in construction as well as in actual manipulation. The corps can be trusted to keep these lines in working order whilst Japan retains the control, and this will in itself be something of a novelty.

The Mikado's people have taken very kindly to the telegraph ever since its introduction in 1870. They had a couple of short lines, altogether about 40 miles in length, in operation at first, worked by Breguet alphabetical instruments, to which they managed to accommodate their rather extensive alphabet of 75 symbols. The stations, a dozen in number, were close together, and maintenance was not difficult. But in 1872 the Government launched out into a most elaborate system, the completion of the entire scheme occupying the Public Works Department about nine years. This was nothing less than a complete network of communications, bringing every outlying city of importance into direct touch with the capital. From 40 miles of line the circuits speedily grew into 4,000 miles, and at the present moment the wires measure close on 26,000 English miles, including several submarine cables of various lengths, one of the longest being that connecting Nipon (the main island) with Tsŭ-shima, the large island midway between Japan and Corea, a position which is just now of the utmost strategical importance. This bold undertaking has borne good fruit in more ways than one, and at the present moment there is hardly a point on the coast more than a few hours distant from a telegraph office, so that a fleet runner could convey the news of a hostile descent to the adjacent outpost, and a defensive force be called to the threatened region in less time than it would take the Chinamen to determine upon their point of attack. In 1876 this was demonstrated very clearly in connection with the Satsuma rebellion, the news of which was brought by a boatman to Kumamoto in one night, and flashed to the capital almost before the insurgents' rearguard had cleared from Kagoshima. The rebel General Saigo had always objected to the extension of the telegraph to his stronghold in Satsuma, and thus the lines had not been carried farther south, at that time, than Kumamoto, a town on the Satsuma border. But this was sufficient, as subsequent events proved, to give the central Government timely warning of Saigo's hostile intentions, and the loyal troops were quickly despatched to confront him before he could penetrate very far into undisturbed territory. Had not this means of communication been open to the Government, it would have taken a fortnight for a runner to reach the capital, and the rebels would the farther they went have been joined by sympathisers, rendering it far more difficult for the Mikado's forces to suppress them.

It is interesting to notice that the experience gained of the value of telegraphic communication by the Japanese in that civil war is being acted upon by them in Corea. They have promptly "requisitioned" the Corean lines, and have interdicted all messages other than those that concern themselves and their military movements. During the Satsuma affair in 1876 they closed the Japanese lines to all ordinary native traffic for some months, and allowed nothing but Government and international messages to pass over their wires from Nagasaki. In the matter of field telegraphy, too, the Japanese are adepts, their portable instruments, &c., being modelled upon apparatus which they imported from Europe. The posts are made in sections, with spiked bases to stick in the soil, and the wire runs out from reels on light hand-barrows. Altogether, it may be said that, if the Japanese are copyists, they have copied faithfully, and that they are able to appreciate to the full the value of the inventions which they thus assimilate. Practically, they absorb everything of any value that reaches their shores, and the unhappy patentee must console himself with the compliment implied in the fact of his having attracted so much attention from a progressive nation. When the first telephone receiver reached Japan from America it carried everything before it, and within a week or so there were some Edison receivers of native make being experimented upon. Such a handy instrument was sure to make headway in the East, and very complete police and fire-brigade systems of telephonic alarms and calls were instantly embarked upon. Both have rendered incalculable service in the Japanese metropolis and in all the principal cities of the Mikado's empire.

Many of the vessels of the Japanese are, of course, furnished with the electric light, and the manipulation of the projectors leaves nothing to be desired. In this respect they are as thoroughly up to date as might be expected, though they are not alone in the possession of this weapon, as some of the Chinese Pei-Yang squadron have search-lights also. It is to be presumed that the resolve of both combatants to exclude Shanghai from the sphere of their antagonism will conduce to the maintenance intact of our European-owned cables in the vicinity. Should the local mandarins conceive the idea, however, that the submerged threads off Gutzlaff are doing the Celestial cause a mischief, it will not weigh much with them that a promise of non-interference has been made. We may expect to find copper core doing duty as fishermen's toasting-forks, and the dielectric repairing holes in their sea-boots, as freely as it served those useful purposes on a former occasion. Should these undesirable incidents of a campaign evidence themselves in the near future, it is probable that the Japanese would afford every facility for the landing of a direct cable from Hong Kong on their own coasts. They have everything to gain, and nothing to lose, by keeping open their communications with Europe and America. A run like that the "Scotia" made years ago from the North Saddles to Hong Kong with the Eastern Extension cable might serve a beneficent purpose if repeated from Hong Kong to Nagasaki.

ELECTRIC STREET FIRE ALARMS.

We have recently had an opportunity of inspecting a new fire alarm system, fixed by the Single Wire Multiple Telephone Signal Company (Limited), for testing by the Metropolitan Fire Brigade, which offers several important improvements in the method of giving the earliest information of the outbreak of fires.

In order to make the matter clear, we may say there are at present about 700 street fire alarm posts now erected in London, working on a single wire between the call point and the station. Most of these are posts of the familiar form, painted red, with round tops and known as the "Saunders and Brown Patent"; but there are a few of other shapes as well as a small number of wall boxes. The existing street fire alarms are nearly all on what is known as the pull-knob system, because, after breaking the glass in the post or wall box, it is only necessary for a person giving an alarm to pull a knob or handle and wait at the post until the engine arrives to direct the firemen to the conflagration. By putting the line to earth a current is caused to pass out from the batteries in the fire station, having the effect of ringing a bell there and causing the dropping of the indicator bearing the name of the point from which the alarm was sent, and also ringing a repeater bell in the post, the stopping of which by the fireman at the station forms a reply that the call has been received. The firemen can also use the post to send certain conventional signals to the station indicating "More help wanted," "Serious," "Stop," &c. One of the drawbacks of the system is that accidental contacts on any of the wires cause false alarms, of which there are some hundreds a year in the metropolis, an unnecessary turn-out of the engines being the result. Means of distinguishing between calls and contacts are provided under this system, but the Brigades prefer to "turn-out" rather than run any risk. There are also a certain number of wilful false calls sent from call points; but it is to be hoped that the severity of the magistrates in dealing with recent cases of delinquents brought before them for this offence will have the desired effect of reducing the number of these senseless interferences with the

Digitized by Google

existing system for protecting the lives and property of the inhabitants.

The new and improved system, which is in operation from a point near the Borough to the head-quarters of the Metropolitan Fire Brigade, claims the following advantages:—

(1) Telephonic communication between the alarm post and the fire station.

(2) Immunity from accidental false alarms by contacts on the wires.

(3) Additional likelihood of detecting wilful false alarms.

(4) Telephonic communication between fire stations and firemen in charge of fire escapes at given points.

Obviously, in any fire-alarm system the first requisites are certainty and simplicity of action. There must be nothing that an excited caller can injure or put out of gear, and, therefore a telephone with flexible cord to place to the ear, even if it could be heard above the noise of heavy traffic, is inadmissible. The Single Wire Company effect the desired object by using a special telephone transmitter, the invention of their electrician, Mr. A. C. Brown, which reproduces the voice so loudly as to be heard at a distance of several feet from the post, notwithstanding the noises of the street traffic. The Chief Officer of the Fire Brigade (Capt. Simonds) in selecting the point referred to for the experiment, clearly had wisely determined to make the test a severe one. The call point, as well as a box in which the man in charge of the escape sleeps at night, is on a "shelter" in the middle of a road paved with cobble stones, and with the incessant traffic of the busy Borough thoroughfare passing immediately in front of it. Notwithstanding this, after the glass was broken, or the door opened with a fireman's or policeman's key, conversation, in the busiest part of the day, between the street alarm and the fire station was kept up with the greatest ease.

This telephone transmitter, or some modification of it, being remarkably loud and efficient, ought, therefore, to supply a demand in a wider field than that of fire alarms. The whole of the apparatus in the post can be covered with a grill so as to make it practically impossible that it should sustain any injury, either by the breaking of the glass or otherwise.

The method now adopted for securing immunity from accidental false alarms does away with the use of electric bells, which, as well as the indicators, are frequently set in motion by the earthing of the wires for testing, or by any stray current that may transit the line. In place of the bells in the fire station the Single Wire Company use a telephone receiver, which becomes an electric hooter when a rapid make-and-break is set up by smashing the glass or opening the door of the post. As it is practically impossible that currents of such frequency can get upon the line accidentally, it seems clear that accidental calls will be entirely eliminated, thus saving a great deal of annoyance, loss of time, and fatigue to the brigades.

When anyone sends a wilful false call, obviously the best plan for the culprit is to avoid observation, and to retire as rapidly as possible from the scene of action. To send an effective alarm under the new system it will be necessary for the caller to stop at the post to reply to the questions of the fire station; in addition to which, when the glass is broken, an electric "hooter" sounds at the call point, as well as in the station, directing the attention of the police and passers-by to the spot.

When we inspected the system we were informed that about seven or eight days before, Capt. Simonds had called the attention of the secretary of the Single Wire Company to the desirability of the fire station being able to communicate, on the single fire alarm wire, with the firemen in charge of fire escapes in the streets, so as to enable the station attendant to give instructions for the escape to be sent immediately to a fire when the escape is nearer to the place of operations than the station. Seeing that the line to the post is necessarily insulated or disconnected until the glass is broken or the door opened, it is obviously impossible to ring an electric bell in the fireman's shelter, which is always close to a call-point; and it seemed at first that it was not possible to attain the desired result without using an independent wire.

A method of effecting the communication, without in any way interfering with the fire alarm, had, when we saw the system, however, been worked out by the electrician of the Company and was then in operation. This was effected by discarding bells and using a telephone trumpet, which is actuated by rapid electric impulses in such a way that the current necessary for working the fire alarm is unable to escape to earth. The electric hooter in action is sufficiently loud to awaken a sleeping fireman, or to attract his attention if at some distance from the box. Under this arrangement the fireman in charge of an escape is always in telephonic communication with the station.

It will be seen from the foregoing description that, if this system be adopted and found to work as well in practice as it certainly did experimentally, engines in future can proceed direct to the fire instead of having to go first to the call-point, which may be out of their way; and that, where necessary, fire escapes and ambulances can be ordered to the burning building when the alarm is first given. In addition to this, firemen can go at any time to given points and converse with the fire stations; and, as the fire stations have electric communication with the police, the latter can also utilise the system, if need arise, to communicate with their head-quarters. The Single Wire Company's system of street fire alarms certainly appears to be a great advance on existing devices, and seems to provide all facilities and safeguards that can be desired.

A great authority on matters connected with the extinguishing of fires recently expressed the opinion that, to insure safety of life and property in London as far as possible, by enabling the engines to be on the spot within the shortest time after the discovery of fire, 10,000 additional street fire alarms would not prove sufficient, adding that he did not suppose the County Council would provide money for so large a number. Some time previously the manager of a fire insurance company, by way of justifying an increase of premium from 7s. 6d. to 12s. 6d. per cent., said that, from his Company's experience of recent fires, they had to make good not only the loss caused by fire in the building insured, but damage occasioned by a conflagration which might have originated in any of ten adjoining buildings on either side. It is well known that most of the principal London office have been heavy losers by recent fires, and premiums for manufacturing and warehouse premises have been lately considerably increased. We venture to make a suggestion for the consideration of the fire offices. A fire, as a rule, is easily extinguished if appliances are promptly on the spot—the fire at St. Mary Axe might probably at the commencement have been extinguished by a single bucket of water, and that at Finsbury have been confined to one building had the engines been enabled to reach the spot within a quarter of an hour of the outbreak—would it, therefore, not pay the insurance corporations to bear some part of the cost of additional fire alarm call points, especially in the Metropolis? The Companies used to contribute to the cost of the fire brigades, and if the "perpetual want of pence which vexes public men" prevents the authorities providing sufficient protection, such an offer from the Companies might not only induce the County Council to add to the number of existing fire alarm posts, but, by calling public attention to the matter, put pressure upon them to equip the Metropolitan Fire Brigade in a manner not only worthy of London, but such as to give the most adequate protection possible to the lives and property of its citizens. To maintain 10,000 street fire alarms, in addition to the 700 already existing, in the "province covered with houses," which now embraces nearly 150 square miles, would cost some £60,000 a year; and it is probable that if the forty chief fire insurance companies were each to subscribe an average of £500 per annum (which they would surely save in reduced claims), aggregating £20,000, the much-needed work would be carried out, at once effecting a great saving of life and property.

Unless steps be taken to provide the promptest possible notification of the outbreak of fire, with the lofty buildings, the façades of which are full of windows, everywhere being erected throughout the country, there will, sooner or later, in some combination of circumstances, or owing to a high wind, be such an outbreak or simultaneous conflagrations as will overpower the efforts of the brigades, and call attention in an unpleasantly emphatic manner to the fact that we are perpetually in peril from that "good servant" which is "a bad master."

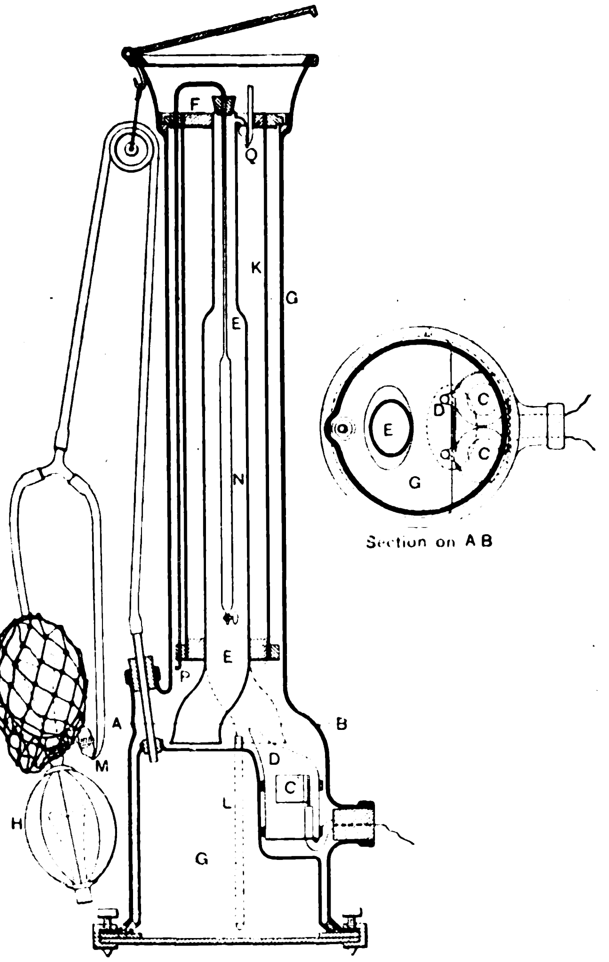
THE NABER VOLTAMETER.

Prof. Kohlrausch has recently expressed his surprise that the most ancient instrument for measuring electric currents—viz., the gas voltameter—is so seldom used. He attributes this to the difficulty in arranging for the separate collection of hydrogen without gradually increasing the resistance of the instrument, and, in order to reduce this resistance, he has brought the electrodes close together, thus sacrificing the advantages of collecting the gases separately. Herr Naber, of Amsterdam, has recently devoted much attention to the construction of an improved voltameter, which, he claims, is capable of measurements of great accuracy, and which, therefore, may be used as a standard laboratory instrument. The arrangement will be seen in the accompanying illustration, which shows a sectional elevation of the instrument and a horizontal section upon the plane A B. The electrodes C are spiral in form, and are placed under the glass hoods D, which



The Naber Gas Voltameter. Sectional Elevation.

terminate in nozzles about 4mm. diameter. These hoods are held together by rubber bands, as shown. A burette, E E, fully graduated along its stem, is supported from a collar, F, and is capable of rotation, allowing either one or both of the gases to be collected, or of being turned in the position shown in the illustration, thus shutting off the gases altogether from the burette without interrupting the current passing between the electrodes. The burette is contained in an outer glass vessel G, which is half full of the electrolyte—weak sulphuric acid. In order to neutralise the pressure of the gas to be measured, arrangements are provided for adjusting the level electrolyte outside the burette with the level of the liquid within this part of the instrument. This is effected by air pump H, by which air may be forced into the air vessel G. This vessel is filled with the electrolyte, and a tube passing nearly to the bottom allows the liquid to be forced out into the annular space between the outer vessel G and the cylinder K, in which the burette is fastened. The weight of the hanging air-pump H H keeps a kink in the rubber tube M, which is otherwise open. On raising the air-pump this kink disappears, and the electrolyte enters the receiver G through the tube L, the air escaping at M.

An air thermometer, N, is suspended in the burette, and by its indications corrections may be made for temperature and for barometric pressure. The open end of the thermometer is turned up at P to prevent the ingress of any bubbles of gas. A tube, Q, closed by a kink, as shown, or by a stop-cock, allows the gas to escape from the burette. The rest of the construction of the apparatus is clearly shown in our illustration. Electrolytic investigations in chemical laboratories are now becoming so common that an instrument of this kind should prove very useful. The direction and approximate magnitude of the current can be seen by simple inspection of the electrodes. The current in amperes can be determined by turning the burette on and off at definite and suitable interval of time; but its chief use, no doubt, is to measure the total quantity passed in coulombs, or fractions of a Board of Trade unit.

THE DOUGLAS-LAXEY ELECTRIC TRAMWAY.

This interesting little line, which was opened to the public on the 28th ult., was constructed under the Douglas and Laxey Electric Tramway Act, passed by the legislature of the Isle of Man on May 30, 1893, and promulgated by the Governor, Council and Keys, in Tynwald assembled, on Nov. 17, 1893. It is a double line throughout, 3ft. gauge, and 7 miles long. As will be seen from the profile of the line, it starts at a point 20ft. above mean high water, and rises in a distance of about 1½ miles to Lagbirrah, where it is 258ft. above the sea. It then falls to the Groudle Glen, which it crosses by a fine stone bridge of three arches. Rising again it reaches the highest point when it crosses the public road to Laxey at the Half-Way House, at a height of 337ft. above the sea. After once more descending, and reascending, it finally descends to Laxey, where the terminus is just below the town, at a height of 115ft. above the sea. The steepest gradient is 1 in 20, and the sharpest curve 100ft. radius.

There are two power stations, one at Douglas, and one near Laxey. The former is equipped with three Lancashire boilers, working at 120lb. pressure. Three compound side-by-side high-speed vertical engines drive, by link belts with jockey pulleys, two "Manchester" dynamos, each having an output of 500 volts, and 100 amperes, and one "Mather and Platt" dynamo of the same output. The switchboard is fitted in accordance with the requirements of the Board of Trade, with a subsidiary board for measuring the currents returning through the earth connections. The Laxey power station is similar to the Douglas station, but equipped with only two boilers and engines of the same size, and two "Mather and Platt" dynamos of similar output.

The most remarkable feature of the line is the use of accumulators. At Groudle Glen, 2½ miles from Douglas, there is a battery of 240 cells, manufactured by the Chloride Electrical Storage Syndicate. These cells have a capacity of 140 amperes for 3 hours, or 70 amperes for 9 hours; and have a level E.M.F. curve, which they maintain up to the end of discharge; they also have a very high rate of discharge. Half the cells of the battery are of the protected type, with teak separators and asbestos diaphragms, similar to those now being used on the Birmingham Tramways, and the other half unprotected. The cells are charged direct from the line or from a motor-generator of special design, which gives the required additional pressure. They serve not only the function of supplying the extra power required at times of maximum demand, but it is intended during the winter months to work the light cars, which will then be sufficient for the traffic, after the close of the tourist season, entirely from the battery, charging it only once or twice a week as occasion may require.

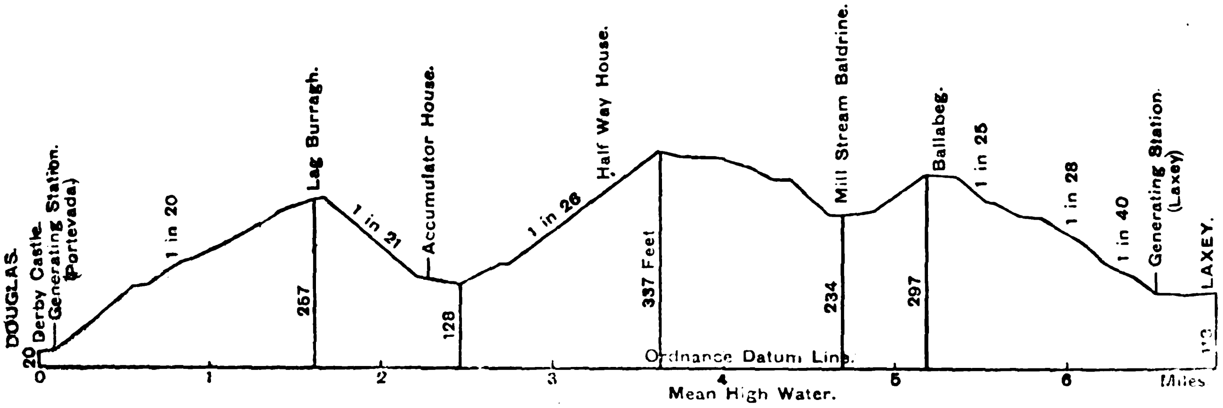
The conductors are on the overhead system, devised some years ago by Dr. John Hopkinson. Instead of the current being collected by a trolley wheel, as is usually the case, it is collected by two bars, each of the width of the car, and placed at each end. (See *The Electrician*, Vol. XXXII., January 19, 1894, p. 291.) They rub along the under surface of the wire

Digitized by Google

and make an excellent contact. The bars clear the insulators in passing under them by about 2in., the forward bar making contact before the trailing bar breaks contact. The collecting bars are constructed with an hinged joint controlled by a spring, devised by Dr. Edward Hopkinson, which regulates the pressure of the bar against the wire. The conductors are of hard drawn copper wire carried from insulators fixed to the cross arms of steel poles, erected with concrete bases midway between the two lines of rails. In addition to the working conductors there is a heavily-armoured Callender feeder cable of 37/14, extending about half the length of the line, and laid underground. The conductors are broken at various points and fitted with fuse boxes and connecting links, so that they can be connected and disconnected, as required by the regulations of the Board of Trade. The return is through the rails, which are bonded with copper strips riveted to the under flange of the rail.

The rolling stock consists of nine 38-passenger motor cars, and 12 open trailers. There are two 30 H.P. motors on each motor car, single reduction geared, working one on to each axle of each bogie. These motors are capable of together giving 3,000lb. tractive force at the periphery of the wheels. The motor cars with their electrical epuipment weigh 9½ tons. The trailer cars weigh 4 tons, and will seat 44 passengers; hence a fully loaded train of one motor car and one trailer car weighs 19 tons. The cars are fitted with powerful hand brakes, and also with Milnes' continuous automatic emergency brakes, which can be worked by hand or come automatically into action if a train parts its couplings. They are also fitted with Milnes' combined coupling and buffer. The nine cars can maintain a 15-minute service in each direction, and can thus provide for a traffic of some 320 passengers per hour. Since the opening of the line 30,000 passengers have been carried in one week.

The speed at which this line has been constructed and equipped with electrical plant is remarkable, although involving heavy rock cuttings, several embankments, and a massive stone bridge, it has only taken seven months to construct. The engineer is Mr. F. Saunderson, and Mr. Alex. Bruce, J.P., of Douglas, is the chief promoter and Chairman of the Company. The contract with Messrs. Mather and Platt was not let till the beginning of March, from this it will be seen that the electrical plant was designed, constructed, and erected in under five months. The whole of the electrical plant was designed by Dr. Edward Hopkinson.



PROF. KENNEDY'S PRESIDENTIAL ADDRESS TO SECTION G.

THE CRITICAL SIDE OF MECHANICAL TRAINING.

While there is no place in the kingdom more suitable for a meeting of the British Association than Oxford, and certainly no place in which it is more delightful for the members to meet, it is yet to be admitted that there are few places which have much less in common with the special work of Section G. Nominally devoted to "mechanical science," the section has for many years specially dealt with those branches of applied mechanical science which constitute the business of the engineer—to quote the well-known words of the Royal charter: "the art of directing the great sources of power in nature for the use and convenience of man." The association of this ancient and learned city with boilers and chimneys, with the noise and racket of ordinary mechanical work, seems an incongruity. Even the harmless necessary railway station is kept as far away as possible, and the very river flows with a quiet dignity which seems to shut out the thought of anything more mechanical than the most ancient and futile of water-wheels.

Naturally enough these considerations did not tend to make more easy the choice of a subject for this address, and I have come very near to agreement with a recent critic in the opinion that presidential addresses are, in fact, almost immoral in the nature of things and fit only to be abolished. Finally I decided upon taking up my present subject, as being one in which the academic rather that the technical side of our work comes to the front, while at the same time it does not lead me out of lines in which I have been able, in past years, to work myself. It is now 20 years since I first took any active part in the scientific training of engineers, and five since I ceased to do so. I have often wished that I may have been at all as successful in teaching others at University College as I was, at the same time, in teaching myself. And since I have ceased to teach I seem to have been spending my time in finding out how much better I could now do it than was possible when I was actually engaged in it. This may be pure imagination on my part; there is nothing more easy, as we all know, than to suppose that we know best how to do the things that other people do, and not the things we have to do ourselves. Indeed, I understand that this is the recognised attitude of the really superior critic. If, however, in anything which I have to say, it should seem that I am finding fault with what is now being done, I may at least point out that most of all I am finding fault with myself for not having done right when I had the opportunity—an opportunity which can now never recur. Indeed, instead of the decorous and unobtrusive heading which I have given to this address, I might have indicated its general lines almost as truly if I had entitled it "The Regrets of an Emeritus Professor"—a name which, on a suitable binding, might even have secured it a sale at the railway bookstalls.

I know well—too well—that in the present congested state of the engineering profession there are many of us who do not like to hear the word "training" mentioned at all. It seems to mean merely the preparation of more lads to struggle for a share of work that is even now insufficient to go round. There is no doubt much to be said for this point of view. But against it one must remember that all other professions are equally full, and that, after all, lads must do something. The fault is surely that there are too many lads! If our population is really to go on increasing as rapidly as at present—the benefits of which Sections D, E, and F might have a joint meeting to discuss, if not to discover—it is inevitable that demands should come for more and more complete professional preparation. The man of exceptional parts will come to the front under any conditions, training or no training, in the future as in the past. But for ordinary men—that is, for 99 per cent. of us—it is essential that no advantage should be given to a rival in the fierce competition of life, and for them, therefore, it is of an importance hardly to be exaggerated to obtain the most complete and perfect training possible. At the same time, and on purely general grounds, it can hardly be denied that to raise the standard of our

Digitized by Google

profession is indirectly to confer a benefit on the whole community. I hope, therefore, that in making certain suggestions about the training of engineers, it will not be thought that I am desirous of increasing their number, which is really an end as far as possible from my own wishes. Whether the number increases or stands still or falls off, it is of importance from every point of view that those who come forward should be as well prepared as possible. And even the most conservative of us are compelled to recognise that the standard required in engineers' offices now is enormously higher than it was 30 years ago. This may truly be either the cause or the effects of improved training, but in either case it has made the training itself a necessity.

The particular aspect of mechanical training of which I wish to speak is its critical side. I do not know how a man should be trained to be an inventor. I would not tell anyone if I did! To be a creator in mechanical matters—which, however, is a quite different thing—is a faculty given only to a very few, and with them it is "born, not made." Many of us, however, without being either inventors or creators, have sufficient natural aptitude or inclination towards things mechanical to form a basis for the trainer or educator to work on, with some hope that he may be of service. About the sciences which should be taught to such men, or the methods of teaching them, about the extent and nature of their experience in shops or on works, I do not intend to speak. I shall confine myself to one aspect of the training only, an aspect which is perhaps not always sufficiently clearly kept in view—the aspect which I have just called the critical side of mechanical training. An engineer is a man who is continually being called upon to make up his mind. It may be only as to the size of a bolt; it may be as to the type of a Forth Bridge; it may be as to the method of lighting a city; or only as to the details of a fire-grate. But, whatever it is, once it is settled it is decided irrevocably—it is translated into steel and iron and copper, and cannot be revoked by an Act passed in another session. The time given him in which to decide may be a day, or a month, or a year, but in any and every case (so far as my own experience goes) it is about one-tenth part of the time which he would like to have. It is only in rare cases that the decision is obvious—most often there are more courses open than even the most facile politician ever dreamt of. The matters are too complex to be dealt with mathematically or even physically; even if they were not, there are few engineers who would have the special capacity to handle them. Moreover, their solutions are seldom "unique." From this point of view, the whole use of college training, of workshop practice, of practical experience, is to provide the engineer later on with the means of critically examining each question as it comes up, of reviewing systematically the *pros* and *cons.* of each method of dealing with it, of coming finally, rapidly, and positively to some defensible decision, which may then be irrevocably carried out.

In the case of a problem in pure mathematics or physics, where only one right solution can exist, that solution is arrived at by the help of a thorough knowledge of the science in question; there is little room for the critical faculty except as to method; the result is either right or wrong. With our work, on the other hand, solutions of all problems except the very simplest—in other words, decisions on all points which present themselves—can be arrived at only by a process of criticism applied to the problems, to their statement, to their condition, to all their many possible solutions. The development of the necessary critical faculty should be one of the chief aims of every teacher and every student. A scientific training cannot make a man an engineer. Perhaps it is impossible for anything to make a man an engineer unless he has grown that way from the beginning. But a scientific training may make him, or at least give him the possibility of making himself, a critic.

In the vigorous attempts which have been made to specialise the education of engineers very early, I am afraid that the idea of teaching subjects is sometimes too prominent, to the neglect of matters less obviously useful. It is, of course, one thing to know a subject from the examination point of view, and quite another to be able to think about it, and still another to be able to write about it. In particular, I have often regretted to find how little attention has been given to a matter which, perhaps, may be called literary rather than scientific, but which is all-important in criticism—I mean to the power of expression. It is not easy to overrate the importance to the engineer, as to other folk, of the power of saying clearly what he means, and of saying just what he means. I do not mean only of doing this for its own sake, but because if a man cannot say or write clearly what he means, it is improbable that he can think clearly. By the power of expression I do not mean, of course, the mere power of speaking fluently in public, a thing which appears physically impossible to some people. I mean rather the power of expression in writing, which carries with it clearness and consecutiveness of thought. It is difficult to know how this matter can be taught, but at least it can be insisted upon probably to a much greater extent than is commonly the case. A man requires to see clearly not only the exact thing which he wants to say, but the whole environment of that thing as it appears to him. Not only this, but he must see the whole environment of the same thing as it appears to the persons for whom he is writing, or to whom he is speaking. He has to see what they know about the matter, what they think, and what they think they know, and if he wishes to be really understood has got to do much more than merely write the thing he means. He has carefully to unwrite, if I may use the expression, the various things that other people will be certain to think that he means. For, after all, the great majority of people are very careless listeners and readers, and it is not for the small minority who are really exact in these matters that one has to write. Moreover, it is a great help to clearness of thought and expression to keep before one always an ideal audience of people who will certainly misunderstand every single sentence about which any misunderstanding is in any way possible, and some others as well.

In attempting to think out or to discuss any question, whether it be technical or non-technical, in fact, as long only as it is non-political, the first necessity is probably a knowledge of the question itself, and not only this, but also a proper understanding of its whole environment. This knowledge must be of such a kind as to distinguish what parts of it are important, what parts of it are unimportant, what parts can be described in two sentences, and what others may require as many paragraphs; what parts affect the result but little, however large they seem; and which ones must be considered vital, although their very existence is difficult to discover. The faculty which enables a man to handle his knowledge in this fashion may be summed up in the single expression "sense of proportion." Moreover, the knowledge, to be of real value, must be as totally free from prejudices and prepossessions as in the most rigorous branch of pure science, and as thoroughly imbued with a healthy spirit of scepticism. One is accustomed to think of engineering work as mainly constructive; but, after all, it is quite as much critical. In almost every department of mechanical work there are half-a-dozen ways of solving any particular problem. In some fashion or other the engineer must be able to judge between these various methods—methods which are often very much alike, but each of which may possess certain particular advantages and certain particular drawbacks. The arithmetical criticism which merely counts the advantages and drawbacks, and puts an equal number of the one against an equal number of the other, is common enough, but obviously useless. The very first necessity to the critic is that he should have what I have just called the sense of proportion—a sense which will enable him to distinguish mere academical objections from serious practical difficulties—which shall enable him to balance twenty advantages which can be enumerated on paper by one serious drawback which will exist in fact—which will enable him, in fact, to place molehills of experience against mountains of talk. It is perhaps a doubtful point how far this sense of proportion can be taught at all. No doubt it can only be built up upon some natural basis. I am sure that in engineering we all know men whose judgment as to whether it was advisable to take a particular course we would accept implicitly, because we know that it is based on large general criticism, in spite of the most elaborate and specious arguments against it set down on paper. Any third-year student—not to go still further back—can criticise perfectly along certain very narrow lines, just as anyone can learn the rules of harmony, and can write something in accordance with them which purports to be music. But, after all, the music may be music only in name, and the criticism may not be worth the paper it is written upon, however formal it may appear to be, unless the writer is thoroughly imbued with a sense of the proportionate value of the different points which he makes. To take the commonest possible case, I daresay we have all of us heard certain methods, mechanical, chemical, or other, stigmatised as totally wrong and absolutely useless because they contain certain easily provable errors. I am sure, too, that most of us could give illustrations of cases in which this has been said with the very greatest dogmatism when the errors of the impugned method are not one-tenth part as great as the equally unavoidable errors of observation in the most perfect method.

Probably the best special education in proportion which a man can have is a course of quantitative experimental work. I say quantitative with emphasis, as meaning something much more than mere qualitative work. Here, I think, comes in the usefulness of the engineering laboratory. We require that the training should be not only in absolute measurement, but in relative measurement, the latter being quite as important as the former. Many kinds of measurements stand more or less upon a level as a training of the faculties of observation in themselves, but no single kind of measurement is sufficient as a training in proportion. A year spent in calibrating thermometers or galvanometers might make an exceedingly accurate observer in a particular line, but it would not give the observer a knowledge of what even constituted accuracy in other directions; for accuracy is a relative and not an absolute term. In most engineering matters the conditions are, unfortunately, of a most complex kind —so complex that our problems are incapable of any solution

Digitized by Google

sufficiently exact to satisfy the mathematician or physicist. The temptation to treat these problems as the mathematician treats those with which he deals—namely, to alter the assumed conditions in order to get an exact solution—is a very strong one. I am afraid it is most strong often in those engineers who are the best mathematicians. It is a temptation, however, steadily to be resisted. We must assume our conditions to be what they actually are, and not what we should like them to be; and if we cannot obtain an exact solution of our problem with its actual conditions, so much the worse for us, not so much the worse for the conditions. Our first duty is generally to find out the conditions; if they are disadvantageous (in fact I mean, and not merely in the problem), to alter them if they can be altered, but not to ignore them because they are inconvenient. We have, then, to find out the extent to which the known conditions permit any exactness of solution at all; and, finally, we have to keep this in view as a measurement of the highest accuracy which is attainable. To work out certain branches of the problem with such minuteness as to give us apparently very much greater accuracy than this is not only useless, but is apt to be positively misleading, as giving an impression of an accuracy which has no real existence. The relative value of accuracy in different sets of observations is in itself a matter in which a sense of proportion is wanted, and often very badly wanted. Where one has to measure half-a-dozen things, of which two are very easily measured and the remaining four are only measurable with great difficulty, it is only human nature that we should spend our energies on getting extremely accurate results with the first two, and roughly do our best with the others. It is very difficult under such circumstances to remember that the accuracy of the whole is not the accuracy of the best part of our work, but of the worst.

The extraordinary effect of a want of sense of proportion is nowhere better shown than in the absurd statements which are constantly made as to technical matters in public prospectuses, and the still more absurd statements made in those very numerous documents of a similar kind, of which some of us see a great many, but which do not finally emerge into public view. Fortunes are apparently to be made by inventions which, although doubtless ingenious, yet only concern one way of doing a thing which could be done equally well in half-a-dozen other ways. Everyone is expected to run after a piece of apparatus which is to save 50 per cent. of something, the total cost of that something, however, being so very small that nobody cares to save in it at all. I need hardly mention the all too-common case where a contemplated saving of 10 per cent. in the cost of a material works out yearly to an amount much more than equal to the whole cost of the original article. I believe that experimental work in an engineering laboratory can educate this critical sense of proportion very admirably in a number of ways. In the first place, it directs quantitative work into very varied channels, and not along one particular line. Secondly, it compels the observer to combine a number of measurements in such a way that the relative importance of accuracy in each can be seen. In the case of an engine trial, for instance, the combined results are affected by the accuracy of measurements of the dimensions of the machine, by the apparatus and methods used for measuring the water, by the indicator and by its springs, by the speed counter, by the thermometers, and so on. An error of 1 per cent. in counting the revolutions is just as important as an error of 1 per cent. in measuring the water, or in measuring the mean pressure. I am afraid that one could point to a good many cases in which this has been more or less forgotten. Then by making a series of measurements all in absolute quantities, the relative importance of each quantity to the desired total result can be seen. Thus it will be found that changes in certain quantities affect the total result to a very small extent, while changes in others affect it very largely, so that not only is the accuracy with which different quantities can be determined very different, but also the same degree of accuracy is of very different importance according to the particular quantity to which it refers. Once it is found that a final result is exceedingly little affected by a particular set of changes, it ceases to be of importance to measure or observe those changes in any extremely minute way, and of course the reverse holds equally good. Finally, and this, perhaps, is the most important matter of all, measurements in such a laboratory are made to a great extent under the complicated conditions under which the actual final result has to be obtained in practical work. They are not made under the conditions that will insure the greatest individual accuracy of each result.

It will be seen that throughout, but particularly in the last two points which I have mentioned, the work of an engineering laboratory is in intention and in essence different from that of a physical laboratory. The aim of the latter is to make its problems as simple as possible, to eliminate all disturbing elements or influences, and to obtain finally a result which possesses the highest degree of absolute accuracy. In most physical investigations the result aimed at is one in which practically absolute accuracy is attainable, although attainable only if infinite pains be taken to get it. It is the business of the physicist to control and modify his conditions, and to use only those which permit of the desired degree of accuracy being reached. In such investigations it sometimes becomes almost immoral to think of one condition as less important than another. Every disturbing condition must be either eliminated or completely allowed for. That method of making the experiment is the best which ensures the greatest possible accuracy in every part of the result. The business of the engineer, on the other hand, is to deal with physical problems under conditions which he can only very partially control, and the conditions are a part of his problem. He does not, for instance, experiment with a steam-engine so made that it can work with a Carnot cycle. It is in the nature of the case that he must experiment with a much less perfect machine. In burning fuel he does not use apparatus specially made to absorb the whole heat of combustion, but in the nature of the case has to investigate the behaviour of apparatus in which a very large part of that heat is unavoidably wasted. So one might go on through an immense number of instances. Perhaps the whole matter may be best summed up by saying that in a physical laboratory the conditions of each experiment are under the control of the experimenter, and are subservient to the experiment itself. In an engineering laboratory the conditions form part of the experiment. However much more difficult or complicated they render it, they still unavoidably form part of it—an experiment under any other conditions, or with those conditions removed, would *ipso facto* be irrelevant.

Whenever the whole matter seems to be completely mastered from one point of view, it is only to find, with a little more experience, that from another point of view everything looks different, and the whole critique has to be started afresh. Machines cannot be finally criticised—that is to say, they cannot be pronounced good or bad—simply from results measurable in a laboratory. One wishes to use steam plant, for instance, by which as little coal shall be burnt as possible. But clearly it would be worth while to waste a certain amount of coal if a less economical machine would allow a larger saving in the cost of repairs. Or it might be worth while to use a machine in which a certain amount of extra power was obviously employed, if only by means of such a machine the cost of attendance could be measurably reduced. In fact, what may be summed up in the phrase the "worth-whileness" of economies, is in itself a matter on which a whole Paper might be written. Unfortunately, the latter points which I have mentioned are just such as cannot easily be measured in laboratory work, or, indeed, in any other way whatever, except by actually using the apparatus in question. All that can be said is that a careful training in the critical measurement of comparatively simple points fits a man more than anything else to gauge accurately the importance of such other matters as I have mentioned.

Is there, then, any general standpoint from which mechanical criticism can be directed? Certain points are obvious, but probably the whole matter cannot easily be generalised. A city has to be supplied with water; there are three requisites—that the water should be of proper quality, of sufficient quantity, and that it should be brought in at a reasonable cost. But in such a case the first two are so enormously more important than the third, that the ideal is comparatively simple (of course, this is quite a different thing from being simply reached). A city has to be supplied with electric light: the essential conditions are similar. But in this case there are so many qualities which are equally proper, and there are so many different ways of bringing it in in sufficient quantity, that the third point—namely, the cost—becomes especially important. A factory has to be driven by steam power; the amount of power that is wanted can be produced by so many different types of engine and boiler—all capable of approximately equal economy, and all claiming equal freedom from breakdowns—that the choice is a peculiarly difficult one from the critical point of view. It seems almost impossible that a criticism on any one basis could meet all the three cases which I have supposed, unless that basis were that the thing supplied should be the absolutely fittest, having regard to all the conditions of each case and the relative importance of each condition. Possibly in all cases we could get at some generalisation which would show us which was the absolutely fittest, if only the necessary data were in any way complete, which they very seldom are. Perhaps in one sentence we may say that that scheme, or system, or machine, will be the absolutely best in any particular case which will the longest survive and maintain its place in its particular environment. I cannot doubt that this development of Darwinian ideas in the world of the inorganic is a legitimate one. Of course, the problem would be comparatively easy in each particular case if only the environment would stand still. It would even be comparatively easy if we knew how the environment was going to alter, but this we are unable to do. We only know that it certainly will change and will go on changing, and that therefore the things which we make now have not got to survive in the conditions in which we make them, but have got to survive through some new sets of conditions of which we know nothing. I do not think the difficulty is in any way met by the popu-

Digitized by Google

lar method of guessing at what will be wanted 50 years hence, which generally means simply guessing at something very big. It is of no use making our ships or our engines of a type which we choose to imagine will be that of 50 years hence. If we do they will be of no use to-day, and for that very reason they will not even be in existence, useful or other, at the end of the 50 years. Sufficiently sad illustrations of this will occur to everyone in very different directions. I hope I shall not be considered churlish in saying that I do not think that the men who have worked on this principle have really been far-seeing, or have really brought us much forward. They have been men often of genius, often of great personal fascination, always of immense imagination ; but they have proceeded by methods essentially opposed to anything like the gradual evolution which must occur in technical as it does in natural matters, and in too many cases the results of their labours have not even been giants, but only monsters.

As to what causes one thing to survive rather than another we can only speak very generally. Mere survival may come about by the accident of a peculiarly tough constitution. A few engines built in the times of James Watt are still to be found at work in our own day, but can no more be taken as the fittest type than some solitary megatherium would be who, having outlived all his contemporaries, was able in after ages to look down upon his pigmy and short-lived successors. Mere length of life in such a case may be a mere accident, and is not itself a proof of fitness. We have it thrown at us every now and then that our engines nowadays do not last like the old ones, as if the mere existence of a very old machine were a proof of its virtues. It is certainly a proof of the excellence of its construction—or, as one may say, of its constitution—and perhaps also of the very small amount of work it has done in proportion to its life and its dimensions. It is sometimes, I am afraid, rather humiliating to have to remember that, to a very great extent, the question of the fittest, so far as it affects us, is a financial one. In manufacturing processes efficiency and economy tend to survival because they lead to decreased cost of production. In structures or other large permanent works those types tend to perpetuate themselves which require the least material—that is, in which the material used is disposed to the best advantage—and in which the outlay on labour is also smallest, assuming, of course, equal fitness in other respects.

I think we may fairly assume, therefore, that efficiency and economy are both legitimate criteria as to ultimate fitness, and will remain so. Moreover, they are both matters in which measurements can be made, and as to which judgment can be guided by such measurements. But there are other characteristics, not directly measurable, by which we can in some degree form an opinion as to the ultimate fitness of things or processes.

One set of considerations which has great critical importance is summed up in the word simplicity. This does not mean fewness of parts. Reuleaux showed long ago that with machines there was in every case a practical minimum number of parts, any reduction below which was accompanied by serious practical drawbacks. Nor is real simplicity incompatible with considerable apparent complexity. The purpose of machines is becoming continually more complex, and simplicity must not be looked at as absolute, but only in its relation to a particular purpose. There are many very complex-looking pieces of apparatus in existence which work actually so directly along each of their many branch lines as to be in reality simple. I believe it almost always happens that the first attempt to carry out by a machine a new purpose is a very complicated one. It is only by the closest possible examination of the problem, the getting at its very essence, that the machine can be simplified, and this is a late and not an early stage of design. If a mechanical problem is really only soluble by exceedingly complicated apparatus, it generally becomes a question whether the solution is worth having. There is no impossibility in making a machine that will do anything. But the very simplest possible form of apparatus which would wash our hands for us in a suitable manner is probably so very complicated that for many years to come at least that operation will be performed by manual labour. Very closely allied to simplicity is what I may call directness. In nearly all mechanical processes certain transformations are unavoidable. In many mechanical processes, as I have recently had occasion to mention, a very large number of transformations is at present practically unavoidable. I myself cannot help thinking that probably one of the most distinct signs of fitness is a reduced number of transformations, the bringing of the final and the initial stages as close together as possible, and cutting out altogether the apparently worthless middle processes. But any generalisation of this kind must be very cautiously handled ; these apparently useless processes are no doubt in certain cases as indispensable as is the much-abused middleman in matters economic. In a critical view of any case where similar results are aimed at by hand work and by mechanical means, it is important to recognise that the similarity of result should very seldom become identity. In the first machine, to do anything mechanically which has before been done by hand, the error is often made of trying to imitate the hand work rigorously. The first sewing machines were, I believe, made to stitch in the same way as a seamstress. It was not until a form of stitch suitable for a machine, although unsuitable for hand, was devised that the sewing machine proved successful as a practical matter.

I have endeavoured in my remarks to indicate what appears to me to be the attitude of the engineer towards a very large portion of the work which comes into his hands. In order to deal with the work it is necessary for him first of all to have a certain definite knowledge of "things"—that is to say, both of the various subjects which form part of the curricula of technical schools, and of the further matters which form as it were his professional alphabet. These last he learns not from books or lectures as a student, but by example and attempt, as does an artist. Of this part of his training I have said nothing ; it has been perhaps sufficiently talked about of late years, and there is little to say which I could have made interesting to a general gathering like this. I cannot leave it altogether, however, without dealing with one matter. Exceptional men are all-round mathematicians or physicists, still more exceptional men are both ; but for ordinary folk the study of one side of mathematics, or of a single branch of physics, is the work of a lifetime. The engineer is bound to know his own profession, by hypothesis, and it is in itself no small matter. Yet in addition he must know some mathematics, some physics, some chemistry, even also some geology, if he is to take any high rank in it. It is, therefore, surely in the very nature of things impossible that he should be a great mathematician or a great physicist, or should devote as much study to those most fascinating sciences as if they themselves were the work of his life. Therefore I beseech my friends of Section A to do what they can to modify their natural attitude of superiority—even of contempt—towards us, especially when we are students. The young engineer—I speak as a member of the great majority of the ordinary kind—would probably never have chosen his profession if he had had special aptitude for mathematical work. Having chosen it, he has to look at mathematics simply as a tool, a means to an end, not an end in itself. I cannot myself see that this point of view is one disrespectful to the parent of all the sciences, and I am confirmed by the knowledge that one or two of the greatest mathematicians in the country are of the same opinion, and have the courage to act on it—with infinitely beneficial results to the young men they have to deal with. But I know that to mathematicians in general—the physicists are not so bad—the very name of engineering student is odious, indicating only a man who wilfully refuses to make mathematics his "first subject," and who, therefore, deserves neither consideration nor quarter, to whom it is privilege sufficient that he should be allowed to pick up such crumbs as he can digest from a table prepared for his betters. I humbly protest that we deserve better treatment. It is no doubt a great misfortune to us that we cannot afford to spend our training time preparing for examinations, and that we have been compelled to choose for our future a career in which mathematics plays only a secondary part. It is our further misfortune that we have to solve 20 real live problems, each demanding a real live answer, for every single one which otherwise we would have worked out on paper. Perhaps it is also our misfortune—or it may be only our thickheadedness—to believe that in consequence of this we are quite able to judge for ourselves what units it is most convenient for us to work in, what nomenclature satisfies our requirements, and that we are as capable of getting our "g's" in their right places as even some of our distinguished critics. I venture to repeat here what I had lately an opportunity of saying before a Royal Commission—that in cases where a university or university college takes in hand the preparation of engineers—and I hope that such cases will grow in number—they should provide for them special training in mathematics, and probably also in physics, distinct from the general training in these subjects most suitable for degrees. I say this with the full knowledge that I may be accused of wishing to degrade the purity of scientific work, and at the same time with the full knowledge that I have no such wish. On the contrary, this special training is the only means by which the rank and file of us will ever know any mathematics at all. And I can say from my own knowledge that if only we can be made what I may call mathematically articulate beings, we shall be able to repay the kindness by placing before the man of pure science problem after problem of transcendent difficulty, of immense interest, and having no single drawback whatever except that its solution may really be "useful," and, after all, this need not be brought too prominently under his notice.

This digression has turned out a long one. I have only further to say that my main object in this address has been to indicate, as well as I could, the general attitude which the engineer must of necessity take up towards much of his work—the point of view from which he must look at it. I shall be extremely glad if anything which I have said should cause this attitude—this point of view—to be more clearly kept in mind in the period of training than probably has been hitherto the case.

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free 13s.

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS Price 12s. 6d. post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free. Also in German, 8s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free, 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING (1893). By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS Edited by W. W. BEAUMONT. Price 2s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

ELECTRIC MOTIVE POWER. By A. T. SNELL. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

PRACTICAL MAGNETISM. By J. A. KINGDON. [*In preparation.*

In Preparation. Very fully illustrated.

ELECTRIC LAMPS AND ELECTRIC LIGHTING.
Being Four Lectures delivered in April-May, 1894, before the Royal Institution, by Prof. J. A. FLEMING, M.A., D.Sc., F.R.S.

THE POST OFFICE AND THE NATIONAL TELEPHONE COMPANY.

In December, 1890, it became for the first time possible for the Government to purchase the telephone system of the country under the terms of the licences granted to the various telephone companies at work in the United Kingdom. Nothing, however, was done in the matter, and the opportunity then allowed to slip by will not again present itself until December, 1897. On May 27, 1892, there was laid on the table of the House a copy of a Treasury Minute which may without exaggeration be said to have announced a new era for telephony in this country. The lamb was to lie down with the lion; the Post Office and the National Telephone Company were to "co-operate in services to the public"; the former was to take over and work the trunk wires, the latter was to be given all manner of Post-Office assistance in the laudable and necessary task of improving its urban exchange system. On June 28th, a Bill giving the Post Office the needful authority to carry out the proposals of the Treasury received Royal Assent; and, on August 11th, heads of arrangement were signed by the parties concerned. To-day the public can purchase for the sum of 7½d. a mass of printed matter weighing, in London, something like half a pound, and containing, amongst other documents, a draft of the proposed agreement between the Postmaster-General and the National Telephone Company—a draft which certain members of Parliament seemed as if they would never be happy until they got it, and which, now they have it, they seem as if they never would be satisfied until they are rid of it. How it comes about that two years have been allowed to elapse between the signing of the preliminaries and the completion of the indenture, in which the two pages of the former were expanded into ten pages of legal verbiage, is not obvious on the surface, and it booteth not perhaps to inquire. The basis upon which the State was to purchase the trunk wires—viz., cost price thereof plus 10 per cent.—was settled on August 11, 1892, and though the exact delimitation of the exchange areas set forth in Schedule II. was doubtless a long business, there surely cannot have been any serious differences over a mere detail.

Digitized by Google

The purchase price, the main thing which concerns the public, now that it has assented—too readily, as we think—to the half-way house plan of the Post Office, cannot, one would imagine, give rise to much cavilling, even on the part of the most vigilant parliamentary guardian of the public purse. It is true that the cost of the National Company's trunk wires cannot be ascertained from its books, as originally proposed, but will have to be estimated by "two experts in telegraphic engineering." The alteration is not, however, of serious moment, and, this important point disposed of, the long-winded indenture may be taken as read.

A few of the matters of detail, on the other hand, are of some interest. The date on which the transfer of the trunk lines to the State is to take place, referred to with appropriate solemnity as "the appointed day," is fixed for July 1st next. A page is devoted to setting forth the terms upon which telephone wires belonging to one party are to be maintained by the other. The arrangements with regard to the connecting up of post offices with exchanges are characteristic of the complication which this half-baked scheme gives rise to. All such wires are to be erected and maintained by the Company at its own expense; the wires and apparatus actually within the post offices, however, are to be worked by the State at its own expense, and maintained by the State at the Company's expense. The Company, whilst paying the State nothing for its labour in working the apparatus, will have to pay it a rental for the use of the post offices; and so on, and so on. Better the devastating army of postal officials conjured up by Mr. GOSCHEN in his speech deprecating the addition of the telephone legion to the Post-Office forces than this mad medley.

SENSE OF PROPORTION IN ENGINEERING.

The interesting address delivered by Prof. KENNEDY before Section G of the British Association treats of the engineer as a critic. Literary critics are of some use to the community when they boil down the contents of a new book into a paragraph or two, and thus enable their readers to judge whether the volume is worth buying; and they amuse each other, when disinclined for this useful work, by writing essays, with the intent of showing how much more clever they are than the author of the book which is supposed to be before them. Dramatic, art and musical critics write, of course, only for each other and for their friends, and are of no use whatever. It is a relief, then, to find a critic who is not expected to write, nor even to express his views articulately. The word engineer conjures up inmost minds the vision of a dirty man who either manages or makes engines or other machinery, essentially a craftsman, and a professional engineer is considered to be one who merely superintends the constructive work of contractors. Prof. KENNEDY shows that his real work lies rather in the preliminary operation of deciding how any given problem shall be solved, than in the more active task of carrying it out. Too much attention is paid to theorising on ideal examples, in which the conditions are assumed at random with an utter disregard of practical experience; or, going to the other extreme, attempts are made to teach in the lecture room matters that can only be learned in the workshop. A knowledge of theory and of actual work at the bench is essential to the engineer, both for the design of any piece of work or for superintending its execution; but Prof. KENNEDY reminds us that before even the design is begun the engineer has first to make up his mind about the particular way in which the problem is to be solved, and he points out that the considerations are too complex to be dealt with mathematically, or even physically. There are half-a-dozen ways of solving any particular problem of engineering, and any one of these may be strictly in accordance with scientific theory and the best engineering practice; but probably only one of them is really the right one. At all events, only one, as a rule, can be put into execution.

The first act of an engineer, then, is to criticise and to select the course to be taken. Whether the choice is made from his own original designs, or those of his assistant, is mere detail. A good technical training can make a good draughtsman, and with mechanical instinct and electrical knowledge he could design a first-class dynamo, and might be competent to superintend its construction; but there his duties end. It is for the engineer to decide whether the machine is suitable for the particular conditions under consideration, and his is the responsibility for selecting it. But Prof. KENNEDY points out that not only in this important initial step is the engineer called upon to make up his mind, but throughout all the details of engineering work, even to the choice of the size of a bolt, he must act as a critic, and the very first necessity to such a critic is that he should have a sense of proportion. He rightly judges that although a student may be taught to criticise perfectly along certain very narrow lines, it is a doubtful point how far the student can be systematically imbued with a sense of proportion. Like invention, which of course cannot be taught, it seems to consist in the use of a vivid imagination. The engineer must picture to himself all the different solutions of the problem, and range them before his mind's eye, criticise them, and make his selection. An inventor creates but one mental image at a time, and as he studies it he finds one improvement after another to be necessary, and sees the image gradually change as each alteration is effected. But the engineer has to place a row of such images before him, and these not necessarily of his own creation. In many cases he is actually debarred from making a single alteration. He has to confine himself to weighing advantages against drawbacks. In electrical engineering further difficulties are introduced by the consideration of such matters as the fall of volts over a network of mains, the self-induction of a coil, and other quantities of a more abstract, or, at all events, less material nature than those which concern a mechanical engineer. The other matters discussed and briefly alluded to by Prof. KENNEDY are worthy of thoughtful study—the value of quantitative experiment and the relative importance of each measurement, the "worth-whileness of economies," the balancing of the activity of a machine against its vitality, the definition of "simplicity," and the use of mathematics. On any one of these we should like to have heard him enlarge.

LIST OF THE ELECTRICAL PAPERS READ AT THE BRITISH ASSOCIATION.

The following is a complete list of the electrical Papers read and reports presented at the Oxford Meeting of the British Association:—

SECTION A.

LORD KELVIN, P.R.S., MAGNUS MACLEAN, and ALEXANDER GALT.—"Preliminary Experiments to find if Substraction of Water from Air Electrifies it."

LORD KELVIN, P.R.S., and ALEXANDER GALT.—"Preliminary Experiments for Comparing the Discharge of a Leyden Jar through Different Branches of a Divided Channel."

PROF. O. J. LODGE, F.R.S.—"Photo-Electric Leakage."

PROF. O. J. LODGE, F.R.S.—"An Electrical Theory of Vision."

Digitized by Google

PROF. O. J. LODGE, F.R.S.—"Experiments Illustrating Clerk Maxwell's Theory of Light."

PROF. A. SCHUSTER, F.R.S.—"On a Suggested Explanation of the Secular Variation of Terrestrial Magnetism."

PROF. A. SCHUSTER, F.R.S.—"On the Construction of Delicate Galvanometers."

LORD RAYLEIGH, SEC.R.S.—"On the Minimum Current Audible in the Telephone."

LORD RAYLEIGH, SEC.R.S.—"An Attempt at a Quantitative Theory of the Telephone."

PROF. S. P. THOMPSON, F.R.S.—"On Mirrors of Magnetism."

PROF. C. G. KNOTT.—"On Volume-changes Accompanying Magnetisation in Nickel Tubes."

A. P. TROTTER —"On a Graphical Transformer."

H. STANSFIELD.—"On the Relation Between the Surrounding Gas and the Electrical Conductivity of thin Soap Films."

DR. ADOLPH SCHMIDT.—"On a New Analytical Representation of Terrestrial Magnetism."

FRANCIS G. BAILY.—"Note on the Hysteresis of Iron and Steel in a Rotating Magnetic Field."

PROF. J. J. THOMSON, F.R.S.—"On the Velocity of the Cathode Rays."

A. G. VERNON-HARCOURT, F.R.S.—"On a Ten-Candle Pentane Lamp."

DR. G. J. STONEY, F.R.S.—"How the misuse of the word 'Force,' in Attractions, Electricity, and Magnetism, may be avoided without much departure from existing practice."

DR. G. J. STONEY, F.R.S.—"On a Nomenclature for very much Facilitating the Use of Systematic Measures."

PROF. VIRIAMU JONES, F.R.S.—"Determination of the International Ohm in Absolute Measure."

PROF. VIRIAMU JONES, F.R.S.—"On Standards of Low Electrical Resistance."

R. T. GLAZEBROOK, F.R.S.—"Comparison with the B.A. Units of some Coils of Low Resistance."

J. RENNIE.—"Comparison of the Standards of the Board of Trade with the B.A Unit."

E. O. WALKER.—"Comparison of some Standards belonging to the Indian Government."

REV. T. C. FITZPATRICK.—"On the Specific Resistances of Copper and Silver."

J. TEICHMÜLLER.—"On the Specific Conductivity of Copper."

Report of the Electrical Standards Committee.

Discussion on Integrators, Harmonic Analysers and Integraphs, and their application to Physical and Engineering Problems. Opened by PROF. HENRICI, F.R.S.

SECTION B.

PROF. ROBERTS-AUSTEN, F.R.S.—"The Electrolysis of Glass."

Report of the Committee on Electrolytic methods of Quantitative Analysis.

Discussion on the Behaviour of Gases with regard to their Electrification and the Influence of Moisture on their Combination. PROF. J. J. THOMSON, F.R.S., showed experiments illustrating the connection between chemical change and electric discharge through gases.

SECTION G.

W. H. PREECE, F.R.S.—"Signalling through Space."

PROF. S. P. THOMPSON, F.R.S.—"Some Advantages of Alternate Currents."

T. PARKER.—"Continuous Current Distribution of Electricity at High Voltage, being a Description of the Lighting of the City of Oxford."

H. LEA.—"A Special Chronograph."

G. M. CLARK.—"A direct-reading Platinum Pyrometer."

SECTION I.

PROF. OLIVER LODGE, F.R.S., and PROF. GOTCH.—"Some Physiological Effects of the Passage of Rapidly Alternating Currents of Great Intensity through Nerve."

G. J. BURCH.—"On the Production with the Capillary Electrometer of Photographic Records of Currents Produced by Speaking with a Telephone."

Telephonic Communication between France and Switzerland.—An international telephone wire is at present in course of erection between Besançon, the centre of the French watchmaking industry, and the Swiss town, La Chaux-de-Fonds.

THE BRITISH ASSOCIATION AT OXFORD.

The proceedings of the sixty-fourth annual meeting of the British Association were inaugurated, on Wednesday evening last week, by the resignation of the presidential chair by Prof. Burdon Sanderson, and its assumption by the Most Honourable the Marquis of Salisbury. The presidential address was one having a many-sided interest. As a literary production it was full of terse epigram and eloquent diction. As a piece of scientific criticism from the standpoint of one whose intellectual abilities confer authority, but who confessedly stands outside the ranks of professional scientists, it demands the attention of every student of science. Physicists should be most thankful to Lord Salisbury for his frank, but perfectly justifiable, criticisms of modern atomic and ether theories. Particularly apt was his description of the ether as something "to furnish a nominative case of the verb 'to undulate.'" The sharpness of this epigram lies in its profound truth. Professional physicists are—or appear to be—content if they can refer every action to an undulation, and the medium of every action to this convenient "nominative case." But what Lord Salisbury and the rest of the intelligent world are asking is: Why undulation? Is there nothing further down than this verb 'to undulate,' with its phantom nominative case? Nor was the definition which Lord Salisbury gave to the word-labels which scientists fasten on certain sets of phenomena any less profoundly true and caustic. Physical science is not unacquainted with too many of "those indefinite words from time to time vouchsafed to humanity, which have the gift of alleviating so many perplexities and masking so many gaps in our knowledge." Time was, and not many years ago, when the major part of the map of Africa was labelled "desert." The ancients were more modest, and labelled their unexplored regions "*terra incognita.*" Many tracts of science would have their high-sounding labels removed and "*terra incognita*" substituted, if we were more willing to show the nakedness of our inward ignorance.

THURSDAY, AUGUST 9TH.

The sectional activities were commenced at various hours on Thursday, by the reading of the presidential addresses. Our readers will find in our columns the full text of the addresses before sections A and G. In the former section, Prof. Rücker directed the attention of his audience, and of the outside world, to the pressing needs of the science of terrestrial magnetism. The address was delivered in the large lecture theatre of the Museum, which was crowded to overflowing. The vote of thanks to the president was moved by Lord Kelvin, who emphasised the importance of reform in our national and international researches in terrestrial magnetism. Adjournment was then made to the lecture theatre of the Clarendon laboratory, the larger hall being required for the presidential address of another section. This smaller hall was quickly filled, the visitors included Lord Salisbury, who took great interest in the Papers which were read. The first Paper was on "Preliminary Experiments to find if Subtraction of Water from Air Electrifies It," and was read by Lord Kelvin, who occupied considerable time, and was at great pains to describe these researches. He commenced by mentioning several ways, such as by the friction of air blowing across a sandy desert, in which the atmosphere might possibly be electrified. He then described the apparatus employed by himself, together with Messrs. Maclean and Galt, to determine if the abstraction of water from air, *per se*, produced electrification. A lively debate ensued, the main point of discussion being the validity of the method of experiment. Prof. Quincke, of Heidelberg, considered that the observed electrification might possibly be accounted for by movement of the desiccating fluid in which the pumice was soaked. Prof. Lodge conceived that Lord Kelvin had attributed to condensation results which might wholly be accounted for by the friction of the air in its passage through the apparatus. Particles of dust carried over from the bellows would become electrified by friction against the indiarubber tube through which the

Digitized by Google

current of air was forced; and the particles of moisture in the midst of the lumps of pumice might similarly be affected. Prof. J. J. Thomson threw doubts on the validity of experiments made with air rushing through tubes. Prof. Fitzgerald suggested that any electrification due to chemical action by the drying agent could be prevented by cooling the apparatus to a sufficiently low temperature. Prof. S. P. Thompson observed, that if there was any doubt as to whether the evaporation of a substance caused its vapour to become electrified, that doubt ought to be dispelled by the fact that between the positive carbon and the vapour, in a voltaic arc, there was a pressure of some forty or fifty volts—a difference of potentials which could only be accounted for on the hypothesis of actual electrification by volatilisation. Prof. Schuster pointed out that in experiments of a highly complicated nature, like those with which Lord Kelvin and his colleagues had been dealing, the validity could only be established by a careful process of elimination, and that this was exactly what Lord Kelvin and his colleagues had done. That the use of one drying agent alone, or only one form of the experiment, would warrant a doubt as to the validity of the conclusion was admitted by all; but the experimenters had been careful, by using various desiccating substances, and by varying the form of the experiment, to eliminate every one of the special marks of reasonable doubt, and had left little or no doubt that the subtraction of water from air does electrify it. Lord Kelvin, in reply, said that Prof. Schuster was quite right.

The next Paper was on "Preliminary Experiments for Comparing the Discharge of a Leyden Jar through Different Branches of a Divided Channel," and described some researches recently carried out by Lord Kelvin and Mr. Galt. In the discussion, which was very feebly supported, Prof. Lodge gave a lucid and interesting account of his theory of the alternative path in condenser discharges, and explained why it is that an iron path has a greater damping effect than a copper one. The morning session concluded with a Paper, by Prof. Lodge, on "Photo-Electric Leakage," in which the experiments of Hertz, Lodge, Elster and Geitel on the effects of ultra-violet and polarised light in the diselectrification of positively and negatively electrified surfaces were described. These researches have recently been described in *The Electrician*. The meeting then adjourned for the purpose of making a complicated tour of the neighbourhood in search for lunch. Owing to the utterly inadequate arrangements, a large number of the visitors on arriving at the luncheon tent discovered that the provisions had been wholly consumed. Returning in a vacuous state to the lecture theatre, the members proceeded to a lively discussion on thermodynamical speculations. This discussion was opened by a report, by Mr. G. H. Bryan, on the present state of his knowledge in thermodynamics, and by the reading of two Papers on the dynamics of a gaseous system.

Friday, August 10th.

The focus of electrical interests shifted, on Friday, to section B, which is usually devoted to matters relating to chemistry. Readers of the B.A. "Journal" found, on Friday morning, that a "Discussion on the Behaviour of Gases with regard to their Electrification and the Influence of Moisture on their Combination," was arranged to take place in this section. Consequently, chemists and physicists, besides a goodly number of well-known electrical engineers, mustered in force, to the detriment—at least during the early forenoon—of the attendance at sections A and G, which had temporarily coalesced. The line of discussion was mapped out by three remarkable Papers, each dealing with one aspect of a yet unexplained phenomenon, viz., the physico-chemical action of moisture on gases. The first Paper was contributed by Prof. J. J. Thomson, of Cambridge; and dealt with the resistance to electrical stress of gases in various degrees of moisture. Prof. Thomson illustrated his remarks by showing a number of experiments. Various gases in a rarefied condition were subjected to rapidly alternating electric stress; and it was demonstrated that the effect of drying the gas was, in each case, enormously to increase the potential gradient required to cause a luminous discharge. One very conclusive experiment was that in which a pair of glass bulbs, connected by a tube of glass, had been filled with rarefied gas; the connecting tube was then closed under a blowpipe flame. One of the bulbs, which contained a desiccating agent, would not glow in the same alternating electrostatic field which caused the other to glow brightly. Adverting to the potential gradient required to produce electrolytic dissociation of a single isolated molecule of water, Prof. Thomson said that a potential gradient of 30 millions of volts per centimetre length was necessary. It was hopeless to try to produce this electric stress artificially. Where several molecules were present, the influence of each on its neighbours was sufficient to exert the necessary force; which is clearly an instance where union is *not* strength and power. The two succeeding Papers showed that, in certain cases at any rate, there is a parallel between the electrical and the chemical importance of aqueous moisture in gases. For it was experimentally demonstrated by Mr. H. B. Baker that the admixture of dry ammonia and hydrochloric acid gases resulted in no chemical change, whereas the least trace of moisture in the mixed gases led to the formation of dense white ammonium chloride. Many other examples of this "chemical happy family" were exhibited; substances possessing the most intense chemical "affinity" remaining quiescent if perfectly dry. The reading of these most interesting Papers, which, undoubtedly, deal with something quite on the borderland of physico-chemical knowledge, was followed by an informal and lively discussion. Prof. Schuster said that the facts were incontestible; but as to the electrical theories which had been based upon them he could not but raise a doubt. He laid great stress on the results of experiments which, he said, ought to be made on the rarefied vapour of mercury—an elementary, monatomic gas. Mr. Baker replied that a limitation must be placed on the inferences, in so far as they related to any substances which might dissociate into atomic states before the chemical or electrical effects were produced. Prof. J. J. Thomson admitted that his interpretation required the assumption that the atom of each element might be either positively or negatively charged in the same gas or mixture of gases. He also admitted that the general extension of his theory to phenomena at high temperatures (2,000° C., for example) would make it necessary to assume that "drops" of water—*i.e.*, aggregations of molecules of water—could exist under such conditions. The chemists, generally, who took part in the discussion were inclined to doubt the hypothesis of atomic charges and interatomic stresses. They were divided in their opinion as to whether the phenomena above described depended upon aqueous moisture, *per se*, or on a state of moisture, generally, which might be caused by various compounds.

Meanwhile, the combined sections, A and G, had been taking part in a discussion on "Integrators, Harmonic Analysers and Integraphs, and their Application to Physical and Engineering Problems." The discussion, which was very poorly attended, was opened by Prof. Henrici, who exhibited and remarked upon his own ingenious instruments. By the time the two discussions, that of A and G in Keble Hall and that of B in the Museum, were over, there had taken place a very considerable change in the "balance of power," at any rate numerically. For the prospect of a lively debate on so romantic a subject as "Flight" had drawn an immense audience within the walls of Keble Hall. The discussion was opened by a lengthy speech by Lord Kelvin on the resistance of solids moving through fluids. Mr. Maxim's communication describing his machine came next; after which Lord Rayleigh ventured to ask and reply to the question: What is a flying machine?

Saturday, August 11th.

Most of the sections met for shorter or longer periods on Saturday, but the Papers on electrical matters were at a low ebb. The large number of contributions to Section A made it necessary for this section to divide; one sub-section dealing with a list of some fifteen mathematical Papers, a second considering the reports of the various committees and some physical Papers, and a third dealing with Papers having a physico-chemical nature. The mathematical sub-section found it necessary to adjourn until Tuesday, owing to the heavy list of Papers. In the physical and report sub-section Prof. Osborne Reynolds showed an interesting series of experiments on the

Digitized by Google

boiling of water in an open vessel with a constricted tubular orifice. The character of the ebullition was shown to make four distinct critical changes as the temperature and pressure were raised. In the physico-chemical sub-section two electrical Papers were discussed; the one by Mr. H. Stansfield on "The Relation between the Surrounding Gases and the Electrical Conductivity of Thin Soap-Films," and the other by Mr. W. C. Dampier-Whetham on "The Velocity of the Hydrogen Ion through Solutions of Acetates." Meanwhile Section G had busied itself with three important Papers, including a Paper by Mr. B. Donkin on "The Most Economical Temperature for Steam-engine Cylinders."

MONDAY, AUGUST 13TH.

Whether to attend Keble College Hall, for the purpose of listening to a number of Papers on electrical engineering in Section G, or to cross over to the Clarendon Laboratory, where Section A had provided itself with a very long programme, consisting largely of electrical Papers, must have sorely puzzled the electrical individual who was anxious to make the best of his time on Monday. If his choice had fallen upon the engineering section, he would have spent the morning and the greater part of the afternoon in listening to two or three popular expositions from leading men, and he would probably have gone away with the impression that, though he had been mightily amused, he had heard little or nothing new and certainly nothing profound. Mr. Preece led off with a long Paper on "Signalling through Space," and the novice who had read his title must have wondered if it is possible to signal anywhere else but "through space." But what Mr. Preece had to say dealt with an inductive method of electrical signalling without metallic conduction between the sending and receiving stations. His Paper reviewed his researches in this method of signalling, and concluded with particulars of his most recent work on the subject, and some fanciful speculations on the possibility of signalling to Mars and other worlds than ours. It never seems to have occurred to the speculators on this topic that, even assuming the electrical possibility, there would be far less chance of being understood than if they were to signal to the polar bear at the Zoo. Mr. T. Parker's Paper on the system of electric lighting in use at Oxford received an effective fillip from the previous monologue on "Some Advantages of Alternating Currents," by Prof. S. P. Thompson. Indeed, this *pot pourri* of alternating-current information would otherwise have had little justification; but as the spicy criticisms of continuous-current practice, with especial reference to Oxford, which Prof. Thompson sprinkled over his Paper caused a lively counter-fire from Mr. Parker when his turn arrived, the audience had little cause to complain of the disconnectedness of the former Paper. Prof. Thompson's was, in fact, a typical B.A. Paper of the olden time—a number of slightly related facts grouped together beneath a sufficiently broad title; and it ranged from alternating electromagnets and motors to feeder regulation and the use of the "booster." To the adverse criticisms that were raised, Prof. Thompson made the obvious retort that his Paper was a piece of "special pleading"; and he gave one the impression that he could have made out quite as good a case had his subject been "Some Advantages of Continuous Currents." Mr. Parker's Paper described and gave some figures relating to the economy in the Oxford electric supply station, a full description of which will be found in *The Electrician*, Vol. XXIX., p. 254. At this station, the load factor for the previous year had been 5·69 per cent.; yet a coal consumption of only 6·38lb. per unit sold, costing but 0·718 penny, had been required. The energy, as metered, was only slightly over 100,000 units. A revenue of 10s. 11d. per 8-c.p. lamp had been obtained.

Had, however, the individual in quest of electrical lore elected to sit in Clarendon Laboratory, there is no doubt he would have been provided with more profound and tougher fare. Dr. A. Schmidt read a Paper on "A new Analytical Representation of Terrestrial Magnetism," which proved to be an extension of Gauss's expression enabling the internal and external components of the terrestrial force to be expanded in separate terms. Prof. Schmidt made the hypothetical assumption that an element of the force arose from an electrical displacement amounting to one-tenth of an ampere per square kilometre of surface. Prof. Schuster next read a Paper on a "Suggested Explanation of Secular Variations of Terrestrial Magnetism," which will be found in our columns this week. He showed that since the assumption either of infinite or of zero resistance of inter-planetary space led to no dissipation of energy, there must be a certain degree of conductivity at which, if the space possessed it, the dissipation and consequent retarding force would be a maximum. The maximum possible retardation, on the assumptions made by Prof. Schuster, would be so very gradual that it would be very difficult, if not impossible, to dissociate the effect from that of other retarding forces. Prof. Schuster also read a Paper giving some comparisons between the sensitiveness of galvanometers with various forms of coil-winding. In a Paper "On the Minimum Current audible in the Telephone," Lord Rayleigh showed that the degree of sensitiveness depends on the nearness of the frequency of the impulses to the natural periods of vibration in the disc, the greatest sensitiveness being obtained when the frequency of impulse was identical with the natural frequency of vibration. A number of other Papers were also read, the subjects being chiefly of minor electrical interest.

TUESDAY, AUGUST 14TH.

The climax of electrical interest was undoubtedly reached on Tuesday, when a joint discussion on theories of vision, by the physical and physiological sections, was inaugurated by some brilliant experiments and two memorable Papers by Prof. Lodge. The large lecture theatre of the museum was crowded to overflowing, among the audience there being a large number of distinguished physicists and physiologists. The proceedings commenced with a Paper by Prof. Lodge in connection with some "Experiments illustrating Clerk Maxwell's Theory of Light," in which the quasi-optical properties of electromagnetic radiation were very beautifully, very carefully, and very convincingly demonstrated. This Paper was really the prologue to the Paper on "An Electrical Theory of Vision," which immediately followed, and its direct purpose was to initiate the physiologists into the researches of Hertz, Lodge and others on this quasi-optical behaviour of electromagnetic waves. Prof. Lodge, in his second Paper, disclaimed the intention of advancing a "theory" of vision, and urged that his communication was rather in the nature of a question put to physiologists as to whether it is possible that anything resembling the action of electro-magnetic waves on a coherer could be supposed to take place in the vertebrate eye. It was difficult to know which to admire most, whether the carefully logical manner in which Prof. Lodge arranged the facts, or the modesty with which he advanced his hypothetical deductions. The gist of Prof. Lodge's hypothesis is, that a simple electric circuit consisting of a coherer contact and an otherwise closed circuit—with or without a seat of electromotive force—may be taken as an analogue, and may, *ex hypothesi*, be an enlarged model of the mechanism of vision. Just as a galvanometer in the coherer circuit will, if there is an electromotive force, be affected by electro-magnetic stimuli acting on the coherer, so the mechanism of vision may be supposed to be affected by the stimuli of optical rays. Each element of the retina—each rod and each cone—must, on this assumption, be taken as consisting of a coherer circuit which can transmit its individual impulse to the brain. The author then showed that there were two positive but opposite stimuli required, if the analogy was to be made complete. Not only was an optical stimulus necessary in order to enable the eye to perceive the element of light which falls on it; but a cancelling stimulus from within the organism was required in order to enable the eye *not* to see the visual impression when the luminous source was removed from its gaze. A coherer circuit once affected by an electromagnetic wave has a tendency to persist in its lessened resistance and increased current; and it requires some mechanical stimulus to jerk the coherer contact back to its normal state of badness. Prof. Lodge showed by an experiment that it was quite possible to limit the "persistence of vision" of the coherer circuit by arranging that the coherer should be mechanically tapped in rapid succession. The conclusion of Prof. Lodge's Paper was received with hearty and prolonged applause. In the discussion which

Digitized by Google

followed, Lord Rayleigh, after congratulating Prof. Lodge on the ingenuity of his hypothesis, made the remark to the Physiological Section, that physicists could object neither to the Young-Helmholtz theory nor to that of Henry, provided that three *independent* variables in the system of equations was granted. There might be six variables in all, three dependent and three independent; but whatever hypothesis might be advanced, no explanation of vision could be recognised which did not postulate these three independent variables.

Prof. Burdon-Sanderson made an excellent speech, in which he said that physiologists could perceive no inherent objection to the hypothesis of Dr. Lodge; but, he said, it was useless to advance any theory of the action of the complex stimuli of vision which did not also apply to the more simple stimuli met with in other organs and in tissue of plants and animals generally. There were a number of "touch and go" stimuli, and the stimulus of the retina by mechanical means was one, where the action was functionally precisely the same as that of light on the retina. Prof. Schäfer pointed out that the vertebrate eye had a number of filamentary processes which might possibly represent a coherer; but, he added, the phenomena of vision were not confined to the vertebrate eye, but were also found in invertebrates, where a complicated retina and quasi-coherer processes were not to be found. A number of other leading physiologists added their support to the view that the morphology of the vertebrate eye very strikingly fell in with Prof. Lodge's hypothesis of a coherer circuit. Prof. Armstrong proposed that the true hypothesis of vision must account for the chemical actions which occur when light falls on the retina, and suggested that the chemical actions were the primary, and the electrical actions the secondary, cause of vision.

The section was now divided, and one portion was occupied with Papers on optics. The other division debated on Papers relating to electrical standards. Mr. R. T. Glazebrook read the formal report of the Committee on Electrical Standards. Prof. Viriamu Jones communicated the results of a "Determination of the International Ohm in Absolute Measure." Lord Rayleigh said that no method previously used for finding the ohm could compete in point of accuracy with that used by Prof. Jones.

Across the road, the engineering section had been taking a number of important Papers. The valuable report of the Committee on Dryness of Steam was submitted by Prof. Unwin, who described the work which had been done in the perfection of methods of measuring the dryness factor of steam. A useful Paper on "The Hunting of Governed Engines," by Mr. J. Swinburne, was next considered; after which a number of Papers of general engineering interest were discussed.

WEDNESDAY, AUGUST 15TH.

The publication of the *Journal* on Wednesday morning was the herald of the anti-climax. In that convenient newspaper it was announced, in respect of no less than five out of the nine sections, that "This section does not meet." Even the four sections which did meet on Wednesday, provided themselves with short programmes, and got through them as quickly as possible in order to attend a University function at the Sheldonian Theatre. This function had to do with the conferring of a number of honorary degrees upon distinguised scientists and others. In section A, five Papers were announced to be read; but as the only electrical Paper, viz., that by Prof. Newall, "On the Spectra of Discharges in Gases Without Electrodes," was withdrawn, the electrical interest in the proceedings of this section fell to zero with an impulsive rush. In the physiological section two interesting electrical Papers were read; one by Profs. Lodge and Gotch on "Some Physiological Effects of the Passage of Rapidly Alternating Currents of Great Intensity through Nerve," and the other by Mr. G. J. Burch "On the Production with the Capillary Electrometer of Photographic Records of Currents Produced by Speaking with a Telephone." The Oxford meeting of the Association terminated at the concluding general meeting which was held at half-past two, when the Association adjourned till next year when it meets at Ipswich.

The Oxford meeting of the British Association has been one on which its members may congratulate themselves; for a very much larger amount of solid, useful work and of valuable interchange of ideas has taken place, than is usual. The presence of so many distinguished scientists, both from all parts of the kingdom and from abroad, has contributed most effectively to the intellectual and educational success of the meeting. Some idea of the week's work may be gathered from the fact that no less than 384 Papers and Reports have been presented during the six days of sectional session; the number of Papers read before Section A being 80, and before Section G only 23. A striking feature of the Oxford meeting has been the number of discussions by temporarily conjoined sections; and section A, to give one example, has derived profit from its coalescence with the physiologists on Tuesday, as well as from its union with the engineers on Friday. Other sections have largely adopted this most efficient method of inducing brotherly love and catholic thought, and we trust it will be even more extensively adopted at future meetings.

By far the largest number of Papers, in any single section, was read in Section A, which may also fairly claim to have done the greatest amount of work, and to have sat for the longest time. Indeed, the pressure of work in this section has been so great that, with the instinct of a Barnum and the ambition of a Kiralfy, the section has provided a number of simultaneous side-shows, a practice which has made it quite impossible for the individual member to hear more than about one-half of the Papers. Possibly the claim to the cream of the session may justly be made by the Chemical Section, in which the chief sensation was the announcement by Lord Rayleigh and Prof. Ramsay of the discovery of a hitherto unsuspected substance in the earth's atmosphere, a substance which till recently has been confused with nitrogen, which it greatly resembles. The chemists naturally hastened to find a seat for this substance at Mendeljeef's table, if only it can show a clear claim to be considered an element.

But the British Association has done something else than serious work; it has enjoyed a full measure of recreation. The fun has even brimmed over, and leaked into the Papers and into the discussions. Mr. Swinburne's sporting Paper on "The Hunting of Governed Engines" is an example; and none the less so was the cruel fun in which Mr. Preece seems to have been indulging of driving sirens—he does not say they are not Homeric sirens—"at first slowly, then increased until a 'screech' is produced, then again dying away." Yet, after such severe treatment as this, Mr. Preece seems to evince great surprise that, do what he would, he could never get the creatures to "screech" again—after the "dying away"! A Paper on the significance of ticklishness, which was read before the anthropological section, must have showed a desire to obtain a scientific theory for all this jocularity; and the companion one on "Shoe-throwing at Weddings" showed how the British Association would rather have its joke than its man. The literature of the "new humour" must have been in the mind of the author of the communication on "The Effect of Gravity on the Circulation"; and the report of the Committee on Erratic Blocks should induce publishers to be careful that the blocks on one side of a page do not by accident improperly co-ordinate with those on the opposite side. Finally, people who have dropped into adverse circumstances may derive a crumb of comfort from "The Philosophy of Holes."

A SUGGESTED EXPLANATION OF THE SECULAR VARIATION OF TERRESTRIAL MAGNETISM.*

BY ARTHUR SCHUSTER, F.R.S.

It is a matter of great importance to ascertain whether we must consider interplanetary space to be a conductor of electricity or not. If there is an appreciable conductivity the magnetic system of the earth will, owing to its rotation, induce currents which will react on the earth in a twofold manner. There will be, in the first place, a mechanical effect tending to

* Paper read before the British Association at Oxford, Section A.

Digitized by Google

increase the length of the day, and, secondly, a magnetic effect tending to displace the magnetic axis. It is the object of this communication to give the results of some numerical calculations referring to the magnitude and nature of these reactions.

The problem is of interest apart from any applications to terrestrial magnetism. Given a magnetic sphere rotating in a conducting medium, what are the mechanical and magnetic forces acting on the sphere in consequence of electric currents induced in the medium?

The mathematical solution is easily obtained from Lamb's equations for currents induced in spherical conductors; and, without entering into any details of calculation, I here state the principal results for the case that the sphere is uniformly magnetised about an axis not coinciding with the axis of rotation.

If the medium is either perfectly conducting or perfectly non-conducting, there will be no mechanical effect tending to stop the rotation of the sphere; but for all finite conductivities there will be a couple opposing the rotation, which is a maximum for a certain specific resistance of the medium.

If the radius of the sphere is R, the angular velocity ω, the specific resistance ρ producing the maximum retardation is given by the relation

$$\rho = 1{\cdot}4\, R^2 \omega,$$

where the numerical factor is approximate only.

For the earth: $R = 6{\cdot}4 \times 10^8$ $\omega = 7{\cdot}27 \times 10^{-5}$

$$\rho = 4{\cdot}7 \times 10^{13}.$$

The resistance indicated by this number is such that if 4·7 volts were applied to the two sides of a plate having a thickness of one centimetre there would be a current of 10^{-4} amperes per square centimetre. I do not know of any facts which would make such a conductivity an impossible one, consistently with the extreme tenuity of matter which we know must exist in space. The next point to consider is the actual value of the maximum retarding couple. In C.G.S. units, and for a sphere having the same size and magnetic moment of the earth, it is $1{\cdot}9 \times 10^{24}$. If this couple was to act continuously it would diminish the earth's rotational velocity to the extent of one second per day in 14,000 years. Early records of solar eclipses show that the earth as a timekeeper has lost time, but authorities do not agree as to how much. Two causes tending to alter the length of the day have hitherto been considered, tidal friction tending to retard it, and the contraction of the earth tending to increase it. To this we must now add a possible retardation due to the conductivity of the medium.

The maximum magnetic couple calculated above is about six times that given by George Darwin for the effect of tidal friction, and it would by itself have produced a very marked effect in historical times. But, as far as I know, we have no data giving us any information as to the allowable contraction of the earth. If the diminution of the earth's radius amounts to a foot a century, it would counterbalance the maximum effect which the magnetic couple could possibly have. It is, of course, very improbable that the conductivity of space is just that required for the maximum effect. If the conductivity is 100 times less, the couple produced would be equal to the tenth part of the maximum couple, and such a couple would be impossible to separate at present from the other effects, tending to alter the length of the day. There is, therefore, a very large range of electric conductivity, within which that of space may lie without an appreciable effect on the length of the day being produced in historical times.

Turning our attention next to the magnetic reactions, we find that these will displace the magnetic axis towards the geographical pole and round it from east to west. If the earth behaved like a steel sphere, not subjected to any shocks or changes of temperature, a certain displacement would take place once for all, but no rotation such as is required to produce the secular variation. The constantly-renewed displacement of the magnetic axis, if it is due to the suggested cause, must be produced by a continuous change inside the earth. A possible explanation suggests itself in the secular cooling of the earth, owing to which more and more of its iron becomes susceptible to magnetisation. This virgin iron will be free to adjust its magnetic axis to the magnetic forces acting on it, and a continuous displacement of the axis must result. It must be acknowledged, however, that even taking account of this possibility it is difficult to see how a rotation of the axis can be kept up for several revolutions. Some light might be thrown on the question by an experimental investigation to discover a possible effect of great pressure on the temperature at which iron loses its magnetic properties.

If the secular variation is connected with the conductivity of space, everything that affects the latter must affect the rate of progress of the variation. I have on several occasions expressed an opinion that the curious effect on the earth of an increased sun-spot activity may be due to a greater electric conductivity at times of many sun-spots. When the above explanation occurred to me two years ago I looked up the records to see whether that secular variation seemed to proceed more rapidly when the sun-spot activity was great. I found, indeed, some remarkable coincidence between the years in which the secular variation was great and marked sun-spot years; but on the whole the parallelism of the two phenomena did not seem sufficient to draw public attention to the fact. Recently, however, I found the same coincidence noticed independently (I believe by Liznar). Should it prove established on further investigation the theory of the secular variation suggested above would deserve attention. Whether there are any appreciable magnetic effects due to electric currents outside the earth may, of course, be established by an analysis of the magnetic forces on the surface of the earth. I understand that A. Schmidt and Neumayer have already made much progress with such an analysis, and I am preparing an independent calculation with special reference to the outside forces.

The results of this investigation may be stated thus:

(1) The mechanical reactions on the earth of currents induced in space, assumed to be a conductor of electricity by the rotation of its magnetic system, are insufficient to produce an appreciable lengthening of the day in historical times, unless the conductivity lies within certain narrow limits. The absence of any marked effect cannot, therefore, be brought forward as an argument against the conductivity of space.

(2) The magnetic reactions of the same current, taken in conjunction with the secular cooling of masses of iron inside the earth, tend to produce a displacement which in kind is the same as that actually observed in the secular variation. But whether quantitatively the variation can be explained in this way is very doubtful.

SIGNALLING THROUGH SPACE.*

BY W. H. PREECE, C.B., F.R.S.

Whenever an electric current rises or falls in a circuit another current is simultaneously induced in every neighbouring conductor, if it form part of a circuit and be separated from the former by some insulating medium or dielectric, such as air. This secondary current flows only during the period of rise or of fall of the primary current.

Hence, if the primary current rises, falls, or changes its direction regularly and repeatedly a given number of times per second, the induced secondary currents will alternate with the same regularity and frequency. The intensity of these secondary or induced currents, among other things, will depend upon the character, form, and direction of the circuits, and upon the distance which separates them from each other. That such secondary currents, or electro-magnetic disturbances, as they are called, existed has, of course, been known since the days of Faraday; but that they could be observed, measured, and utilised at a distance of some miles from the primary circuit was not suspected before the introduction of that marvelous sensitive instrument the telephone.

When these disturbances are rhythmic, musical sounds are produced in telephones fixed in the secondary circuits, but when they are irregular unpleasant noises alone are heard. If the sounds are preconcerted and directed, like the dots and dashes of the Morse code, then telegraphy is possible, and we have a means of signalling through space without wires. The

* Paper read before the British Association at Oxford, Section G.

Digitized by Google

distance to which we can signal is limited only by the distance to which these electro-magnetic disturbances, in their transit through space, retain sufficient energy to actuate our apparatus, the ether is supposed to be the real medium of transmission, and not the air. The disturbances through the ether take the form of undulations or waves, and in character they are similar to those radiations which at other frequencies give us heat, light, and photography. They move with the same velocity; they are subject to the same operations of reflection and refraction; and they differ only in the number excited per second.

Thus, to deal with the subject of signalling through space, we must have a primary conductor, in which vibrating or alternating electric currents can be excited at will. They must alternate with a frequency that will pleasantly affect the ear—say about 600 per second. They must be manipulated so as to produce preconcerted signals. The primary circuit must be freely exposed in the ether; and the secondary circuit, which it is desired to excite, must not be screened from the primary by means of magnetic or conducting matter. The object of this inquiry has been to determine the best form of primary and secondary circuit, the function performed by the earth as a part of the circuit, and the distance to which communication is possible with the ordinary practical means at our disposal.

The telephone as an instrument of precision is scarcely sufficiently appreciated. The ear can be trained by its aid to measure graduations of sound as accurately as the eye determines the calibrations of engraved scales. In Hughes' induction balance we have a well-determined absolute zero of silence, and there are many well-defined nodes of sound which may be taken as fiducial points in a telephonic scale. The limit of speech where articulate sounds cease to be comprehensible is one, the limit of Morse signals where telegraphic reading becomes impossible is another. It is quite easy to determine the similar intensity of two sounds, as in photometry the eye determines the similar intensity of two illuminations. The ear, however, requires to be educated, and it is subject to fatigue; but when properly trained, and when assisted by the telephone, it can be used to observe effects with as much reliability as the eye.

My attention was first directed to the subject in 1884. In 1886 I brought it before this Association at Birmingham, and again at Manchester in 1887. In August, 1893, I reviewed, before the Electrical Congress at Chicago, the whole of my previous nine years' work. Much experimental work has been done during the past twelve months. In 1884 electromagnetic disturbances were detected between telegraph circuits and telephone circuits 80ft. apart, the former in the streets underground in London, and the latter on the housetops; but in 1885 these effects were perceptible between parallel lines of telegraph $10\frac{1}{2}$ miles apart. The permeability of stone walls and buildings to electric waves was shown by Henry in 1842, when the discharges of a Leyden jar in the top floor of his house induced sparks in a circuit in the cellar. Sonorous vibrations were reproduced in a telephone circuit in the basement of the G.P.O. in 1886 by the induction of a primary circuit excited by the voice in the upper corridor, 80ft. away. Speech was found possible between insulated coils of wire a quarter of a mile apart. Telegrams in 1893 were transmitted across a distance of 3.1 miles on the Bristol Channel. Regular communication was held last winter across Loch Ness, a distance of $1\frac{1}{4}$ miles, and recently at a much greater distance, between Arran and Kintyre, across Kilbrannan Sound. Across Loch Ness speech was maintained.

But this is not all. There is every reason to believe that we have detected distinct disturbances in our telegraphic circuits due to great electrical storms in the sun's photospere 92,000,000 miles away.

The fact that these signals across space are effects of induction, transmitted through the air or the ether as the dielectric, is beyond the region of doubt, for they were produced between isolated and insulated coils, each forming a complete metallic circuit; but the part played by the earth at short distances when the earth was used to complete the circuit was not so clear. Very exhaustive experiments were made on the sands in the Conway estuary in 1893, and again at Frodsham on the estuary of the Dee in 1894. These experiments were conducted for me by Mr. Gavey and Mr. H. R. Kempe. Further experiments were made by Mr. Gavey and Mr. Cooper on opposite sides of Loch Ness, a distances of $1\frac{1}{4}$ miles, and between the Island of Arran and Kintyre, where parallel wires four and five miles apart were available for use.

In the Conway estuary and at Frodsham squares and rectangles were formed of insulated wires, and numerous measurements were made, both with reflecting galvanometers and with telephones, of the effects due to varying currents in the primaries, and at varying distances between these and the secondaries.

At Loch Ness two parallel wires on opposite sides of the Loch were taken. Between Arran and Kintyre (Fig. 1) two parallel lines on opposite sides of the Sound, and four miles apart, were taken; and, in addition, two gutta-percha wires were laid along each coast at a height of 500ft. above the sea level, and five miles apart horizontally.

The general results and the conclusions arrived at may be briefly summed up as follows :—

The earth acts simply as a conductor, and *per se* it is a very poor conductor, deriving its conducting property principally, and often solely, from the moisture it contains. On the other hand, the resistance of the "earth" between the two earth

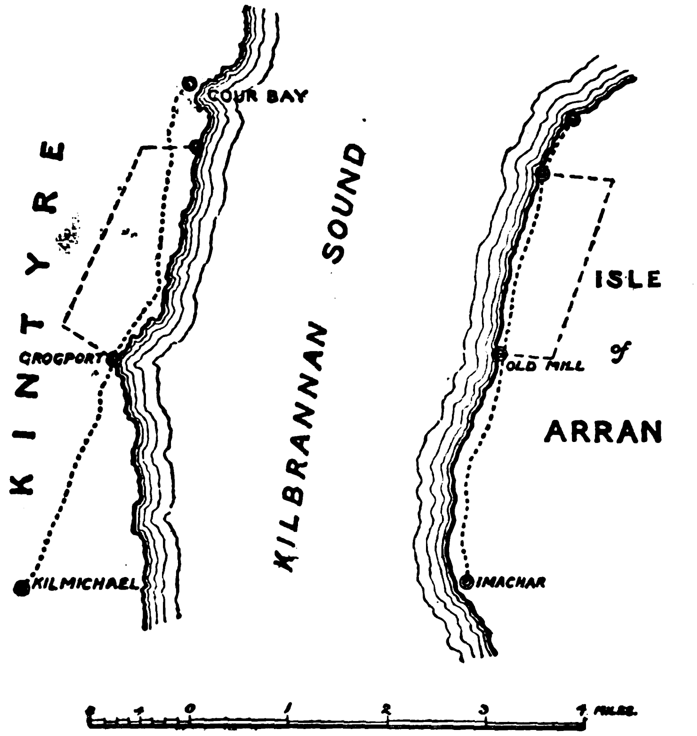

FIG. 1.

plates of a good circuit is practically nothing. Hence it follows that the mass of earth which forms the return portion of a circuit must be very great, for we know by Ohm's law that the resistance of a circuit increases with its specific resistance and length, and diminishes with its sectional area. Now, if the material forming the "earth" portion of the circuit were, like the sea, homogeneous, the current-flow between the earth plates would follow innumerable but definite stream lines, which, if traced and plotted out, would form a hemispheroid. These lines of current have been traced and measured. A horizontal plan on the surface of the earth is of the form illustrated in Fig. 2, while a vertical section through the earth is of the form shown in Fig. 3.

With earth plates 1,200 yards apart these currents have been found on the surface at a distance of half a mile behind each plate; and, in a line joining the two transversely, they are evident at a similar distance at right angles to this line.

Now this hemispheroidal mass could be replaced electrically by a resultant conductor (R, Fig. 3) of a definite form and position; and, in considering the inductive action between two circuits having earth returns, it is necessary to estimate the position of this imaginary conductor. This was the object of the experiments at Frodsham.

Digitized by Google

If the material of the earth be variable and dry the hemispheroid must become very much deformed and the section very irregular, the lines of current-flow must spread out further, but the principle is the same, and there must be a resultant return. The general result of the experiments at Frodsham indicate that the depth of the resultant earth was 300ft., while those at Conway are comparable with a depth of 350ft.* In the case of Frodsham the primary coil had a length of 300ft., while at Conway the length was 1,320ft., At Loch Ness and between Arran and Kintyre, where the parallel lines varied from two to four miles, the calculated depth was found to be about 900ft. The depth of this resultant must, therefore, increase with the distance separating the earth plates, and this renders it possible to communicate by induction from parallel wires over much longer distances than would otherwise be possible.

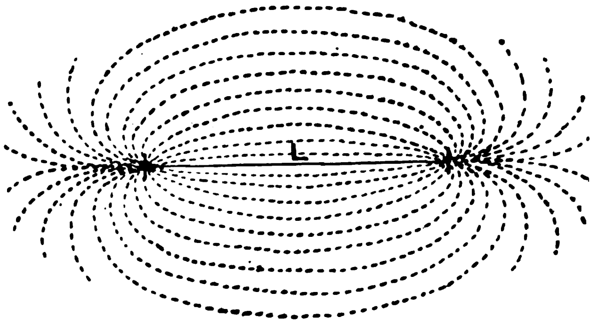

FIG. 2.

The first and obvious mode of communicating across space is by means of coils of wire opposed to each other in the way familiar to us through the researches of Henry and Faraday. All my illustrations of the principles involved in effecting this object have consisted in opposing two similar coils of wire having many turns, the one coil forming the primary current and the other coil the secondary circuit.

Vibratory or alternating currents of considerable frequency were sent through the primary circuit, and the induced secondary currents were detected by the sound or note they made on a telephone fixed in the secondary circuit.

The distance to which the effective field formed by a coil extends increases with the diameter of the coil more than with the number of turns of wire upon it. A single wire stretched across the surface of the earth, forming part of a circuit completed by the earth, is a single coil, of which the lower part is

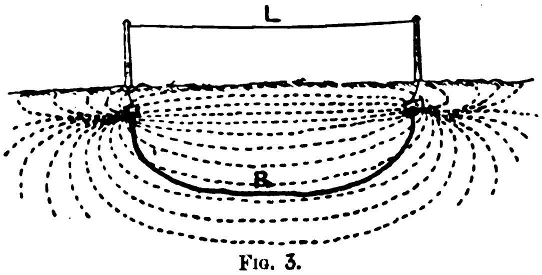

FIG. 3.

formed by the resultant earth return, and the distance to which its influence extends depends upon the height of the wire above the ground, and the depth of this resultant earth.

In establishing communication by means of induction there are three dispositions of circuit available, viz., (*a*) single parallel wires to earth at each extremity; (*b*) parallel coils of one or more turns; (*c*) coils of one or more turns placed horizontally and in the same plane.

The best practical results are obtained with the first arrangement, more especially if the conformation of the earth admits of the wires being carried to a considerable height above the sea, whilst the earth plates are at the sea level. By adopting this course the size of the coil is practically enlarged, and even if it be necessary to increase the distance between the parallel wires to effect this object the result is still more beneficial. In a single wire circuit we have the full effect of electrostatic and electro-magnetic induction, as well as the benefit of any earth conduction, but in closed coils we have only the electro-magnetic effects to utilise.

In one experiment two wires of a definite length were first made up into two coils forming metallic circuits, then uncoiled and joined up as straight lines opposed to each other, with the circuit completed by earth. The inductive effects, and the distance between which they were observable, was very many times greater with the latter than with the former arrangement.

Incidentally some extremely interesting effects of electro-magnetic resonance were observed during the experiments in Arran. A metallic circuit was formed partly of the insulated wire 500ft. above the sea level, and partly of an ordinary line wire, the rectangle being two miles long and 500ft. high. Wires on neighbouring poles, at right angles to the shorter side of the rectangle, *although disconnected at both ends*, took up the vibrations, and it was possible to read all that was signalled on a telephone placed midway in the disconnected circuit.

I have not succeeded in determining satisfactorily the general law which regulates the distance to which one can speak, and I scarcely hope to do so. There are so many disturbing elements introduced, geological as well as electrical. In practice we have to deal with two complete circuits of unknown shape and in different planes. We have obtained some remarkably concordant and accurate results in one locality, but we have met with equally discordant results in another locality. I fear we are beyond the reach of the mathematician. In the appendix I have shown the formulæ that gave the most reliable results.

The mechanism of the mode of signalling across space is not difficult to follow. Its analogue is a flash of light seen at a distance. Energy is expended, say, in a lighthouse on some dangerous rock, or in a gun firing some warning signal, or in a bonfire on some mountain top. The energy assumes the luminous form exciting the ether to undulate with a frequency of many millions per second, which, acting upon the retina of the eye, produce the sensation called light. The burning of the oil-lamp of the lighthouse is the primary source of energy; the rapid undulations of the ether propagated in straight lines at a velocity of 186,000 miles per second are the radiations, transmitting this energy in a wave form to the distant ship; the eye is the apparatus which transforms the energy of the light-waves into a form which excites consciousness in the brain.

In our electrical experiments the primary energy is in the current form, the comparatively few alternations per second excite waves in the ether of a few hundreds per second only. But these oscillations of the ether or electric waves are of the same character as those of light, they move with the same velocity, and when they fall on a sympathetic secondary conductor, they excite in that conductor currents of electricity of the same frequency; and if a telephone be inserted in that circuit and applied to the ear, sounds and musical notes are distinctly heard which by preconcerted measures, such as the use of the Morse code, can be utilised for the transmission of messages. Thus messages were sent across the Bristol Channel between Penarth and Flat Holm Island, 3·1 miles away. Speech was maintained in the Highlands across Loch Ness, 1¼ miles broad, and telegrams were transmitted from Kintyre to Arran, across distances of four and five miles, and thus we could readily communicate between England and France, or between outlying islands and the shore, when the conditions admit of the erection of the necessary circuits.

A somewhat fascinating branch of this subject is the possibility of signalling across planetary space. Signalling between one planet and another is merely a question of degree. Magnetic storms and earth currents have some intimate connection with the sun, although Lord Kelvin has questioned the reality of the fact The great storms and sun spots of March 30 and 31, 1894, were accompanied by very marked and peculiar sounds in telephones inserted in our long telegraph circuits (*v.* Appendix II.) The storm of July 20th was not so distinguished Strange, mysterious, weirdlike sounds are frequently heard on long lines of telegraph in the calm stillness of the night, but whether due to terrestrial or to cosmic causes remains to be discovered

* These figures are obtained from the use of the formula $Q = K\left\{\log\left(\frac{D^2}{d^2}+l\right)\right\}$ which is given in Appendix I.

Digitized by Google

The sun's photosphere when disturbed by spots may be subject to violent electrical storms and those vast crouds of incandescent hydrogen that flame up with terrible velocity may excite electrical oscillations through etherial space of such a frequency as to influence our terrestrial circuits. We may thus hear on earth the electric storms of the sun. But this is mere speculation, and the evidence before us at present is not sufficient to justify positive deduction. We shall continue to watch and record, and it is hoped that observers in other parts of the world will assist by making use of the telephones and telegraph lines at their disposal.

The practicability of this method of effecting communication is now solved, but the subject possesses great scientific interest from the views it imparts of the mechanical character of electrical waves, of the molecular theory of electricity and of the great distances at which electromagnetic disturbances are perceptible.

Appendix I.

The following are the formulæ on which the foregoing calculations are based :—

Let A B (*a*) (Fig. 4) be an infinitely long wire, and *b* and *c* be two wires forming parallel sides of a rectangular circuit,

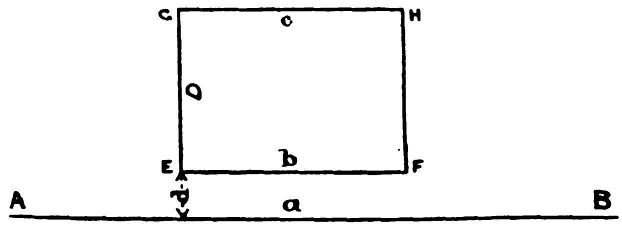

Fig. 4.

E F G H; then, if a current be set up in A B, the lines of force cutting E F and G H will cause a momentary current to be set up in the rectangle, so that

$$Q = K\{\log(D+d) - \log d\} = K \log \frac{D+d}{d},$$

where Q is the quantity induced.

K is a constant depending on the length of the sides G H, E F of the rectangle in centimetres, the current strength in amperes in the wire A B, and the total resistance in ohms of the rectangle.

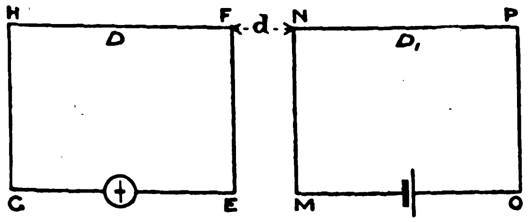

Fig. 5.

Within certain limits this formula is approximately correct, even if the wire A B is not infinitely long, but makes one face of a second rectangle similar in form to the induced rectangle E F G H, and set either in the same plane with, or at right angles to, the first rectangle ; but in such cases the formula has to be corrected to allow for the influence of the second face of the inducing rectangle as follows :—

With two rectangles in the same plane (Fig. 5) the total effect produced by the two faces, M N, O P, of the inducing rectangle is

$$Q_1 = K\left\{\log\frac{D+d}{d} - \log\frac{D_1+d+D}{D_1+d}\right\}.$$

If the two rectangles are at right angles to each other (Fig. 6) and l is large compared with D, then the formula becomes

$$Q_2 = K\left\{\log\frac{D+d}{d} - \tfrac{1}{2}\log\frac{D_1^2+(D+d)^2}{D_1^2+d^2}\right\}.$$

Again, if the two rectangles are parallel and equal (Fig. 7) and l is large compared with D, then

$$Q_3 = K\left\{\log\left(\frac{D^2}{d^2}+l\right)\right\}.$$

These formulæ take into account the effects on the wires in the secondaries which are parallel to the primaries, but not the effects of those at right angles to them. The latter oppose the

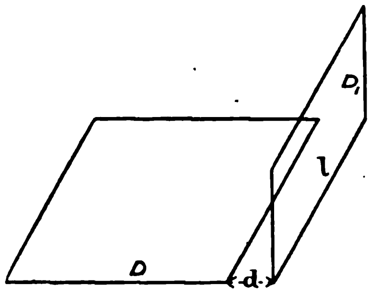

Fig. 6.

main induced current, so that in practice this current diminishes more rapidly with the distance than the log law indicates.

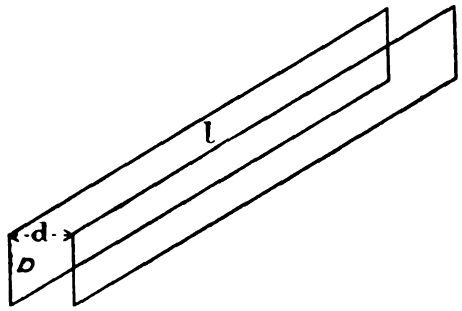

Fig. 7.

The problem is very intricate, but Mr. Kempe, to whom I am indebted for the formulæ, still hopes to obtain a final and accurate solution.

Appendix II.

The following letter appeared in *Nature*, April 12, 1894 :—

Earth Currents.

The Astronomer Royal was kind enough to show me the permanent photographic records of earth currents during the great magnetic storm on February 20th-21st, and they indicated so unmistakably such rapid and violent alternations, that I supplied our principal relay stations with telephones and with instructions to insert them in circuit whenever they observed indications of disturbances. This happened on March 30th-31st, during the display of the Aurora Borealis. Mr. Donnithorne, in Llanfair P.G., Anglesea, reports :—" At 2:0 a.m. (Saturday) the telephone receiver was again tried, and then 'twangs' were heard as if stretched wire had been struck, and a kind of whistling sound. The strength of the earth current was 17·7 milliamperes." Mr. Miles, in Lowestoft, reports :—" Noise on 408 (Liverpool-Hamburg) wire seemed like that heard when a fly-wheel is rapidly revolving," and " sounds in telephone appear like heavy carts rumbling in the distance." Mr. Scaife, in Haverfordwest, reports : " March 31st, 2:5 a.m. Earth currents on all wires ; wires completely stopped. . . . Peculiar and weird sounds distinctly perceived, some highly-pitched, musical notes, others resembling murmur of waves on a distant beach. . . . The musical sounds would very much resemble those emitted by a number of sirens driven at first slowly, then increased until a 'screech' is produced, then again dying away. Duration of each averaged about 20 seconds." These experienced observers, situated at three distant points, and perfectly acquainted with the ordinary inductive disturbances on telephone circuits, simultaneously observed and independently recorded their own impressions of peculiar sounds exerted in telephones by very rapid alternations or pulsations of currents which accompanied, or were consequent on, sun spots, earth currents, and the Aurora Borealis.

W. H. Preece.

G.P.O., April 9th.

A GRAPHICAL TRANSFORMER.*

BY A. P. TROTTER.

This instrument is intended for the expeditious re-plotting of a curve with transformed ordinates without calculation or scaling. It consists of a rectangular frame and a curved template or cam, and is used in conjunction with a straight ruler.

Let the scale of one system of ordinates be set off upwards along the edge of one of the perpendiculars, and the scale of

* Paper read before the British Association at Oxford, Section A.

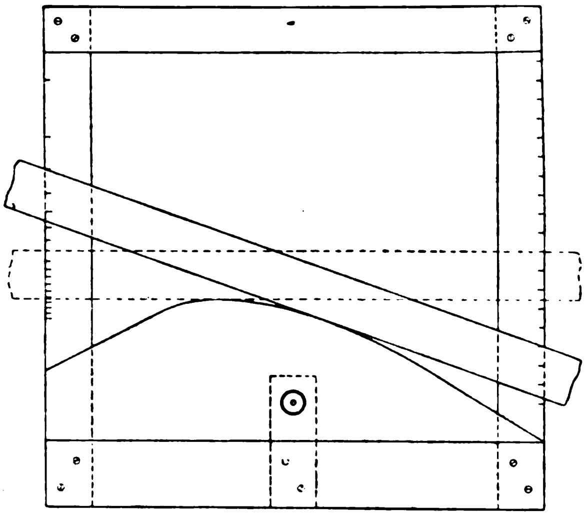
Digitized by Google

the other along the edge of the other perpendicular, but downwards. Join the corresponding points on the scale by straight lines. The envelope of this system of lines may be thus drawn, and to this curve a cam is cut in thin wood or ebonite.

To transform any ordinate, set the frame against a T square, adjusting the edge to the ordinate, and the zero to the zero of the scale. Set a needle at the extremity of the ordinate; bring a straight edge to touch the needle and the cam; prick off a point at the intersection of the straight edge with the other edge of the frame. This point determines the length of the new ordinate.

The illustration represents an instrument provided with a logarithmic cam. With this instrument the product or quotient of two curves can be found by adding or subtracting the logarithms of the ordinates; or the logarithms of a series of observations can be plotted. Cams for other functions can be easily made; but it must be remembered that the action of the instrument is, as it were, arithmetical rather than geometrical, for a cam is useful only with reference to its own scale.

This instrument not only enables transformations of a definite and known character to be made, but is equally applicable for transforming in an empirical manner. The curve drawn by a



recording voltmeter or ammeter may thus be re-plotted for estimation of area, or other graphical analysis, without any knowledge of the law of the particular instrument. In other words, a correction can be applied to a curve.

The cams are easy to make, and even if carelessly cut, cannot possibly give rise to cumulative errors. It is convenient to use the upper edge of the ruler instead of the edge which rolls on the cam. The curve must in this case be set out with the ruler, and used with the same ruler, or one of the same width. The rolling of a straight edge on a cam has been used in a photometer, invented by Mr. W. H. Preece and the author,* for the automatic calculation of the squares of the displacements of a lamp.

THE FRENCH PRESS AND THE BRITISH SUBMARINE TELEGRAPH COMPANIES.

[Communicated].

The French Press has again started, with the view of raising the national spirit in favour of French submarine cables, an agitation which is looked upon as the forerunner of applications to the Government for subsidies to assist the French telegraph companies in distress. Nothing need have been said about it had not the promoters of that campaign thought proper to attempt to strengthen their case by unfounded statements as regards the action of several English telegraph companies. The *Journal des Débats* took the lead in the matter in publishing a series of articles signed "Harry Allis," purporting to correctly state the present position of submarine telegraph matters in France, which, besides many unjustifiable assertions, contains certain charges against some English companies in their past and present relations with France, obviously put forward with the purpose of prejudicing the French Government and public against them. The following corrections show that these statements have no foundation whatever.

In the first place, it is impossible to accept the opinion that there is no country geographically situated under such favourable conditions to be the centre of telegraphic communications between Europe and America, as France; and it only requires a look at the chart of the Atlantic Ocean, to recognise that France is situated at a much greater distance from the American islands or the American shore, than Ireland or the point of Cornwall, involving, as a consequence, the use of longer and more costly cables, with a lower speed of transmission, as is shown by the respective lengths of 2,717 and 2,281 nautical miles of the existing two cables between Brest and St. Pierre, compared with the 1,847 miles length of the Anglo-American cable just laid between Valentia and Heart's Content. Nor has experience shown that this southern route is more free from accidents and interruptions. If, moreover, due account be taken of the fact that the proportion accruing to France proper in the telegraph traffic between Europe and North America is only 12 per cent. of the whole, whilst Great Britain's proportion is 61 per cent., the statement that one of the Atlantic companies ever intended to land in France their two original cables, is seen to be wholly unsupported by reliable evidence.

The part which relates to French concessions granted to English companies suggests the following observations and refutations: The concessions referred to for the 1883 Senegal cable was given to Count d'Oksza, who sold it for a consideration to an English Company. The same has practically happened as regards the contract of 1885 for the French possessions of Rio Nunez, Grand Bassam, Porto-Novo and Gaboon. At all events, it does not concern in any way the African Direct Telegraph Company, whose cables are only worked under an English contract and land only in British or Portuguese territories. But it is mainly in respect of the two contracts made with the Eastern and Eastern Extension Companies, that the charges proffered in the articles referred to assume an obviously prejudiced character. As regards the concession of 1883 for the Tonquin cable, it is not true that the Eastern Extension Company's cable between Hong Kong and Cochin China was out of order, and that it has since been superseded by the Tonquin cable for the Company's service. That cable, after ten years' service, since then elapsed, is still in good working order, and performing all the Company's service. Moreover, it is absolutely untrue that the cable used for Tonquin was "*en détresse*," and previously made for Japan. The cable was quite new, and expressly constructed in execution of the contract. The Government subsidy to the Company amounts to £10,600 per annum; but the proceeds of the local traffic between Cochin China and Tonquin belongs to the French Administration, which fact the writer judged proper to pass over in silence, and that traffic has now so much increased that it entirely fills up the capacity of the cable, which has thereby become of hardly any use for the Company.

Respecting the Obock cable, a similar denial must be unconditionally given to the statement that the cable was an old one which the Company had for several years carried about in their repairing ships. It was a new cable expressly manufactured in execution of the contract, which fact can be clearly established by documents of undoubted authenticity. It is not in this way that the Eastern and its associated Companies could build up the world-wide reputation which they undoubtedly possess.

As regards subsidies, there is no common sense in the mode of calculating them by summing up the yearly amounts for the whole duration of the contracts, without taking into account maintenance and repairing expenses, nor the fair proportion chargeable in respect of each cable to the expenses of the respective repairing ships, which are kept in readiness to re-establish the communication whenever interrupted.

The yearly annual cost of maintaining submarine lines depends not only on the length of a cable, but also on the risk of interruption and facilities of repairs; it will, therefore, be easily

* *Proc.* Inst. Civ. Eng., Vol. CX., p. 81.

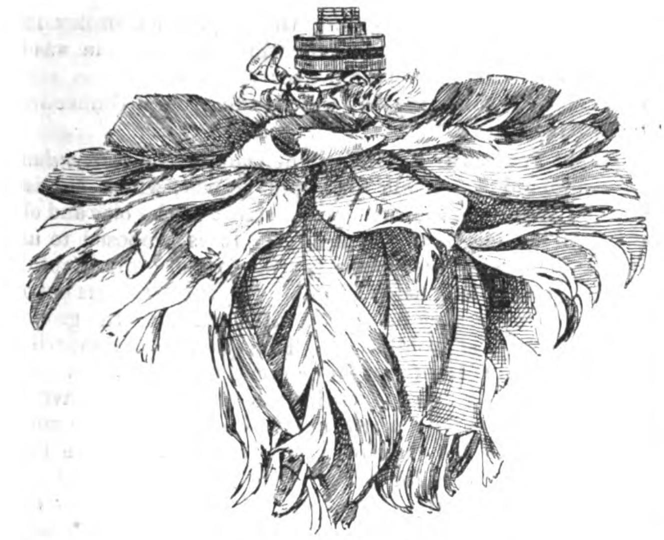
Digitized by Google

understood, for instance, that in the case of a short cable like that to Obock, laid across the Straits of Bab-el-Mandeb, where accidents to cables and interruptions are of almost daily occurrence and where expeditions for repairs are so costly, the subsidy of 37,500fr. is not out of proportion to the length and position of the cable.

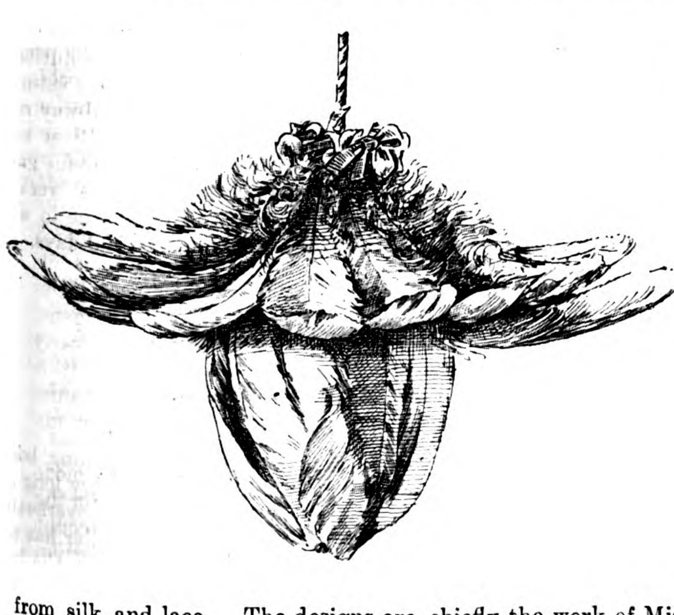
As a conclusion, it may safely be asserted that both Companies have every reason to believe that the French Government is quite satisfied with the terms of the above contracts and the way they are carried out. Also that there is good reason to assume that, owing to the increased cost of submarine telegraph lines, neither could now be contracted for on as good or better terms.

NOVEL LAMP SHADES.

Some pretty feather lamp and candle shades, for use with the electric light, are being introduced. The shades are composed of a specially-selected description of natural feathers



dried in various shades of colour, and arranged in artistic shapes and combinations, both of colour and design. The effect made by these shades is quite different to that obtained



from silk and lace. The designs are chiefly the work of Miss Beatrice Devonport, who has done the work for the Plume Company, for whom Messrs. Chas. Ingle and Co., of High Holborn, London, W.C. are the wholesale agents for the United Kingdom.

SHALL WE COME TO THE DOUBLE TROLLEY AT LAST?*

BY NELSON W. PERRY.

Much has been said and written of the damage done to underground conduits by electrolytic corrosion, and many have been the remedies proposed. Without doubt the most important Paper on this subject thus far has been that by Mr. I. H. Farnham, read before the American Institute of Electrical Engineers.† Certainly the damage that has been done by this agency has been far more extensive than appears at present, for in most cases it has only been discovered when it has become so extensive as to require the digging up of the pipes where they have been almost totally corroded through. It was years before this corrosion was discovered at all, and it may yet be years before its full extent will be realised in the almost total destruction of our water and gas mains. No one, I take it, will assume that this insidious enemy has confined its operations to the localities where its work has been discovered, nor will anyone probably believe that its mere discovery has stopped its work. It is certainly going on now, for instance, all over Brooklyn, though its action has been so slow or the time so short that little damage has as yet been disclosed.

The remedies that have been suggested from time to time, though they seemed to have worked well in some cases, have signally failed in others, and even when a success has been claimed it has not infrequently happened that the claimant was mistaken and that a failure was recorded instead of a success. Mr. Farnham, in his very exhaustive and carefully prepared Paper, for instance, claimed that the method adopted in Boston, that mare's nest of experiments, the evil had been practically remedied, and he was certainly honest in his claims, and his reasoning appealed to his audience as logical. The writer, however, has had a long interview with a former employé of high rank, of the West End road, who views the situation through entirely different spectacles. This gentleman was certainly qualified to speak, as he was one of those connected with the attempt of his Company to control the earth currents from its lines. His statement was to the effect that whatever remedy was tried seemed merely temporary and local, the effect being to drive the demon elsewhere. He estimated that the West End road had probably put quite as much copper underground as it had overhead, and still the trouble continued. Of course, if the electrolytic action were practically stopped at one point and removed to another or distributed over a greater area, it might take years to make itself manifest in those new areas; but the conclusion he comes to is that at best the trouble is only mitigated.

Now here is the testimony of two reputable men who contradict each other. That does not imply dishonesty on the part of either, for we well know that two reputable witnesses of the same event often contradict each other on material points.

Much faith is pinned to the welded rail as a panacea for the evil of electrolysis, but it has not been proved that the welded rail is practicable. There are strong hopes that it will prove so, but in the only extensive experiments thus far tried, viz., those in Johnstown and Boston, the rails have failed to withstand the contractions due to the rigours of winter. In both cases the rails stretched and stretched until they could stretch no longer, and then they broke. In Boston the breaks numbered about 6 per cent. of the welds. That is to say, that when winter had come on there were about 10½ breaks to the mile—absolute breaks which were worse than a faulty bond. Other experiments are now under way on a very large scale, but both of these have yet to stand the winter, and if they withstand the stretching of 4ft. or 5ft. to the mile, which would be due to the average decrease of temperature, they will still have to withstand the following summer heat, which may mean buckling and warping to such an extent as to require the relaying of the track. The question of whether or not the continuous rail is practicable cannot be definitely settled until more than a year from this date; but supposing, as I sincerely hope, it will pass both ordeals safely, the trouble from electrolysis is still not settled. Its evils would, doubtless, be mitigated, but not eradicated. We are too apt to think, and the statement has frequently been carelessly made, that electricity will follow the easiest path. This is not true. It will divide itself up among *all* the paths to which it has access in proportion to the conductivity of those paths.

A 70lb. rail has about the same conductivity as a copper conductor of 1,000,000 cir. mils (0·8 sq. in.), and the two rails will be the equivalent of 2,000,000 cir. mils, probably a far greater carrying capacity than the combined feeders to the trolley wire. They could, therefore, easily carry far more current than the feeders, and would at first sight seem to be ample for the return, and so they would be if they were insulated, but they are not and cannot be. Supposing we should lay alongside of these another

*From the *Street Railway Gazette.*

†See *The Electrician*, May 4, p. 16, and June 1, p. 134.

Digitized by Google

conductor of equal capacity, the rails would part with half their current, and this would still be true if the conductivity of the rail were tenfold what it was, providing that the parallel conductor were increased tenfold also. Now the gas and water mains, especially the latter, have a much greater conductivity usually than even the heaviest rails that are laid, and the resistance of the earth between two parallel conductors continuing parallel for such distances as the track and pipes often do, becomes almost negligible, so that the two must necessarily divide the current between them, and, notwithstanding every precaution of bonding or welding of the rails, the pipes may still carry even the greater portion of the current.

This course of reasoning—and it is correct electrically—would seem to indicate that all attempts to prevent electrolysis while the rail is used as a return must be abortive. The only alternative left seems to be to keep the current away from the rails entirely—to use the double trolley. There is a popular prejudice against the double trolley which it does not wholly deserve, for, in fact, in many respects it is superior to the single trolley, and it certainly does not cost any more than the latter when the earth return is properly provided for. The double trolley is scarcely known outside of Cincinnati—in fact, I do not know of a single instance of a road thus equipped in any other city, but there it reigns almost supreme. With something like 200 miles of road electrically equipped there is but one road, consisting of about four miles of double track, that uses the single-trolley system. Probably part of the prejudice against the double trolley originated in the early experience in Cincinnati. In the first place, the manufacturers discouraged it, knowing that it would be more difficult to get consents of property holders to the stringing of two wires over a track than one. In this they were right, and they feared to let it get a foothold, lest in its being insisted upon in subsequent franchises their own business would be injured. It cost about one-third more than the single trolley as roads were constructed then. They wanted to make about 200 per cent. profit on their equipments, and if they put up the double trolley the cost would be prohibitive if they still insisted upon the usual profit. So for this and other reasons no electrical company could be found, except the Daft, which was then on its last legs, that would erect a double-trolley equipment at any price. They would sell the apparatus, however, and let the railroad company put it up as it chose. The Cincinnati Street Railway Company being closely allied, through its stock holders, with the local telephone company, decided upon the double trolley as a protection to the telephone service. They therefore bought apparatus from the Thomson-Houston Company, and erected it themselves on about 3½ miles of their road. Having started with the double trolley, all extensions were of necessity constructed in the same way, and so with the connecting lines crossing the river to Covington and Newport.

The first double trolley consisted of a single mast arm forked at the top, having a trolley wheel on the end of each fork. The wires were stretched 18in. apart, and this trolley worked particularly badly going around curves, on account of the radii of the curves that had to be described by the two wheels. In fact it worked badly everywhere, and gave the double trolley a black eye at once. Two distinct masts, each similar to those now used on the single-trolley roads, were substituted, and with this change and some change in the overhead structure, the system worked well, and works well to-day.

During a lawsuit brought by the telephone company against the single-trolley road to compel it to cease interfering with its service, the single-trolley road attempted to prove that it could not operate with the double trolley. The double-trolley road was called in to prove that it was really the better system. Among other questions that arose was the relative expense of operating by the single and double trolleys, and both companies were obliged to bring their books into court. A comparison showed that the double trolley was operated at less expense than the single trolley, the reason being, as we know now, that the former had at all times as good a return circuit as the outgoing, while with the single trolley the ground return was a very uncertain quantity.

The greatest objection to the double trolley lies in the complications in the switches and cross-overs. This trouble is both mechanical and electrical. When two roads cross each other there is difficulty in insulating the positive from the negative, since in this system they must necessarily cross each other, whereas in the single trolley the two crossing wires are both positive and presumably at the same potential. In the double trolley, too, at a crossing there are *four* intersections, whereas in the single trolley there is but one. It is also evidently more difficult to insulate the positive and negative sides of the circuit when they are but 12 or 13 inches apart, as in the double trolley, than when they are so far separated, as in the single trolley; but, as an offset to this, the cars on the double trolley are entirely independent of the condition of the track, since it forms no part of the circuit. As a result of all this the double trolley in suburban districts where it does not intersect other wires has proved itself superior to the single trolley, but in centres where many lines cross and radiate it is at a great disadvantage, both on account of the mechanical and of the electrical difficulties attendant upon the many intersections. These difficulties are not insuperable, however, as in Cincinnati there is one centre—the intersection of two streets—Fifth and Broadway, where two lines run east and west, two run north and south, and there are four curves connecting these four lines together, and on Fountain-square the situation is still more complicated, yet these are the busiest car centres in the city. The complication of wires—trolley wires, span wires and pull-off wires—at these points is most unsightly and greatly to be deplored. A perfect stream of cars, however, is continually passing these points, and doing it apparently without trouble. But the water and gas mains are safe, and I believe this is the only way to make them so. There may be other partial remedies which will postpone the day of reckoning, but this seems to be the only radical cure.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 6, 1894.

Strikers and Trolley Lines.—The Electric Street Railway in Youngstown, O., for some time has been having trouble with strikers, which resulted in the road being tied up several times, the last expedient adopted by the strikers to this end being a novel one. During the night the trolley line was grounded, and the manner in which it was done was so skilfully concealed that traffic over the system was suspended until late the following day before the ground connection could be discovered.

Rapid Transit in Boston.—The people, by a *referendum* vote, have adopted a scheme for rapid transit, which consists of a subway under the most congested street of the city and elevated railways leading from the termini. It is proposed to use electricity for the motive power in the former; but Capt. Meigs, whose system has been adopted for the latter, is opposed to the use of electricity on the elevated roads on the ground that its cost would be prohibitive. The question submitted to the people was the Meigs system or none, though it has never yet been practically tried. Owing to the great disfavour with which underground electric systems are viewed by politicians on account of the lack of spoils, the people were given no opportunity to vote for it.

Chicago Exhibition Wire Tests.—The results of tests by four professors on commercial electric insulated wires have been published, only three of ten wires tested receiving favourable reports. The tests were of three kinds—a breakdown test, with an alternating current of high pressure, and two soaking tests, in one of which a current of 6,000 volts pressure was sent through the wire until the insulation broke down. Chicago hydrant water and four solutions were used in the two latter, two of which were 10 per cent. solutions of sulphuric acid and ammonia respectively, another a saturated lime-water solution, and the fifth a solution of subway refuse or scrapings from Chicago subways and Chicago River water. The samples of wire, equivalent to No. 16 Birmingham gauge, with $\frac{3}{32}$in. insulation, were tested at least once a week for resistance. In the simple soaking test the least time in which the insulation showed serious deterioration was 100 days.

CORRESPONDENCE.

THE MAXIM BOILER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Some years ago I made a very rapid steaming boiler, exceedingly light and effective. The tubes were very long and thin, and in order to prevent them from becoming overheated, I employed a forced circulation of water. This boiler has now been in use for some years, and there never has been the least thing happen to it. The boiler without any casing, burner or smoke stack weighs about 800lb., and on many occasions it has been made to develop more than 350 H.P. It is still intact.

A scientific gentleman—Mr. Pilcher—in speaking of the remarkable performance of this boiler before the meeting of

Digitized by Google

the Naval Architects, described the means which I employed for preventing the tubes from overheating by a forced circulation, and he said that *without* this forced circulation it was found that the tubes would overheat. As a matter of fact someone who has since made a similar boiler without the forced circulation did find that the tubes became overheated, and were ruined.

In the last number of *The Electrician*, however, you make Mr. Pilcher say exactly the reverse of what he really did say. Is this fair?—Yours, &c., HIRAM S. MAXIM.

August 9, 1894.

[The discussion was reprinted on p. 396 of our issue of August 3rd as it was reported. We regret that the report should have been inaccurate.—ED. *E.*].

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have just seen your issue of August 3rd, and your account of the discussion which took place on Mr. Thornycroft's Paper read before the Institute of Naval Architects. You have reported me to have said precisely what I did not say. I said that Mr. Maxim, by using a forced circulation in his boiler, obtained by the feed-water squirting down the downtake leg with considerable force, through a specially-constructed valve, had succeeded in being able to force his boiler to an extraordinary extent without overheating the tubes; but that he was of opinion that he would not be able to force the boiler nearly so hard without this forced circulation.

I shall be much obliged if you will publish this letter.—Yours, &c., PERCY S. PILCHER.

August 11, 1894.

FLY-WHEEL ACCUMULATORS FOR ELECTRIC TRACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As the question of employing high-speed flywheels as accumulators of energy for electric traction has been raised in your columns by Mr. Archibald Sharp, perhaps I may be allowed to point out that in Vol. CXII. of the *Proceedings* of the Institution of Civil Engineers for June, 1893, in the correspondence on Dr. E. Hopkinson's Paper on the South London Railway, I called attention to this very point, and suggested the advantage of employing for traction purposes engines of the steam turbine type, running, say, at about 4,000 revolutions per minute, fitted with solid cylinder fly-wheels, say 3ft. diameter and 3ft. wide, and weighing about six tons.

A single fly-wheel of this description would store sufficient energy to maintain 66 H.P. for two minutes with a 5 per cent. variation in speed, and, of course, a proportionally greater horse-power when the periods of variation between the maximum and minimum loads were less than two minutes, or, again, where a larger variation in speed than 5 per cent. was permissible.

A 3ft. wheel, running at 4,000 revolutions per minute, would have a peripheral speed of about 666ft. per second, but if of solid steel, would, I believe, be quite safe, as I understand that considerably higher speeds are actually used with the similar fly-wheels employed for propelling the Howell torpedo. In any case, absolute safety could be obtained by employing several wheels of smaller diameter arranged all upon the same axis.

No properly-designed hydraulic power system is nowadays constructed without its accumulator, and, the conditions as to rapidly-varying load with very short periods of maximum demand being analogous, it seems that plants for electric traction, as also perhaps those for electric welding, should be similarly equipped. For these, high-speed fly-wheels on the engines or dynamos seem to be the most convenient arrangement for this purpose.—Yours, &c., A. A. C. SWINTON.

66, Victoria-street, S.W., August 11, 1894.

LEGAL INTELLIGENCE.

Edison-Bell Phonograph Corporation (Limited) v. Smith and Mansfield.

In the Chancery Division, Mr. Moulton, Q.C., applied on behalf of the plaintiff Company for an injunction to restrain the defendants from infringing the plaintiffs' rights in a phonograph patent. His clients wanted some protection. This was a serious matter, and there were altogether about thirty actions. His clients had issued writs, because they believed they had established their patent, and if they did not take this course it might be a point of objection. It was even now pressed upon them that they did not deserve an interim injunction because they knew of the infringement, and did not bring the action sooner. His Lordship said he thought he ought not to make any order beyond this, that this action be consolidated with the other, and both to come on together. The motion would stand over accordingly, the costs to be costs in the action.

Edison-Bell Phonograph Company (Limited) v. M'Kinnon.

In the Court of Session, Edinburgh, Lord Trayner sat to hear an application by the Edison-Bell Phonograph Company (Limited), of London, to have David M'Kinnon, of Kilmarnock, interdicted from infringing letters patent which the complainers hold. The complainers averred that the respondent was at present using and exhibiting machines or apparatus which constituted an infringement of their patent. In reply, the respondent stated that the patent was invalid, in respect that it was not new at the date of the patent, especially in regard to the use of wax and the method of engraving or cutting records. He also averred that the invention which forms the subject of the patent was anticipated as regards all the claims, in respect that it was published by an article in a French periodical called *La Nature*, dated May, 1879, and subsequently by the publication in an issue of *Engineering*, dated April 18, 1879, of an article entitled "A Sixpenny Phonograph"; by the publication in *The English Mechanic*, April 25, 1879, of an article entitled "A Sixpenny Phonograph"; by the British specifications of Edison's patents published in 1878 in the Patent Office Library; by the U.S.A. specification of a patent by Christopher C. Reynolds in 1883, published in the Patent Office Library; and by the U.S.A. specification of another Edison patent published in the British Patent Office in 1879. The respondent also averred that the complainers had frequently applied in an English Court for interdict against the users of phonographs or apparatus similar to those described in the specification, but had failed to obtain such interdict or injunction, these having been uniformly refused, and in actions which were still in dependence the validity of the petition was being seriously disputed. The respondent's agent undertook that an exact account would be kept of all gains and profits derived from the use or exhibition of the machines.

His Lordship refused an interim interdict.

Alabaster v. Harness.

Mr. Justice Hawkins gave judgment on Friday last in this action. Plaintiffs are the proprietors of the *Electrical Review*, and defendant was manager of the Medical Battery Company. Plaintiffs were successful in an action which was brought against them by Dr. Tibbits for libel; but they were unable to recover their costs, and they now sued Mr. Harness, alleging that he was really maintaining Tibbits in his action.

His Lordship, in summing up, said that it was contended for the defendant that such maintenance was not unlawful nor actionable, inasmuch as he had a common interest with Dr. Tibbits in bringing it, or at least that he honestly believed, on reasonable grounds, that he had such interest. Light was thrown upon the circumstances under which maintenance becomes innocent by certain paragraphs in "Hawkins's Pleas of the Crown" dealing with acts of charity, mere neighbourly acts, and cases of "common interest." It could not be seriously suggested that the maintenance of Mr. Harness was due to a neighbourly or charitable spirit. There remained, therefore, the question whether Mr. Harness had, or upon reasonable grounds believed that he had, a common interest with Dr. Tibbits in the result of his action. Many cases were to be found in which persons have been held justified in contributing to the expenses of suits brought or defended by others with the object of defending or enforcing a common right in which all were interested; but there was no case in which a person has been held justified in maintaining a suit in which he was not interested in "the thing in variance," nor any in which such a claim of common interest as this has been even suggested. In this case the article complained of Dr. Tibbits contained also libellous imputations upon Harness and his institute, but these did not form any part of the cause of action, nor was there any issue as to his character or conduct. In the action brought by the Medical Battery Company against Alabaster and others, the defendant Harness had a full opportunity of completely vindicating not only the character of the Company, but his own. That action he abandoned some months before Tibbits's action was tried, preferring to shelter himself under the wing of Tibbits. By acting as he did the defendant saved himself from liability as to the then defendant's costs, and he (the learned Judge) was of opinion that he merely availed himself of Tibbits's action to save himself from the risk of liability for the then defendant's costs; and that his conduct in all these respects was unlawful. The verdict must be entered for the plaintiffs for the amount of the taxed costs of their defence as between party and party.

Stay of execution was granted in view of an appeal, but only on condition that the defendant paid into Court the £500 which was claimed.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Dundee Gas Commissioners invite tenders for the supply of a steam engine and dynamo machine in connection with their electric supply scheme. Copies of the specification and form of tender can be obtained of Messrs. Urquhart and Small, 17, Victoria-street, Westminster, S.W., to whom tenders must be sent on or before Thursday, the 30th inst. Some further particulars appear in our advertisement columns.

TENDERS ACCEPTED.—The Electric Lighting Committee of the Cheltenham Town Council have received nine tenders for transformers as follows :—

Brush Company	£394	15	0
Crompton and Co.	450	0	0
Electric Construction Company	455	10	0
Johnson and Phillips	468	0	0
Slade, Templeton and Co.	500	0	0
Swinburne and Co.	522	0	0
C. A. Parsons and Co.	606	12	0
Siemens Bros. and Co.	677	0	0
John Fowler and Co.	783	5	0

On the recommendation of the Council's electrician the Brush Company's tender was accepted. The report of the Committee containing these figures was adopted at the last meeting of the Council.

SALES BY AUCTION.—The important sale of plant and machinery by Messrs. Fuller, Horsey, Sons and Cassell, at the works of Messrs. Latimer Clark, Muirhead and Co., Regency-street, Westminster, which was announced to be held on Tuesday, Wednesday, and Thursday, the 4th, 5th, and 6th prox., has been extended to four days, *i.e.*, Tuesday, Wednesday, Thursday, and Friday, the 4th, 5th, 6th, and 7th prox. The sale will commence at 11:30 precisely each day.

APPOINTMENTS.—The Bolton Corporation have appointed as electricians for the new works in Spa-road, Messrs. E. W. Dickinson, of Wigan, and W. J. Pilling, of Bolton, the commencing salary in each case being £110 per annum. Fifteen applications were received.

AGENCY.—Messrs. W. F. Dennis and Co., of 11, Billiter-street, E.C., have been appointed sole agents for the United Kingdom for telephones and other electrical apparatus manufactured by the Antwerp Telephone and Electrical Works.

LIQUIDATIONS.—Creditors of the Gülcher (New) Electric Light and Power Company (Limited) are reminded that particulars of their claims must be forwarded to Mr. C. Fitch Kemp, liquidator, 73, Lombard-street, E.C., by the 24th prox.

BANKRUPTCIES.—A first and final dividend of 3⅞d. in the £ has been declared in the bankruptcy of Arthur H. W. Radcliffe, electrical engineer, of Clare House, Claremont-road, Handsworth.

——— In the case of Newington, Priddle and Co. (Edward Percival Oliver), of 50, Great Sutton-street, E.C., the liabilities are given at £96. 6s. 10d. and the assets nil. The principal creditor is Mr. W. Mackie (£80).

——— M. L. Ross, electrical engineer, formerly of Queen-street, Cheapside, E.C., was examined at an adjourned first meeting of his creditors, held before Mr. Cooper in the City of London Court last week. The debtor failed about twelve years ago, when carrying on business at Boston, U.S.A. He closed the offices at 90, Queen-street, in 1892, having lost about £6,000 in the business. Since then he has been engaged in the development and sale of various patents, and he attributes his failure to delay in the completion of certain contracts. He denies that he is insolvent, but does not estimate the value of his assets in his statement of affairs ; his debts he returns at £1,954. 10s. The meeting was again adjourned to August 29th, at noon, for a scheme of arrangement to be submitted to the creditors and reported upon by the Official Receiver.

——— A. F. St. George, electrician, of Bermondsey and Earlswood, had a receiving order made against him in June last. It appears that the gross debts are £1,033, of which £529 is unsecured, and that there are no assets. In 1883 he petitioned the court for liquidation, and paid 1s. 6d in the £ on debts to the amount of £3,741. He was adjudicated bankrupt in November, 1886, his debts being £4,504, and no dividend was paid. He has not received his discharge under those proceedings. He attributes his failure to the non-success of his patents (which include patents for manufacturing artificial india-rubber) and to his liability for money borrowed to work them.

——— A summary has been issued of the affairs of George Forrest and Son (Limited), incorporated in 1886, with a nominal capital of £50,000, to acquire the business of engineers and brass founders then carried on by George Forrest and Son at New-street-square and Nevill's-court. The liabilities to creditors amount to £14,207, of which £12,311 is expected to rank, and there appear to be no available assets. As regards contributories, a total deficiency of £39,346 is disclosed. The Official Receiver reports that no dividend has ever been paid by the Company.

ELECTRIC LIGHT FITTINGS.—A new catalogue, containing a number of new and most effective designs of electric light fittings, has just been issued by Messrs. Benham and Froud (Limited), of Chandos-street Works, London, W.C. The contents include full particulars of the revised and reduced prices of these fittings, and in addition give a large number of illustrations of both arc and incandescent varieties. The catalogue is especially strong in pedestal and pendant designs, and includes amongst the former several artistic arrangements for music stands. The prices given show in many cases a large reduction on previous charges, and bring many of the popular designs within the reach of all. There is nothing more noticeable in the progress of electric lighting than the endeavours made by firms like Messrs. Benham and Froud to meet the growing demand for cheap, good and artistic electric light fittings. Copies of the catalogue can be obtained by trade buyers post free on application.

CHLORIDE STORAGE CELLS.—On Saturday last the Goring-on-Thames regatta was held, and the new electric launch "Aphrodite" was used by the Thames Conservancy for clearing the course during the day. The boat was built in Mr. Saunders' boat yard at Goring, and measures 35ft. over all by 5ft. 3in. beam, and, although built for comfort and not for speed, satisfactory results have been obtained in the latter respect. The arrangement of the electrical details have been carried out by Mr. H. A. Earle, of Messrs. Mather and Platt's Westminster branch. The novel feature consists in the employment of a battery of chloride cells for the first time on the Thames, and the launch has been specially built to demonstrate the superiority of these cells for this class of work, their large capacity for a given weight enabling distances and speed to be run without recharging previously impossible. The cells with which the "Aphrodite" is fitted are capable of being discharged at a very high rate, and on the measured mile a speed of nine miles per hour has been obtained, and this rate can, it is stated, be continuously maintained for about three hours. At slower speeds, namely, 6½ miles per hour, which is the usual rate of travel, and which is said to be considerably above the average speed of electric launches of this size, a day's run of nine hours can be undertaken, inclusive of the time taken in passing the locks. The battery power with which the launch is provided is capable of covering a distance of approximately 110 miles without recharging. The chloride cells are manufactured by the Chloride Electrical Storage Syndicate (Limited), 16, Victoria-street, S.W.

THOMSON-HOUSTON PATENTS.—The Laing, Wharton and Down Construction Syndicate (Limited) have purchased the patent rights and privileges of the Thomson-Houston system of lighting, traction, and power transmission in the United Kingdom, and will in future manufacture the plant and apparatus in England. The name of the Syndicate has been altered to the "British Thomson-Houston (Limited)," under which style the business of the Corporation will in future be conducted.

INCOME TAX.—In reference to a note in our last issue, it would appear that there are rival organisations for protecting the public against overcharges for income tax by the Inland Revenue Department. We are desired by the Income Tax Repayment Agency to remind income tax payers that there are two important claims which they should make without delay. The first is for repayment, if the profits of the past year have not reached the amount of the assessment, the second is one in respect of any loss incurred during the year. In both cases a refund of the tax can be obtained, and may possibly bring the balance of income-tax within the limit of exemption or abatement.

ABERDARE.—A public meeting has been held to arrange for the electric lighting of the centre of the town. Mr. J. C. Howell, of Llanelly, explained to the meeting the steps that had been taken to obtain the Provisional Order, and this having been secured, the meeting was asked to make such arrangements as were necessary to secure the carrying out of the Order. An influential Committee was appointed to visit Pontypool, and to report to a subsequent meeting. It is probable that a local Company will be formed to carry out the provisions of the Order.

ARUNDEL CASTLE.—The electric lighting of Arundel Castle was commenced last week. Our readers are referred to *The Electrician* of July 27th, page 371, for a full account of the installation.

BALLINA (IRELAND).—The Board of Guardians have unanimously agreed to consent to the Irish Electrical Supply Company introducing the electric light into Ballina and district on the condition that this permission involve the Board in no expense whatever.

Digitized by Google

BOMBAY.—The Crawford markets and municipal offices are now lighted by electricity, sanction having been given for an expenditure of 700 rupees per mensem up to the end of the current financial year to defray the cost.

BRECHIN.—A special meeting of the Police Commission is to be held to discuss the applications made by the Scottish House-to-House Electricity Company and the Northern Electric Light Company for the sanction of the Commission to their applications for Provisional Orders to supply electric current to the district. Both companies agree to supply electric current at 6d. per unit.

BRIDGEND.—At the last meeting of the Local Board questions were asked as to what was being done with the subject of electric lighting. The Clerk said that the Board were awaiting a report from the Electric Lighting Committee, the Chairman of which said that several members of the Board objected to the expenditure of £200 in the obtaining of a Provisional Order, but he felt sure that had it not been for this expenditure the ratepayers would have been paying 4s. 6d. per 1,000 for gas at the present time. They had, therefore, made up for any expenditure on the electric lighting Order by the reduction in the price of gas, even assuming it were decided to take no further steps.

BRISTOL.—The sanction of the Local Government Board has been obtained for the borrowing of an additional £24,000 for electric lighting purposes, and the money is to be obtained from the Bank of England and to be repaid in 50 half-yearly instalments at 3¼ per cent. interest on the amount remaining unpaid from time to time.

BROMSGROVE.—A public meeting is to be held to discuss the application of Messrs. Hemming and Co., of Birmingham, for permission to erect machinery and plant in this town for the purpose of supplying electric current throughout the district.

BURY ST. EDMUNDS.—The Local Board have been notified by the Board of Trade that the local Electric Lighting Company had applied for the time required for lodging their deposit to be extended. The Local Board decline to take any responsibility in the matter.

CARDIFF.—The National Telephone Company have in contemplation a considerable extension of their telephone system at Cardiff, and a discussion arose at the last meeting of the Public Works Committee of the Corporation as to the arrangements to be entered into with the Company, with special reference to the placing of the telephone wires underground. Some discussion ensued as to the rent to be charged by the Corporation for this privilege. Mr. Gaine (the Manager of the Company) stated that he could not agree to pay anything approaching the sum of £5 per mile as proposed by the Corporation; the Company were willing to pay a nominal rent, but beyond that would not go. The extensions would cost the Company from £4,000 to £5,000 if overhead wires were used, whereas placing the wires underground would cost £20,000. The Company had to pay £75,000 to the Post Office to compete, and for that performed a great public service. After some discussion it was arranged that an agreement should be drawn up by the Chairman of the Committee, associated with Mr. Johnson, the Town Clerk, and the Borough Engineer, and it is understood that the Committee have decided that a rent of. £1 per mile per pipe of 3in. diameter shall be charged.

CARLISLE.—The Town Council having decided not to follow up their application for a Provisional Order, the Brush Provincial Company has given notice of its intention to apply for an order to supply the city with electric current.

CHARGE OF THEFT.—Harry Henderson Owler, electrician, was charged at the Oxford City Police-court with stealing from his employers, Messrs. Baker, Hall and Co., electrical engineers, of Oxford, a quantity of electrical apparatus, &c. The firm were carrying out an electric lighting installation at Wadham College, from which place it was alleged the prisoner had taken the articles which were the subject of the charge. After evidence had been given, the magistrates said that the prosecutors were justified in bringing the charge against the prisoner, who had, in their opinion, brought the trouble entirely upon himself by the course he had pursued. They, however, decided to dismiss the case.

CHESTER.—The Town Council have referred to the Improvement Committee the question of the desirability of acquiring a portion of the site of the old county gaol for the purposes of an electric lighting station.

CRANBROOK (KENT).—The outlying districts of Cranbrook, Sissinghurst, Biddenden, and Frittenden are now being placed in telephonic communication, the work being carried out under the superintendence of Sergeant Campbell, R.E.

DUNDEE.—Messrs. Lowdon Brothers have just completed an installation of the electric light upon the exterior of the extensive premises occupied by Messrs. Clunas and Harrison. Six 2,000-c.p. arcs are used, the current being taken from the Corporation mains.

ELECTRICAL EXHIBITION.—The Ealing Local Board intend holding an exhibition of electrical appliances in Victoria Hall, Ealing, commencing on the 3rd prox., and continuing open till the 13th. This exhibition is held in connection with the forthcoming opening of the Local Board's electric lighting station, and manufacturers and others desirous of exhibiting can obtain information as to space, &c., on application to Mr. C. Jones, C.E., Public-buildings, Ealing, W.

FACTORY LIGHTING.—The new factory just completed for Messrs. Mardon, Son and Hall, at Temple Gate, Bristol, is being fitted throughout for the electric light by Messrs. F. W. Ball and Co. 500 16-c.p. incandescents will be used, and arrangements made to allow for an additional 120 lights later on. The plant includes an Edison-Hopkinson 350-ampere machine. The consulting engineer for the work is Mr. E. J. Tongue. This installation, when completed, will be the largest in Bristol.——The contract for lighting the new stay factory of Messrs. C. Bayer and Co., at the Oldlands Common, near Britton, has been secured by Messrs. A. McTavish and Co., of Bath. 120 16-c.p. incandescents will be used, and the contract includes the supply of the necessary plant.

FAREHAM.—The Local Board have adopted an amendment modifying the resolution passed in June last for the purchase of the Fareham Electric Light Company's undertaking for a sum not exceeding £5,000. By the amendment a valuation is to be made of the Company's property and undertaking before purchase.

GRANGE (LANCS.).—The Local Board have discussed a report on the electric lighting question presented by the Town Clerk, and have decided that inquiries should be made as to the probable cost of lighting the district before deciding on the advisability of applying for a Provisional Order. The application made by the Windermere Company for the Board's consent to their application for a Provisional Order has been referred to the Electric Lighting Committee for consideration.

HALIFAX.—The recent strike of joiners is estimated to have delayed the work in connection with the Corporation's electric lighting station for about a week; but, notwithstanding this delay, progress has been sufficiently satisfactory to warrant the opinion that the works will be ready for opening early in November. Already orders have been received for about 2,000 out of the 5,000 lights for which plant is being put down, the customers including banks, the principal business houses, and several places of worship.——By a small majority it has been decided not to light the Town Hall by electricity. The proposal involved an expenditure of £500, and, after considerable discussion at the last meeting of the Finance Committee of the Town Council, a negative motion was approved.

HAMPSTEAD.—Power has been granted to the Electric Lighting Committee to engage such staff as may be necessary for working and tending the plant of the central electric supply station. Mr. R. A. Chattock, the recently-appointed chief electrical engineer to the Vestry, commences his duties on September 3rd, and the machinery and mains are to be thoroughly tested before October 1st, the date fixed for turning on the light.

HEREFORD.—The Lighting Committee of the Town Council have reported that they have had encouraging replies to their circular asking for support for the electric lighting scheme, and Mr. Alderman Shelley, in moving the adoption of the Committee's report, said that they had trebled the number of applications on this occasion to those previously received when a similar circular was issued. There was no doubt that the electric light would receive the support of the principal tradesmen and householders in the district.

HOTEL LIGHTING.—Messrs. Rashleigh Phipps and Co. are fitting out Limmer's Hotel, Conduit-street and George-street, W., for the electric light, and have also received a contract for the lighting of the Howard Hotel, Norfolk-street, W.C., the latter installation requiring 450 16-c.p. incandescents.

HUDDERSFIELD.—The Electric Lighting Committee of the City Council have decided to lay an additional main along Victoria-street, and have adopted a system differing somewhat from that originally selected. A sub-committee has been appointed to consider the desirability of reducing the price per unit, and of adopting a graduated scale. They will also consider the question of reducing the meter rents.

ISLINGTON (LONDON, N.).—The Vestry have received from the Board of Trade a communication giving a provisional approval to the system of electric lighting adopted by the Vestry.

LANCASTER.—The trustees of the Palatine Hall have decided to light the building by electricity. Mr. Barnard, the borough electrical engineer, has prepared the necessary specification, which has been adopted by the trustees.

LEICESTER.—The sum of £250 is to be expended in the wiring and fittings for lighting the principal apartments at the Assembly Rooms, the current being taken from the Corporation mains.

MIDDLESBROUGH. In criticising the result of the past year's working of the local gas works, the *Daily Gazette* points out that the good dividends earned are largely owing to the fact that coal is

Digitized by Google

very cheap in the district, and that the introduction of the electric light is, therefore to some extent retarded. The journal points out that in the northern districts water power of considerable magnitude is now running to waste, and might be profitably utilised for electric lighting purposes. The initial outlay would be heavy, but the ultimate result would be a great saving in the cost of lighting, both public and private.

Mill Driving.—The London *Daily News* states that the city of Bremen is shortly to be in possession of an ever-revolving "windmill," and that the firm of Schuckert and Co. have been commissioned to build and erect an electric motor in the extensive mill owned by Herr Oscar Wolff, Ausgaruthor, the motor to be so arranged that the mill can be controlled at will, the current to be supplied from the city mains.

Mill Lighting.—Messrs. J. H. Holmes and Co. have secured the contract for lighting the extensive mills of Messrs. Joshua Smith (Limited), at Cornholme, the alterations and extensions to which have cost between £20,000 and £30,000.

Monmouth.—The Town Council are to discuss, at a special meeting this week, the report from Messrs. Bramwell and Harris on the drainage and the electric lighting scheme.

Montrose.—A private meeting of the Electric Light Committee of the Police Commission was held last week to again consider the question of lighting the district by electricity. A lengthy discussion took place, but no definite resolution was come to, the principal point being whether the Scottish House-to-House Company should be allowed to obtain a Provisional Order to proceed with the lighting of the town, or whether the Commissioners should themselves apply for an Order. A special meeting of the Council is to be held on the 10th prox. to finally decide this question. The subject has been before the Commissioners for three years.

Newcastle-on-Tyne.—Messrs. J. H. Holmes and Co. have secured the contract for fitting up the extensive premises of Messrs. Galloway and Co., wholesale confectioners, in Clayton-street, with the electric light.

North Riding (Yorks.).—The Electric Lighting Sub-Committee of the County Council have discussed a proposal from the Caledonian Electric Supply Company for taking over the Provisional Order obtained by the Corporation. It was finally decided that the Borough Surveyor obtain information from towns which have adopted the electric light, and submit the same at the next meeting of the Committee.

Perth.—The Town Council have refused to consent to applications made by the Municipal Electric Light and Power Corporation (Limited) and the Caledonian Electric Supply Company (Limited), under the Electric Lighting Acts.

Pontypool.—It has been decided to light the recently completed market by electricity.

Radcliffe.—The Electric Lighting Committee of the Local Board have resolved to request Mr. Bennett to state upon what terms he is prepared to provide the plans and estimates for an electric lighting station plant and all necessary appliances and accessories, and to give all engineering assistance required, up to and including the obtaining of a Provisional Order to light the district by electricity, and also the terms upon which he is prepared to carry out the works from the obtaining of the Order to the completion.

Stirling.—The Police Commission met to-day (Friday) to make the necessary arrangements for applying for a Provisional Order for lighting the district by electricity. Notice has been given by the Caledonian Company and the Scottish House-to-House Company of their intention to apply for Provisional Orders to light the burgh.

Stowmarket.—An important meeting was held last Wednesday in the Institute Hall to consider the desirability of adopting the electric light at Stowmarket. The meeting was attended by the principal tradesmen of the town and many of the chief private residents. Mr. Napier Prentice gave the meeting some statistics on the subject. Subsequently Mr. Prentice and Mr. C. R. Dewhirst were appointed as a Committee to approach the local gas company with a view of inducing them to supply the town with electricity. In connection with the meeting there was an exhibition of domestic electrical appliances for cooking and heating.

Taunton.—At the meeting of the Town Council, on Tuesday, the electrical engineer, Mr. H. W. Couzens, stated that during the past quarter the improvements and alterations at the electric lighting station, which has been suggested by Dr. Fleming, had been completed and examined and approved by him. The Electric Lighting Committee have insured the electric lighting station machinery and plant for £6,000, at 4s. per cent.

United States Tariff Bill.—The Bill has now finally passed, and iron, coal, and other items of large consumption have been placed upon the free list. The reductions under the new law do not materially affect the electrical industries.

Walthamstow.—The Local Board, having arranged to build a new Fire Brigade station, have decided to fit out the principal thoroughfares in the town with street calls, &c. The work has been entrusted to the Private Wire and Telephone Installation Company, whose standard fire alarms are to be fitted up, and communication is to be established between the new fire station and the firemen's dwellings.

Waverley (New South Wales).—The Town Council a short time back passed a resolution that the police had been provided with portable electric lanterns similar to those in use in New York. It is stated that the suburban police in the district are unprovided with lanterns of any kind.

Wednesbury.—The Gas and Water Committee of the Town Council have had under consideration the electric lighting question, and Mr. Griffiths, in presenting the report of the Committee, said it had come to the conclusion that an electric lighting scheme was "too big an order" to be entertained at present.

Windermere.—The Windermere Electric Light Supply Company have written the Local Board a lengthy document setting out the conditions under which they propose to light the district by electricity. The Company point out that they have an authorised capital of £50,000, and that they are supported by the Brush Electrical Engineering Company of London. It is proposed to use water power, and the Company have obtained this from the rivers Leven and Troutbeck. The new Company has been amalgamated with Messrs. R. H. Fell and Son, and an assurance is given to the Local Board that overhead wire will be entirely dispensed with, and nothing done to detract from the beautiful scenery of the lake district. The Company undertake to supply the whole of the Windermere district with electric current. The Company's scheme is an extensive one, and it is pointed out that it is only by such an arrangement that an area so thinly populated can be worked economically. The Company propose to supply accumulators for the launches on the lake, and to make a feature of supplying current for domestic purposes. The Company's application is to be further discussed at the next meeting of the Board.

York.—The extensive premises of Messrs. Cotts and Falconer, of this city, are being installed throughout with the electric light by Mr. Edward B. Pym, of Scarborough. The plant includes a 9-kilowatt machine and Otto gas engine.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. Chapman, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

August 4, 1894.

14,987. W. L. Wise. London. Improvements in or relating to the separation of caustic alkalies from the liquors obtained by the electrolysis of alkaline salts (Solvay and Co., Belgium).

14,988. W. L. Wise. London. An electrolytic table (E. Solvay, Belgium).

15,000. H. Soifrank. London. An improved wind motor for driving electric machinery, and other purposes.

15,004. G. Ritter. London. Improvements in telephonic installation.

August 7, 1894.

15,034. W. Thomson (Baron Kelvin). Glasgow. Improvements in instruments for measuring electric currents.

15,051. R. Middlemass. Scarborough. An improved grip to be employed in laying electric cables.

15,065. E. Tyer. London. Apparatus for making electrical contact by passage of a railway train.

15,070. W. J. Brewer. London. Improvements in overhead conductors for electric railways and tramways.

15,082. E. Tilmann and C. K. Lenow. London. Improvements in magneto-electric machines for cycles or other vehicles and driving gear for the same.*

August 8, 1894.

15,129. A. Malignani. Manchester. An improved process for evacuating incandescent lamp bulbs.

15,170. J. J. Rathbone and A. Chester. London. Improvements connected with arc lamps.

August 9, 1894.

15,219. E. Müller. Liverpool. Improvements in the method of and means for preventing undue reciprocal influences between telephonic lines, or between telephonic and telegraphic or other electrical lines.*

SPECIFICATIONS PUBLISHED.

Note.—All Specifications can now be obtained at the uniform price of 8d. each.

1893.

14,130. Hargreaves and Bird. Electrolysis of iodides, bromides, &c.

14,131. Hargreaves and Bird. Electrolysis of chlorides, iodides, &c.

15,485. Mann and Hopwood. Glow lamps and holders.

11,861. Lake (Miles). Electric belts.

COMPANIES' MEETINGS AND REPORTS.

Crompton and Co. (Limited).

The sixth annual general meeting of this Company was held on Monday at Cannon-street Hotel, Viscount Emlyn (Chairman) presiding.

The SECRETARY (Mr. Francis R. Reeves) read the notice calling the meeting.

The CHAIRMAN: Gentlemen, as you will have noticed, the statement of accounts show a slight reduction of gross profits as compared with the statement laid before the shareholders at the meeting in July last year. But there are, notwithstanding this, several matters on which, I think, we may fairly congratulate the shareholders. First of all, the amount of business done exceeds the turnover of the previous year by just £22,000. And, secondly, by careful economy, and watchfulness over items of expense, we have been able to reduce the item in the Profit and Loss Account, which is headed, "Trading and Office Expenses, Salaries, &c," by a sum of £3,000. The accounts before the meeting, I should say, show a diminution of £4,000; but the difference is occasioned by the fact that the Directors, this year, have taken the interest on bankers' loans from the Profit and Loss Account, and placed it in the Revenue Account, which is, in our opinion, the more correct way of dividing the expenses. Although the accounts then show a difference of £4,000 the net result is practically a saving of £3,000 in the expenses of the year. The Directors have under consideration further economies, which they are proposing to effect and have begun to effect, by re-arranging some of the departments of the Company. It is hoped that by these economies we shall show a still further satisfactory reduction in the expenses, next year, under this head. It will be observed that the item of "Depreciation of Plant and Machinery," has increased by £900. This is partly accounted for by the previous year's increase in the respective items dealt with in the Depreciation Account, but it is also due to the desire of the Directors to err rather on the side of over-caution in dealing with the Company's accounts, than to submit a statement to the shareholders of too favourable a character. You will see, by continuing the examination of the figures in the published statement of accounts, that there is an apparent further increase in the item of Subsidiary and other Companies. This increase is due, mainly, to the fact that an additional item in respect of the Chelmsford Electric Lighting Co., has been transferred from trade debtors to Investment Account, and also to the fact that the Company has had to take a considerable amount in debentures of the Australian Company, instead of cash, in part payment of the debt owing by that company to us. This need not be regarded as an investment absolutely. Practically it is, but it is only the result of an arrangement which has been made to take over these debentures until the Australian Company is in a position to pay us cash. It is not, in any way, a permanent investment, although it appears, for the present, as an addition to the amount we hold in subsidiary and other Companies. Both these items have been transferred from the trade debtors to investments; but, notwithstanding these transfers, the item of trade debtors shows a slight increase over the amount of the previous year. The stock-in-trade shows an apparent decrease on last year; but this is in consequence of separating the item "work in progress" on contracts, from "stock in trade." Practically there is hardly any alteration in the amount of stock carried. We have only divided them, as we thought by doing so we should make them clearer. There is another matter which you will expect me to say something upon, and that is with respect to the depreciation and the proposed writing off of assets. In reply to some questions addressed to me at our meeting in January last, I explained that no contracts whatever had been accepted by the Directors for several years—between three and four years—under which the Company was bound to take payments in shares and securities, instead of receiving cash for work done. During the past year, unfortunately, some of the securities taken in former years as part payment have, in our opinion, depreciated, and on looking carefully into them we felt they should not stand in our books at the amount credited to them. The Directors, therefore, applied to Mr. Crompton and Mr. Albright, the Managing Directors, and placed before them the desirability of reducing the amount at which the securities stood. They met us in the fairest manner, and undertook to surrender whatever Ordinary shares were necessary to clear any doubtful securities from the Company's books. Taking advantage of this offer, we have carefully examined the whole of our assets, and have endeavoured to wipe off our books any that appeared at all doubtful, and if we have erred I feel sure it has been on the side of writing down the account very severely, for the amount we propose to write them down by is no less than £20,000. I should explain, —although perhaps it is not necessary to the meeting, but for the benefit of those outside—that this is merely, so far as the assets are concerned, a bookkeeping transaction. The assets are still available for what they are worth as previously; and if they should eventually improve in value, the improvement, whatever it is, will be to the advantage of the shareholders generally. At the conclusion of our business it is proposed that we should make the meeting special for the purpose of passing a special resolution which will enable us to carry out this agreement. It will be necessary to hold a further meeting to confirm the resolution, and then an application will be made to the Court of Chancery to sanction the cancelling of the capital in question. Not only the shareholders, but the Directors also, owe a debt of gratitude to the Managing Directors, for the way in which they have assisted the Company in dealing with this matter in the manner I have described. Since our last meeting the Manager of the Company's works at Chelmsford has resigned, owing to his having accepted another engagement. The Directors have placed Mr. Brunton in the position of Manager, and they have every confidence that under him the works will be carried on well. The result of the past few months have fully justified the view we took of Mr. Brunton's ability. I hope Mr. Crompton will say a word about this matter, as he is specially interested in the works at Chelmsford. Last year mention was made of the prospects of the Australian Company, and I then said that there were signs that the business in Australia was likely to improve. I am glad to be able to tell you that the result has justified that statement. The orders from the Australian Company at present on the books amount to a very considerable sum; and we learn from the latest mail from Sydney—last week's mail—that the contracts in hand, which were practically secured at that date, amounted to about £40,000. That will give you some idea of the development of the Australian Company. Now, in a great deal of the work we do we have to compete closely with many other companies; but there are one or two departments in which we have specialities, and these, we hope, will bring us a large amount of business. I think I referred the last time I addressed you to the arc lamp department. I am glad to say that is going on well, and I hope we have in that a valuable property. The other department comprises the cooking and other domestic appliances. That, too, is going on very well, and bids fair to prove of considerable value. We hope it may develop with some rapidity. The City of London Electric Lighting Company have opened a show-room in Queen-street, Cheapside, where they are exhibiting some of our cooking stoves and other appliances. As these inventions become better known, and the cost of manufacturing them is reduced, owing to increased demand, we shall be able to sell them at a cheaper price, and we then anticipate that a large business will be done in this department. The Vestry of St. Pancras have issued a number of circulars recommending the electric stoves and cooking appliances of our Company. That is a good example, and we hope it will be followed by others. At any rate it is a testimony to their value, and shows how much these things are appreciated by those who understand them. Well, gentlemen, of course I should have liked to have told you that we were going to pay the full Preference dividend. The net profits would have allowed of the payment of a larger dividend than we recommend, and we could have had recourse to the reserve fund, and in addition to that there is the balance we propose to carry forward, which could have been applied to the payment of a dividend. After careful inquiry, however, we thought that the best interests of the shareholders would be consulted by paying a moderate dividend now. We deem it advisable to increase the amount set aside for contingencies to £1,000, and the balance of net profits to be carried forward to next year's account, after paying the dividend, will be slightly over £1,000. And this, I may point out, will be available for dividend next year. At our meeting in January last it was explained to the shareholders why the Directors had not declared an interim dividends, the reason being that although the Company had earned a moderate profit the indebtedness to the Company's bankers had become such a large item that it was felt inadvisable to declare a dividend at that time, or until the proposed new issue of debentures, with respect to which we held that meeting had been placed. The Directors are still in the face of the same difficulty, inasmuch as the response of the shareholders and debenture-holders to the Directors' invitation to take up the new debentures has only been met to the extent of £32,000. The Directors feel that they cannot urge too strongly upon the shareholders the necessity which exists for subscribing to the new debenture issue, so as to place the Company on a firm footing. It is not, as I explained before, a satisfactory position for a Company to be in to owe such a large amount to its bankers as we owe now, and, besides, the want of ready money cripples us in dealing with such matters as we have to deal with in a business of this kind. It prevents us from buying in the cheapest market, and hampers us in many other ways. We hope the shareholders will appreciate the manner in which we have dealt with the affairs of the Company, as shown by the balance-sheet, and that they will show that appreciation by accepting our assurance that we believe the Company to be thoroughly sound, and assisting us to put it on a firm footing by endeavouring to take up the debentures we have offered. I shall be glad to answer any questions shareholders may wish to ask, and in the meantime to place myself in order, I beg to move:—

"*That the report of the Directors and audited statement of accounts to March 31, 1894, be, and the same are hereby received and adopted.*"

Mr. R. E. B. CROMPTON (one of the Managing Directors) in seconding the motion said: I continue to feel myself very largely responsible to you for the conduct of the Company's business, and therefore I presume you will wish to hear something from me personally. I can only corroborate everything your Chairman has said with regard to the past year's working and the future of the Company. Without doubt the past year has been adversely affected by the competition of new firms that have

Digitized by Google

entered the field to manufacture electric appliances without a full knowledge of what they were doing, and this has had the effect of reducing market prices to such an extent that it has been a very hard matter indeed to fill our order sheet with profitable orders. We believe, however, that there are signs that this period of extremely low prices, based on erroneous estimates, is coming to an end. It must necessarily work out its own cure. The weaker firms will be gradually weeded out as they find such contracts as they have made cannot be carried out in a paying fashion, so that we may look forward, as one of those firms who will continue, to having better prices and better times in the future. As regards the change in the management at Chelmsford I can only confirm what the Chairman has said. Mr. Brunton, your present Manager, is the best man I could possibly have selected. In our opinion the Company is now in a better position than ever it was before to meet the severe competition of the present day by manufacturing goods as cheaply and economically as possible. I do not believe that at any time our manufacturing department was in better order. With regard to prices, I hope, as I have just said, the tendency will be rather to increase than to diminish; but if the low prices of the past year continue during the present year, I feel convinced that we are at least in as good, and probably in a better, position for meeting such a state of affairs by manufacturing at an extremely low rate than any other firm I know of in England. Consequently we may be able to take contracts which will yield us a profit, whereas they would not be profitable to our competitors.

The motion was then carried unanimously without discussion.

The CHAIRMAN then proposed—

"*That a dividend at the rate of 3s. per share be declared and paid on the Preference shares of the Company.*"

Mr. J. ALBRIGHT (joint Managing Director with Mr. Crompton) seconded the resolution, which was passed.

Mr. CROMPTON moved the re-election of the Chairman as a Director. Mr. TUFNELL, Sen., seconded, and it was unanimously agreed to.

On the motion of Mr. TUFNELL, Sen., seconded by Col. JAMESON, the auditors (Messrs. J. H. Duncan and Co.) were reappointed.

At an extraordinary general meeting, which was held at the conclusion of the annual meeting,

The CHAIRMAN said: I beg to move—

"*That the capital of the Company be reduced from £300,000 to £280,000 by cancelling paid-up capital which has been lost, or is unrepresented by available assets, to the extent of £20,000; by cancelling 4,000 Ordinary fully paid-up shares of the Company, numbered 2,785 to 6,784 inclusive, which have been issued.*"

I have already explained the reasons for this resolution. The Board believe that it embodies the best course we can pursue in dealing with the depreciation on certain securities, as we do not think we should keep any on the books which are of doubtful value.

Mr. OSBORNE seconded the resolution, which was unanimously carried.

On the motion of Col. JAMESON, seconded by Mr. TUFNELL, sen., a vote of thanks was accorded to the Chairman, after which the proceedings terminated.

Liverpool Overhead Railway Company.

The twelfth ordinary half-yearly meeting of the proprietors of this Company was held on Tuesday, in the Law Association Room, Cook Street, Liverpool, Sir Wm. B. Forwood presiding.

The CHAIRMAN, in moving the adoption of the report (which appeared in our issue of the 3rd inst.) and statement of accounts, said he was glad to think that the report which the shareholders had before them was of a very satisfactory and encouraging character. During the past half-year the traffic on their line had increased to an extent which ought to give them all great encouragement for the future. As in all new undertakings, it was difficult to get figures for the purposes of comparison. For instance, if they compared the traffic of the past half year up to the end of June with that of the preceding half-year, they would be comparing the traffic of a summer half-year with the traffic of a winter period, and if they took the winter half-year they would be comparing it with a broken half-year, for the line was opened in the month of April last year. During the half-year ended June 30th they carried 2,851,437 passengers, as against 2,475,639 in the half-year ending December 1893, or an increase of 391,0CC. It was impossible to compare these figures with those of the previous half-year, as the latter was a broken period; but he had some figures which would give an indication of the increase of traffic at the present time. During the last half-year they carried 15,300 passengers per day, and during the corresponding period they carried 11,810 per day; and taking the traffic from April 30th to June 30th last year and comparing it with the same period this year, they found the receipts for the former period, nine weeks, to be £5,890 as compared with £8,045 for the corresponding nine weeks this year, showing an increase of £2,155. That was a very gratifying increase, and since the close of the half-year with which they were dealing the increase in traffic had been kept up. During the six weeks that had elapsed since June 30th they had received £1,100, which he considered as very satisfactory. They opened the Seaforth Sands station on April 30th, and their traffic from that station had been everything they expected it to be. It was a valuable feeder to the line. During the half-year they had opened two new stations—one at Nelson Dock and the other at Huskisson, the latter being a removal from the Sandon Graving Dock, and on Wednesday they proposed to open another new station at the Langton Dock, which experience had shown to be necessary. With these three stations the line would be complete, and he might say that it would be an omnibus line, and that passengers would have no complaint to make on the ground of distance between the stations. He would also direct the attention of the shareholders to the fact that the Company had made an arrangement with the Tramway Company, by which they had secured the co-operation of that powerful Company. It was an arrangement which would be advantageous to both, and to which he looked forward in the hope of a considerable increase in traffic. Turning to the revenue account, he found that they had received for the half-year £20,044. 7s. 6d., showing an increase of £1,696 on the previous half-year. That figure might be disappointing to them, seeing the increase in the number of passengers, but as that increase was due to the cheap workmen's tickets in the early morning they would understand why the increase in the revenue did not average much more than one penny per extra passenger carried. The Directors were pleased with the development of the early workmen's trains, and thought they were getting very well compensated for the work done. Coming to the expenditure, they had spent £14,947, being an increase on the corresponding half-year of last year of £1,215. That was made up of two or three items, including £425 on the ventilation of carriages and other alterations; and an additional sum of £873 on traffic expenses, which was largely made up of the cost of the new stations and the cost of running the 22,000 extra miles. They had also had an increase in the rates of £255, and the law charges were somewhat heavier than the previous half-year. On the other hand, they had effected a saving of £910 by taking over the generating station into their own hands. The total receipts were then £20,000, and the working expenses £14,947, leaving £5,097 to be dealt with. They had paid interest of debentures and calls in advance £2,639, leaving £2,457, which by the addition of the balance from last year of £2,598, gave £5,066 available for dividend. The Directors recommend the payment of 5 per cent. dividend on the Preference, and 1 per cent. on the Ordinary shares, leaving £1,010 to be carried forward. As regards the future, they were fully alive to the importance of the extension of the system, and but they wished to see the present undertaking a little further developed, and they would not do anything without obtaining the sanction of the shareholders. They believed that there was a large field for traffic awaiting them at the south end. Their claim against the Dock Board had not yet been adjusted, but they hoped soon to effect an amicable arrangement. He paid a tribute to the work and ability of the engineer, Mr. S. B. Cottrell, and referred to the interest taken in their work by the servants generally, among whom existed a splendid *esprit de corps*, and for whose benefit the Company had recently opened an institute at Seaforth Sands station.

Mr. RICHARD HOBSON seconded the motion, which was agreed to.

A vote of thanks to the Chairman and Directors closed the proceedings.

Birmingham Central Tramways Company.

The thirteenth annual meeting of this Company was held on Wednesday at the Queen's Hotel, Birmingham, Mr. J. Ebbsmith presiding.

The CHAIRMAN, in moving the adoption of the report (which appeared in our last issue), referred to the recent decision of the House of Lords upon what was known as the purchasing clause of the Tramway Act, a decision which was adverse to the contention of the tramway companies affected and favourable to the local authorities. There was a great deal of misapprehension with regard to the effect of that purchasing clause, and therefore it would be satisfactory to many shareholders when he stated that that decision had no injurious effect upon the position of the Company. In Birmingham the Central Company's lines were divided into two classes—first, those which were held directly from the Corporation within the city, upon a lease which expired at the termination of twenty-one years, so that they were not affected at all by the decision; and, secondly, by the lines outside the city, in respect to which they were subject to the statutory conditions. In 1888 the constructive value of their lines was taken, and it was that value which appeared in their books now. Dealing with the accounts, the chairman said the new engines referred to at the last meeting had been received and were working admirably. It was satisfactory to find that upon those engines a saving of close upon three farthings per mile was effected in the consumption of fuel alone, and he was hopeful that the saving would be more marked during next year. The horse department was what it had always been—a difficulty, and a blot upon their accounts. In the cable department there had been a most satisfactory increase of working profit. They could not have their profit at both ends, and he was glad to know that the profit on the cable department far outweighed any corresponding loss upon the horse department on the southern routes. The electric department was one of mingled difficulty and hope. The shareholders were aware that the Corporation had not met the Directors as they had a right to expect in the hope of establishing another and more economical form of traction; but the Directors had turned their attention to two alterations of detail in the present system, which gave them distinct reason to believe that the electric department had seen its worst days, and that it would now show a steady if unsatisfactory improvement. He said "unsatisfactory," because he considered it was unsatisfactory that they should be compelled to work that form of traction which could be replaced by one of equal advantage to the public and much more economical to the Company. He was quite sure if the Corporation had permitted the experiment of overhead lines to be tried in the Bristol-road, the inhabitants of that thoroughfare would in three months have warmly supported a continuance of the system, and the profit to the Company would practically have equalled the loss which they now sustained. The £550 paid to the late Managing Director (Mr. Carruthers Wain) was a proportionate payment made upon the determination of his agreement, which expired at the end of last year. He had done his work of organisation, and done it well. His retirement necessitated a reorganisation of the management, and as their traffic manager (Mr. Herring) about that time left the district they requested Mr. Holmden, in whose ability, probity, and assiduity they had profound confidence, to act as manager as well as secretary. The effect of the reorganisation of duties had been to diminish the standing

Digitized by Google

charges by £1,100 per annum. The shareholders would be called together at a special meeting to consider the question of a proposed reduction of capital.

The report having been adopted, Mr. J. Booth and Mr. J. Ebbsmith were re-elected Directors, and Mr. J. T. Mantle was appointed a Director in place of Mr. Martyn J. Smith, who retired.

Cuba Submarine Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended 30th June, to be presented at the forty-sixth ordinary general meeting to be held at the offices, 58, Old Broad-street, London, E.C., on Wednesday next, the 22nd inst., at noon :—

The gross receipts amount to £24,703. 9s. 0d., and the gross expenditure to £5,133. 8s. 1d., leaving a sum of £19,570. 0s. 11d., which, added to the balance brought from the last account, £2,259. 5s. 0d., leaves £21,829. 5s. 11d. at the credit of revenue account. Of this, the sum of £1,000 has been set aside as a further reserve against any loss from the deposits with banks. In view of the reserve fund having shortly to bear the cost of the new cable referred to below, the sum of £8,000 has been added to it, making the fund £113,000. The dividend on the Preference shares will absorb £3,000, and leave £9,829. 5s. 11d., out of which the Directors recommend the payment of a dividend on the Ordinary shares at the rate of 8 per cent. per annum, free of income tax, the balance £3,429. 5s. 11d., being carried forward to the current half-year.

The cables have continued in good order throughout the half-year. A contract has been entered into with Hooper's Telegraph and India Rubbber Works (Limited), for the manufacture and laying of a new cable between Batabano and Cienfuegos, to replace the original 1870 one, which, as mentioned in last report, gave out at the end of the year. This cable will be laid in the beginning of next year and its cost charged to the reserve fund.

The Company's suit against the Spanish Government at Madrid has made progress, but no decision has been given.

The Director who retires from the Board at this time is Mr. Alexander F. Low, who, being eligible, offers himself for re-election, as does also Mr. John Gane, the Auditor.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.*]

EDMONDSON ELECTRICITY METER SYNDICATE (LIMITED).—This Company was registered on August 10th, with a capital of £2,000, in £1 shares, to acquire the patents and patent rights for the manufacture of electricity meters, invented and patented by Joseph Edmondson, of Bradford, Yorks., electrician, either alone or in conjunction with Joseph Oulton, of Bradford, clock maker, to manufacture and deal in electricity meters, and all apparatus, appliances, materials, and things connected with the measuring of electricity, or with the generation, accumulation, supply, distribution or employment of electricity, and generally to carry on the business of electricians and mechanical engineers. The subscribers include Joseph Edmondson, Heath-avenue, Halifax, electrician ; Frederick Priestman, J.P., Pierremont, Bradford ; Edward Priestman, Moorfield, Bradford ; and Joseph Cooper, Ilkley, Yorks.

BRITISH THOMSON-HOUSTON, LIMITED (formerly the Laing, Wharton and Down Construction Syndicate, Limited).—An agreement, dated June 27, 1894, with the Thomson-Houston International Electric Company, of New York, provides for the allotment, as fully paid to that Company, of 3,010 shares (Nos. 4,727 to 7,736 both inclusive). By a special resolution, passed July 11 and confirmed on July 26th, the name of the Syndicate was changed to the British Thomson-Houston (Limited), and the permission of the Board of Trade for such change of name was granted on August 2nd. The annual return, made up to July 25th, was recently filed. Out of a nominal capital of £100,000, in £10 shares, 7,526 have been taken up, and of these 4,140 have been issued as fully paid. The full amount has been called on 2,660 shares, £5 per share on 329 shares, and a call of £2. 10s. per share has been made on 397, resulting in the receipt of £29,237. 10s.

HEAD, WRIGHTSON AND CO. (LIMITED).—The annual return of this Company, made up to July 7th, has been filed. The whole nominal capital of £210,000, in £5 shares, was taken up, and the full amount called and paid. The total amount of shares for which share warrants are outstanding, comprising 98 of 20 shares each, 140 of 10 shares each, 200 of 5 shares each, and 489 of 1 share each, is £24,245, while share warrants, comprising 5 shares have been surrendered since last summary.

HOOPER'S TELEGRAPH AND INDIA RUBBER WORKS (LIMITED).—The statutory return of this Company, made up to August 7th, has been filed. The capital is £50,000, divided into 2,500 Preference and 2,500 Ordinary shares of £10 each. 2,000 have been taken up, and the full amount called on 1,496 shares, while a call of 2s. per share has been made on the remaining 504 shares, resulting in the total payment of £15,010. 8s.

LONDON AND HAMPSTEAD BATTERY COMPANY (LIMITED).—The annual return of this Company, made up to June 19th, has been filed. Out of a nominal capital of £50,000, divided into 7,000 Preference and 3,000 Deferred shares of £5 each, 830 Preference and all the Deferred have been taken up, and the latter were all issued as fully paid. Upon the 830 Preference shares the full amount has been called, resulting in the total payment of £4,150.

CITY NOTES.

CHARING-CROSS AND STRAND ELECTRICITY SUPPLY CORPORATION (LIMITED).—The Directors have declared an interim dividend for the half-year ended June 30th, at the rate of £4 per cent. per annum on the Ordinary share capital of the Corporation (£150,000), and carried forward £1,335, after payment of £5 per cent. per annum on debentures.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended August 12th were £897, as against £829 in the corresponding period of 1893, being an increase of £68. The total receipts for the half-year amount to £5,203, as against £5,066 for the corresponding period of 1893, an increase of £137.

DENIAL.—We are informed that there is no truth in the announcement that subscriptions are being privately invited for the shares of the Brockie-Pell Electric Lighting Company (Limited), which was stated by a financial contemporary to have been registered with a capital of £80,000. Consequently the statement that the Company is to pay to the vendor £55,000 for the patents, and a royalty of 5s. per lamp, is also at variance with the facts.

GREAT NORTHERN TELEGRAPH COMPANY.—The coupons falling due on September 1st next on the Debentures of 1883, Series B, should be presented for payment between the hours of 11 and 2, at the office of Messrs. C. J. Hambro and Son, 70, Old Broad street, where lists may be obtained. Coupons must be left three clear days for examinations.

GULCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY (LIMITED) (*in liquidation*).—At the meeting called yesterday (Thursday) to confirm a resolution passed on the 1st instant, that Mr. C. F. Kemp (the liquidator) be authorised to enter into an agreement with Messrs. Easton, Anderson and Goolden (Limited) on terms set out in our issue of the 27th ult., page 379, was confirmed, and Mr. Kemp now proposes to pay in cash the first mortgage debenture-holders, and hopes to be in a position eventually to pay all unsecured creditors.

W. T. HENLEY'S TELEGRAPH WORKS COMPANY (LIMITED).—This Company have, during the current week, invited applications for £50,000 Four and a-Half per Cent. Mortgage Debenture Stock at par in multiples of £10. The authorised capital of the Company is £100,000, and the subscribed capital £98,370, £30,000 Preference and £68,370 Ordinary. The prospectus states that the increase in the Company's ordinary business (as distinct from laying submarine cables), and the prospect of extending the business in new directions, render it advisable to increase the capital of the Company, hence the issue of this Four and a-Half per Cent. Debenture Stock. This issue is to be secured by a trust deed, and to be a first charge upon the Company's property and undertaking. For this purpose a sinking fund is to be created, to commence with the year 1900, for which will be set aside out of the profits a sum of £1,000 annually for the purpose of redeeming the stock. £20 is to be paid on application, £20 on allotment, and the balance by December, 1894 The prospectus contains a waiver clause as to contracts and agreements, and must be referred to for other particulars.

SOUTH METROPOLITAN GAS COMPANY.—Mr. George Livesey, at the meeting of this Company on Wednesday last, referred to the very considerable income derived from the penny-in-the-slot gas meters of which the Company has now 20,000 in use. He referred to the profit-sharing system adopted by the Company, under which the officers and working staff have benefited to a very material extent. As to the purchase of the Metropolitan Gas undertakings by the London County Council, Mr. Livesey is of opinion that such a scheme would result in a much more expensive system of working, and would not result in any benefit to gas consumers. A dividend at the rate of 13 per cent. per annum was declared.

A. AND J. STEWART AND CLYDESDALE (LIMITED).—A half-yearly interim dividend at the rate of 2½ per cent. per annum has been declared, payable August 31st.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to appoint a settling day in and to grant a quotation to £150,000 Four and a-Half per Cent. First Mortgage Debenture Stock of the Metropolitan Electric Supply Company (Limited).

TRAMWAY COMPANIES' DIVIDENDS.—The *Financial News* of the 14th inst. contains an interesting article on the subject of tramway company dividends as affected by the recent decision of the House of Lords, with special reference to the reserve funds of these undertakings. In regard to this subject Mr. W. S. Graff-Baker points out that in cases similar to that of the Dublin United Tramways Company, it is unnecessary that a reserve fund of any magnitude should be created, as the Company have built their line under an Act from the Privy Council of Ireland granting the use and enjoyment of the lines to the tramway company in perpetuity, under which arrangement no question of the purchase of the undertaking by the local authority can be considered without the consent of the tramway shareholders.

VICKERS, SON AND CO. (LIMITED).—The Directors of this Company have declared an interim dividend of 5 per cent. per annum on the Preferred stock.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended August 10th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,219.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 849.—Vol. XXXIII. FRIDAY, AUGUST 24, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

As will be seen by a note in another column, the strenuous opposition of a handful of members has induced the Postmaster-General to defer the signature of the agreement with the National Telephone Company until next session. What can be gained by this delay, except loss of time, it is difficult to see, since by the Telegraph Act of 1892 and the Treasury Minute which heralded it, Parliamentary sanction was given to a certain course, a mistaken one as we think, and no measurable deviation from that course can be made without something approaching a breach of faith. Parliament apparently rather enjoys agreeing in haste and repenting at leisure.

This week we begin to reprint the two important Papers on the Liverpool Overhead Railway, by Mr. Greathead and by Mr. Thomas Parker, which were read before the Institution of Civil Engineers in February last. Not only is this railway of great interest because it is the first permanent elevated electric railway, but because it is a thoroughly practical and financial success. It is, moreover, an example of sound English engineering. Not the smallest hint, so far as we are aware, has been taken from American tramways, though the fact that the carriages are mounted on bogies, and that there is a passage from end to end, has been quite sufficient to start the idea that the whole concern has been copied from American work. If there is a line in America or elsewhere that can be compared with the Liverpool road for completeness, solidity, first cost, or working expenses, we should be interested to hear of it. An attempt was made during the Chicago Exhibition to run a so-called "intramural" railway; but it was only a big side-show, and no figures as to financial success, or even as to cost of working, were ever published. The great glory of it was the colossal dynamo of 2,000 h.p. It may be remembered that soon after the City and South London Electric Railway was opened, numerous designs and schemes for New York lines of exactly the same type were suggested. The estimate for the electrical equipment of the Ninth Avenue Railway of New York, based upon certain experiments made in 1889, was probably deliberately intended for political or other business purposes to mislead; but a comparison with the actual cost of the Liverpool line is amusing, for the six miles of that line has cost little more than 5 per cent. of the estimate for the Ninth Avenue line of five miles.

An interesting example of the mutual help which experiment and calculation afford one another was furnished in Prof. J. J. Thomson's Paper "On the Velocity of the Cathode Rays," which was read before Section A of the British Association. As our readers are probably aware, the medium of the cathode ray has been a matter for considerable debate; one view taken being that the ray is a phenomenon of the ether, similar to electromagnetic radiation, the alternative view being that the ray is produced by molecular streaming. The behaviour of the ray in a magnetic field, however, as Prof. Thomson observes in his Paper, requires that if the ether hypothesis is adopted the ether must be invested with altogether new and startling properties. And, indeed, before the physicist can feel justified in adopting such a modified ether, he must have very conclusive evidence that the cathode ray is not the product of molecular motion. In order to determine whether a stream of electrically-charged gas particles could account for the phenomenon, Prof. Thomson has worked along two distinct lines of investigation, and compared the two results. The first line consisted in experimentally determining the velocity of the cathode ray in the rarefied gas; the second, in calculating what that velocity ought to be if the ray is due to a stream of electrically-charged gas particles urged down a potential gradient. The observed velocity, in the case of a discharge passing through the so-called hydrogen vacuum, was $1{\cdot}9 \times 10^7$cm. per second; and the calculated velocity, under the same conditions, came out at $2{\cdot}0 \times 10^7$cm. per second. The agreement is astonishingly close, and, as Prof. Lodge remarked during the discussion, tends strongly to support the view that this velocity is approximately correct. More than this, the agreement would seem to give great strength to the hypothesis of molecular motion, as contrasted with the ether hypothesis.

We are still, however, face to face with Prof. Schuster's important criticism, namely, that what Prof. Thomson had been directly measuring was the rate at which the cathode ray discharge establishes itself along an axis in space, and not the actual velocity of the molecules past any fixed point on that axis. At first we were inclined to believe that this criticism, if justifiable, must weaken the arguments on Prof. Thomson's side. For there is an obvious difference between the value of measurements made in the initiatory stages of a phenomenon, and those made when the phenomenon is steadily established. In the case of a stream of electrified particles moving down a fixed potential gradient, however, the movement of the very

Digitized by Google

first particle would be exactly repeated by every succeeding particle. In this case, therefore, the conclusions might equally well be drawn from measurements at the initiatory stage as at any later stage. Indeed, the fact that such measurements do agree with the calculated velocity turns Prof. SCHUSTER'S criticism into a further argument in favour of the view that the cathode ray consists in a stream of gas particles projected along a path under steady electric stress.

SHOULD waves of a particular length be known by their predictor's, or by their discoverer's, or, indeed, by any human name? This point was raised by Prof. LODGE during his remarks, at the British Association, upon "Experiments Illustrating Clerk Maxwell's Theory of Light." Prof. LODGE ventured to express his opinion that if HERTZ were alive he would be the first to discourage the appellation "Hertzian" in connection with the electromagnetic waves discovered by him, and would be foremost to advance the claims of MAXWELL to the adjectival vacancy. Maxwellian waves—that was the just and right name by which they should for ever be known. This brought the learned German, Prof. BOLTZMANN, to his feet to utter a loud and emphatic protest against any attempt to poach on HERTZ'S preserves by taking advantage of his modesty. HERTZ was a modest, retiring man, and might too willingly yield the palm to MAXWELL; but MAXWELL had never turned a brand new wave out of his laboratory, while HERTZ had. We confess to a feeling of pleasure when Prof. LODGE decided that the phrase "Hertzian waves" must go, and a compensating feeling of pain when he put "Maxwellian waves" in its place. Why should a particular range of wave-lengths be stamped by any human name? Will not the practice lead to great inconvenience when the entire orchestra of ether waves is filled up? What if we had to call the middle octave in musical instruments the "Jubal notes," or ocean waves of a certain length by the name of some famous warship which they will set synchronously rolling! To do honour to MAXWELL, we may sufficiently recognise his splendid theory and affix his name to it; to pay tribute to HERTZ, we may use his name as an adjective for the particular methods and apparatus which he invented to excite ether waves. But the waves themselves should be hampered neither by the name of the mathematician who predicted them, nor of the experimenter who first produced them, nor, indeed, by any human name.

GLASS apparatus is now being so largely used in some branches of electrical research; and the electro-chemical influence of the constituents of some kinds of glass is of such importance, and so liable to vitiate the results of the experiments, that the information which was afforded on various occasions during the British Association meeting at Oxford as to the electro-chemical properties of glass must have proved useful to many who heard it. In the chemical section Prof. ROBERTS-AUSTEN read a Paper on "The Electrolysis of Glass" in which he showed that some metallic bases, *e.g.*, sodium, may be passed through glass at as low a temperature as 200°C. under electro-chemical stress. During the discussion of Prof. J. J. THOMSON'S Paper on "The Behaviour of Gases with regard to their Electrification, &c.," it was pointed out that the chemical nature of the rarefied gases in the glass apparatus employed in Prof. THOMSON'S experiments might be affected by constituents of the inner layers of glass. Prof. SCHUSTER came forward with a remedy, which had the advantage that he had actually tried it and found it effective. His remedy consisted simply in electrolysing the basic constituents away from the inner surface of the glass, leaving a surface of pure silica. This was done by passing a continuous current from the inner to the outer surface of the glass. The transparency of the glass suffers to some extent, of course, but not sufficiently to interfere with the observations of electrical discharges taking place in the interior.

THE letter from Mr. STEINMETZ, which will be found in our Correspondence columns, is sufficient, for the present, to answer the foolish comments in one of our American contemporaries on our recent notes on the disadvantages of sine curves in alternate-current work. When certain experiments now in progress are completed, we hope to return to the subject.

Cable Interruptions.—No interruptions are recorded this week.

London, Walthamstow and Epping Forest Railway.—The Bill giving the necessary powers for constructing this line has passed both Houses of Parliament.

Cobwebs.—An obscure country newspaper has distinguished itself by discovering an entirely new and original objection to the electric light. It informs its readers that "there is always a large amount of cobwebs where electricity is in use."

Durham College of Science.—Particulars of the courses of instruction in electrical and other branches of engineering, at the Durham College of Science, at Newcastle-on-Tyne, will be found in our advertising columns this week. The mechanical and electrical equipment of the laboratories at this college appears to comprise several useful machines. The session will commence on September 24th.

Postal Telegraph Statistics.—In the recently-presented report of the Postmaster-General it is stated that an addition of 425 telegraph offices at post offices and 248 at railway stations has been made during the year. There are now 9,210 offices from which telegrams may be despatched. The number of messages of all kinds showed an increase of 1·4 per cent. over the business of the previous year.

Long-Distance Telephony.—The Belgian Government has, it is stated, decided to open negotiations with the English Government for the construction of a direct telephone line from London to Brussels viâ Ostend, it being understood that should the negotiations be successful the authorities at Berlin have signified their willingness to consent to a connecting telephone line from Brussels to Berlin.

Electric Lighting Provisional Orders.—In a Parliamentary Paper just published the Board of Trade report that they have granted 24 Electric Lighting Provisional Orders since the date of their Report last year, bringing up the total number of operative orders to 190, of which 118, or 62 per cent., are at present in the hands of municipal authorities. Something like 44 local authorities either have electric lighting stations in operation, or shortly will have.

Artificial Diamonds and the Electric Furnace.—A correspondent of the *Engineer* questions the morality of artificial diamond making by the Moissan process. He is afraid it may lead to "severe injury to individuals, and to South Africa." Patenting would be useless, "as the patent would be infringed in a wholesale manner." Neither could the process be worked secretly, for "the operators would be likely to disappear mysteriously!" All this seems very dreadful, and we sincerely hope M. Moissan will not allow anything so immoral to happen.

Digitized by Google

Electrical Utilisation of the Waters of the Loue.—An agreement has been signed between MM. Ritter et Magnin and the municipal authorities of Besançon by which that town may before long be expected to be blessed with an electric supply at a price 22 per cent. less than that of gas. MM. Ritter et Magnin's concession will be exploited by an influential Franco-Swiss syndicate, and 3,000 H.P. will be electrically transmitted to Besançon, the power being derived from the River Loue between its source and Mouthier, 7,500 H.P. being available on an average, and 3,750 H.P. during the driest season.

Fire at Siemens and Halske's Chicago Factory.—The Chicago factory of the Siemens and Halske Electric Company, of America, was destroyed by fire on the night of August 1st. It is estimated that the loss will amount to £60,000; the insurance was about £22,000. The destruction of the building was complete, and a large amount of machinery which the Company was constructing was utterly ruined. The generators designed for the Toronto Street Railway Company were destroyed. The Company was fortunate in saving its books, drawings, and patterns. The plans of the Company are not announced, but it has not cancelled any of its contracts.

Electrical Utilisation of the Gohna Lake.—According to the latest telegrams the waters of the accidentally formed reservoir in the Himalayas known as the Gohna Lake have now reached within 50ft. or so of the top of the natural dam. The length of the lake is now 4½ miles, its average width ½ mile, and its average depth may be taken at about 500ft., which is also, we believe, about the height of the dam, which is well-nigh vertical. We do not know what could be done with the power if generated; but enthusiasts are not likely to overlook this opportunity of proposing to electrically utilise this heaven-sent reservoir, which contains, roughly speaking, a store of some 25×10^7 H.P.H.

Motor Predetermination.—At a recent meeting of the *Société Internationale des Electriciens*, M. J. Rey described a 720-H.P. electric motor built in the workshops of MM. Sautter, Harlé et Cie., and intended to propel the submarine boat "Gustave Zédé," the motor being a 6-pole machine, with two armatures coupled in parallel, keyed to a common shaft. M. Rey pointed out that the commercial efficiency of the motor, as tested by a modification of the Hopkinson method, came out at 92·44 per cent., the calculated efficiency being 92·15 per cent.; and he laid stress on the fact that in no other branch of engineering would it be possible to predetermine the output of a machine to within less than 1 per cent

Capetown Electric Light Scheme.—The action of the Municipal authorities of Capetown regarding the electric lighting engineer about to be appointed is meeting with some criticism, as will be seen from the following extract of a letter written to a local paper by a Capetown taxpayer:—"I have seen the Municipality's advertisement asking for a triplicate engineer; namely, hydraulic, electric, and steam, competent to control the works now going on for electric light. The result, as was to be foreseen, is that no *bona-fide* applicant has turned up. We shall get the young man from home, of course, at some date. Meanwhile the contract under execution, costing the town £60,000 or over, wants no controlling!"

Islington.—The Vestry of Islington recently appointed a committee to make exhaustive inquiries as to the relative cost of gas and electricity, especially with regard to street lighting. The committee now report that they have been unable to obtain any definite data from actual experience of the relative cost of lighting public streets by the two illuminants. They, however, say they have come to the conclusion that the lighting with arc lamps of the route from the Angel to Finsbury Park —namely, High-street, Upper-street, Holloway-road, as far as the Nag's Head, and thence along Seven Sisters-road to the park—which is projected as a commencement, would cost little (if any) more than the present cost of gas. We hope that this conclusion may be realised, and shall be interested to learn the data on which it is founded.

Books.—Before leaving England Mr. Kapp handed in the final proofs of the fourth edition of his work on the "Electric Transmission of Power" to Messrs. Whittaker. The work has been brought up to date, both as regards theory and practice. Examples of the most recent installations of power transmission by continuous current, including the series arrangement of a number of machines for working at extra high pressure, have been added to or substituted for the examples in the third edition. The theory of continuous current generators and motors has been further developed in accordance with latest investigations, and several new chapters have been added dealing with the transmission of power by simple and multiphase alternating currents. The theory and construction of alternators, transformers, and alternating current motors, has been added, as well as examples of large alternating current plant successfully at work on the Continent. The book contains many illustrations and full particulars of dynamo-electric machinery made by the best English and foreign engineers.

The Paris Municipal Central Station.—In recent issues of *La Lumière Electrique* M. G. Claude has been describing, at infinite length and with infinite pains, the latest phase of the Paris Municipality's central lighting station, which has met so far with but very qualified success. Although Belleville boilers are used it seems that the kilowatt hour cannot be *generated* with an expenditure of less than 10lb. of such coal as they get in Paris; a long way off Mr. Crompton's ideal of 2½lb. of Welsh coal per unit *sold* and his actual of under 5lb. The presence of a storage battery in the station, and the curious use which is made of it, may perhaps supply a clue to this lack of economy in fuel. Electric energy is first of all generated at the rate of 1 kilowatt hour per 10lb. of coal, and stored in accumulators which, according to M. Claude, have a maximum efficiency of 60 per cent. On leaving the accumulators the current passes to a Hutin-Leblanc "panchahuteur" or transformer, where it is converted into a current of the high-pressure alternating species, finally reaching the lamps after the usual losses in the line and step-down transformers. The transformers, according to M. Claude, are so inefficient that the substitution of improved apparatus would lead to an annual saving of £2,100.

"La Lumière Electrique."—We have received the following communication from the editorial office of our Paris contemporary:—Founded on April 15, 1879, *La Lumière Electrique*, a universal journal of electricity, has been for fifteen years the most complete and authentic organ of the science to which it was devoted. It has not hesitated to make any sacrifices to insure its utility, and each year it has resulted in an average loss to its proprietor of more than 70,000 francs, and at the present moment the journal is in difficulties. Two solutions have been considered by the managers: (1) To increase the rate of subscription, and to open the columns of the paper to commercial advertisements; (2) to suspend the publication for a sufficient period to permit of financial reconstruction. The first solution was immediately discarded. *La Lumière Electrique* has never sought pecuniary gain, and it will remain a journal of pure science, and a stranger to all commercial promiscuity. The second solution has therefore been adopted, and it is hoped that subscribers, remembering the past, will be faithful to it in the future, and that they will accept patiently this momentary stoppage. Those subscribers who do not adhere to this proposal will be good enough to communicate with Counsel, M. Francis I. Delasalle, Advocate in the Civil Tribunal of the Seine, 19, Rue d'Alger, Paris.

Electric Welding.—At the Manchester meeting of the Institution of Mechanical Engineers Mr. B. A. Dobson read a Paper on electric welding. As the results of some experiments conducted at the author's works, a number of interesting facts have been arrived at. It has been found that electric welds may be bent cold without giving way, not more than one out of 500 welds proving defective in this respect. The question of cost, which of course is of importance to commercial engineers, has not been alluded to in detail. The author admits, however, that the payment of royalty, the cost of horse-power, and the depreciation—which on electrical apparatus is heavy—together bring the cost considerably over the net cost of the ordinary smith's hearth work; while the actual payments in wages and so on are considerably less. The loss in weight of iron is about one-twentieth only. It may be taken that on straightforward welds the total cost will be between 10 and 15 per cent. more than the ordinary smith's work; whereas, in

Digitized by Google

delicate work and difficult operations such as have been alluded to, the cost will probably be one-third of the smith's work. But the real advantage of the apparatus, at any rate as at present arranged, is not so much an economy as a method of securing an absolutely reliable result, and occasionally saving considerable expenditure by its special adaptability. The amount of power required to effect a large electric weld is very considerable, but the time during which this power is required for each weld is very small. A 2in. wrought-iron bar required from 55 to 59 H.P. for from 243 to 246 seconds, neglecting the power expended in the mains and machinery. A 1in. wrought-iron steam pipe required from 15 to 25·5 H.P. for from 61 to 86 seconds.

The Liveing Explosive Gas Indicator.—In the course of his four Cantor lectures on "the Detection and Estimation of Gas or Vapour in Air," delivered before the Society of Arts, early this year Prof. Clowes briefly described the Liveing indicator. As this ingenious electrical instrument may not be generally known to our readers, the following may be of some interest. The Liveing indicator depends upon the principle that when a mixture of gas and air is passed over an incandescent wire, the wire glows more brightly. In the Liveing apparatus one wire is enclosed in an hermetically closed tube containing pure air, and the other is enclosed in a tube open to the atmosphere to be tested. When an electric current is passed through the wires they will be of equal brilliancy if the atmosphere being tested is pure. The two wires are compared by means of a photometer arrangement, which enables the percentage of fire-damp to be read off on a scale; and the necessary current is generated by means of an electro-magnet arrangement driven by hand. Taking the light of the enclosed wire as unity, the light of the exposed wire has been found to be equal to 1·24 when ¼ per cent. of fire-damp is present; 1·65 with ½ per cent.; 2·78 with 1 per cent.; 5·10 with 2 per cent.; 22·0 with 3 per cent.; and 64·0 with 4 per cent. Mr. James Grundy, of Bolton, who has made a series of check tests with this apparatus, finds that it does not give sufficiently steady results until the proportion of fire-damp has reached 1 per cent.; and he also finds that with use the wires undergo change unequally. The exposed wire increases in electrical resistance, while the other remains practically constant. As this causes the enclosed wire to glow more brightly it becomes necessary to take the instrument into pure air from time to time, in order to readjust the photometer scale. Indeed, in some of his tests Mr. Grundy found that the zero mark upon the scale was, by this change of resistance, shifted beyond the distance between the two wires. The change was curiously fitful in some wires and in others it was rapid, but when it had once taken place the wires could not be brought back to their original condition. There is one other objection to the apparatus, and that is that to get constant results there must be a constant current passing through the wires, which cannot be obtained with a hand-driven generator. It is quite possible, however, that the apparatus may be improved, and one of the most apparent improvements is the introduction of a proper storage battery.

The Government and the National Telephone Company.—The Postmaster-General and the Chancellor of the Exchequer were subjected to considerable "heckling" last week with regard to the proposed agreement with the National Telephone Company. Mr. A. C. Morton asked whether the intention was still to meet, as far as possible, the telephonic views of the municipal authorities, and if so, having regard to the fact that the proposals had only just been circulated, Mr. Morley would postpone until next Session the completion of the agreement, so as to give the municipal authorities an opportunity of expressing their views on it. Mr. Henniker Heaton asked the Postmaster-General whether he would consider the propriety of referring the Treasury minute to a Committee of business men chosen from Members of the House. Mr. A. Morley replied that the Committee which sat in 1892 recommended that the details of the arrangement should be carried out by the department. The agreement did not require the confirmation of Parliament. It merely carried out the policy which had already received Parliamentary sanction, and in connection with which large sums had already been expended. The telegraph estimates would afford an opportunity for any discussion that it might be desired to raise. He was not prepared to assent to the postponement of the matter until next Session. Later on Mr. A. C. Morton asked the Chancellor of the Exchequer whether he intended to force through the draft agreement with the National Telephone Company. So long ago as last November the Postmaster-General promised that a copy of the draft should be circulated before the Government agreed to it, not only amongst members but amongst the municipalities of the country, so that there might be ample opportunity of considering it. If the agreement were concluded, it would be a distinct breach of faith. The Chancellor of the Exchequer replied that if the Government found there was a well-founded opposition to the agreement they would consider whether it could be postponed. Mr. Benn assured the Chancellor of the Exchequer that the feeling on the London County Council with regard to the agreement with the Telephone Company was very strong. They strongly objected to the absence of opportunity for examining its provisions. Mr. Cohen said that, as far as he knew, there had been no expression of opinion by the County Council. Mr. Storey said that many large municipalities would be affected by the agreement. They desired ample time to examine the agreement critically. Mr. A. Morley, in deference to the views expressed by various members, agreed to the postponement of the subject.

The French Press and British Submarine Cables.—In our last number a flat contradiction was given to statements of the French Press, mainly in the *Journal des Debats*, about the action of English telegraph companies in their relation with the Government and the public in France. The *Soleil* of the 13th inst. reproduces the same attacks, and adding further charges with the object of throwing discredit on the Companies' services. "Everywhere," says the writer, "telegrams from French agents reach Paris after long delays and mutilated; the English Press circulates false and prejudicial news before rectification is possible; orders sent from Paris to the French Government agents, to the commanders of French forces, are deciphered, tardily transmitted, and previously communicated to our adversaries. Likewise, as regards the conflict between Siam and France, pending which all the news interesting us were received through English channels and our Government being only informed twenty-four hours after London newspapers." The general remarks embodied in the above are absolutely incorrect, and the Companies oppose a flat denial to the special charge referring to the delay in transmission of messages to France during the difficulties between France and Siam. The Eastern and Eastern Extension Companies, from the commencement forwarded instructions to every station under their control to give their most careful attention to the prompt and accurate transmission of French correspondence, and those Companies may credit themselves with having had those instructions most successfully carried out by their staff as regards the telegraph service on their own lines, as may be fully substantiated by the traffic returns and also as has been fully acknowledged by the French Government itself. It may be pointed out that neither Company has stations in Siam, where the service is performed on one side by French land-lines in connection with Cochin China, and on the other through the Government of India land-lines, as far as Bombay. A large portion of the Government correspondence with Siam was forwarded as far as Hong Kong through the Great Northern Company's lines, which is a Danish Company, and received by the same route. But the Eastern and Eastern Extension Companies affirm, and claim that they can justify the statement, that all French traffic has been transmitted with the utmost speed and the greatest accuracy from the moment it was placed in the hands of their officials until it was delivered at Marseilles to the French telegraph authorities. As the Chairman of the Companies named has frequently said in public "telegraphy knows no politics," and obviously as a matter of business it is to their interest to do their best for all their customers regardless of nationality. The Companies referred to have concessions from and carry telegrams for almost every European Government and people; but it is from France alone that complaints of unfair treatment come.

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(*Continued from page 387.*)

Dip pumps (*see* Fig. 115), should invariably be driven by series-wound motors if continuous currents be used. Centrifugal pumps have generally a limited use in mines on account of requiring to be "primed" before they will suck water, and also because there is always a risk of the pump ceasing to act if air gets into the suction pipe; in fact, they require frequent attention. These pumps are not suitable for working against higher heads than 28ft. or 30ft. of water unless special precautions are provided for starting. They are suitable for a low head and a large volume, and will be found useful in cases where the water is too "dirty" for a force pump. A usual arrangement is shown in Fig. 116.

Fans, either main or auxiliary, should also be driven by series motors, if run off a continuous-current circuit. The electric motor is peculiarly adapted for running fans, and it is somewhat surprising that this has not been recognised more fully. The author designed a 25-H.P. main fan plant for a tin mine at Eger, in Bohemia, in 1889, the dynamo being driven by water power at a distance of about half a mile from the motor.

Coal cutters and rock drills have hitherto, with few exceptions, been run on continuous-current circuits. In order to avoid "racing" when running light both differential compound and shunt windings have been tried with indifferent success—comparative regularity of speed has been gained at the expense of torque. After numerous experiments, the author has found series-wound motors to give the best results for driving coal getters and drills. He prefers to control the speed by an external resistance. Other workers in this field have arrived at the same conclusions. But the success attained has not been sufficient to warrant the hope that coal will be got largely in the future by machinery driven by continuous-current motors.

The future appears to lie with the polyphase systems. The polyphase motor, having neither collector nor brushes, obviates the danger from sparking at the brushes—a difficulty always present with continuous-current motors. And, since the speed can never exceed that of synchronism with the generator, racing is impossible. The regulation of polyphase currents can be accomplished in a small space by means of impedance coils with *no possibility of sparking*, for no part of the circuit need be opened or shunted, as is necessary with a continuous-current resistance regulator.

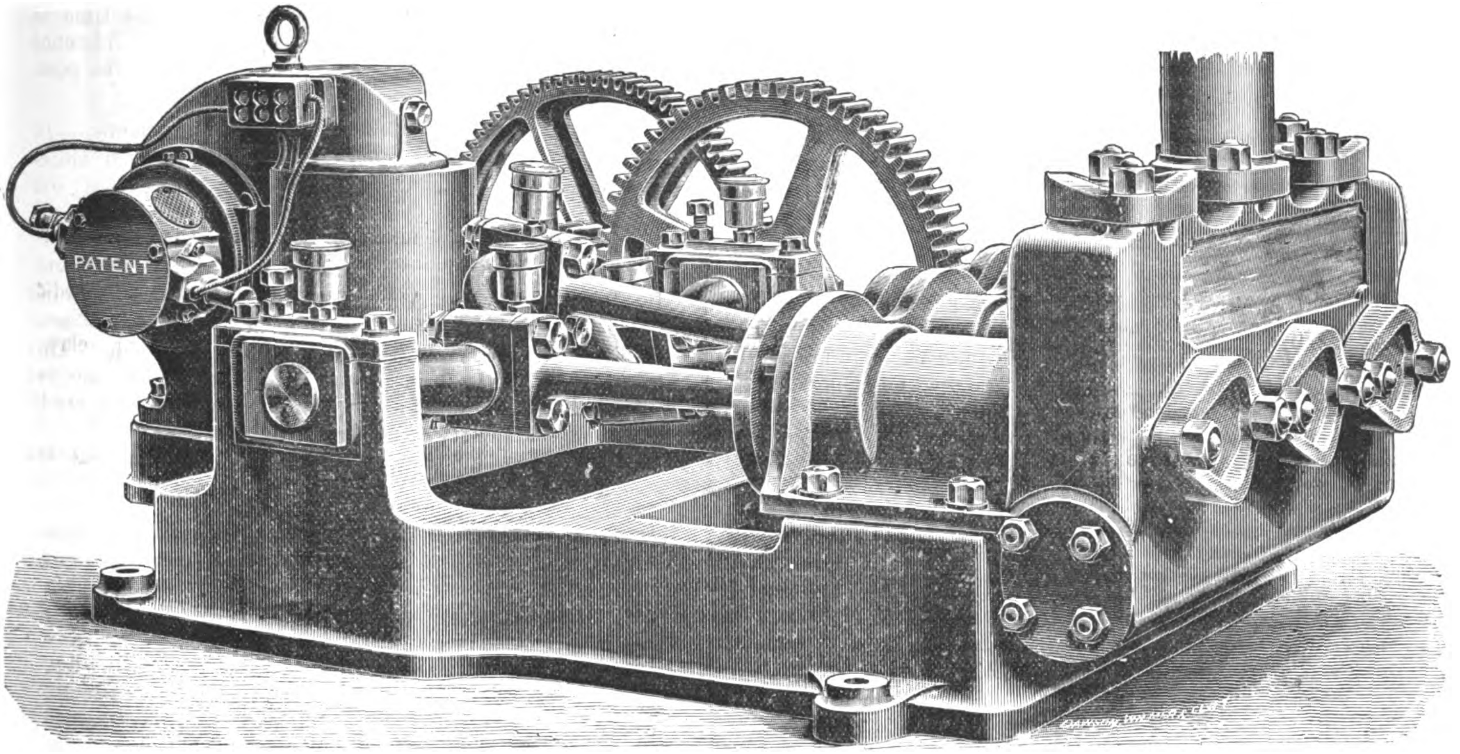

FIG. 115.—Goolden Three-Throw Dip Pumps with Safety Motor, suitable for mounting on a Trolley.

The sole point on which continuous-current motors are superior to polyphase ones, and then only with series winding, is as regards the *starting* torque. From this point of view they are undoubtedly the best and most efficient motors that can be built. The ordinary three-phase motor at starting is roughly comparable to a shunt motor—neither better nor worse.

It is usually possible, however, to start a motor before coupling it to the load if the initial torque be too great for the maximum motive effort. With drilling machines the drill can be slacked if necessary, and with coal-getters the initial torque of the motor can be made sufficiently great to start the cutter against the friction of the debris, which is all that is necessary. A "fall" should be cleared away by hand.

In driving large pumps and hauling gear, it will generally be advisable to use friction clutches, through which the load can be gradually applied after the motor has acquired its proper speed. The clutch does not entail extra expense in most cases, since its use is generally advisable and often absolutely necessary even with continuous-current motors.

Safety Motors.

Attempts have been made to design a continuous-current motor perfectly free from the risk of firing gas from sparks at the commutator, or from short circuits in the coils. It is admitted on all sides that so long as brushes and commutators are used (sliding contacts) it is impossible to work without sparks which, under certain conditions, may fire explosive gas. It is, indeed, found experimentally that the small blue sparks occasionally seen on even the best continuous-current motors are able to fire gas if the metal of the commutator become heated, as it will at times. It is, therefore, necessary to confine the explosion area to as small a space as convenient, in order to limit the effects and prevent communication to the outer air.

The first crude attempts were made in the direction of enclosing the entire motor in a metal case. It was soon found, however, that the quantity of air enclosed was too great to be safely fired, and the method was abandoned. The next obvious course was to inclose only the armature, commutator, and brushes. By suitable arrangements this can be done in a very effective manner, and the space so enclosed can be made small enough to limit an explosion to the protected area. But other

* All rights of reproduction reserved.

Digitized by Google

difficulties are introduced. The design of the brush gear is complicated, and the adjustment of the brushes is rendered exceedingly difficult, especially to unskilled hands. The author has built motors for coal cutting in this manner, and Messrs. Easton, Anderson and Goolden have patented various devices with a similar object.

In Fig. 117 is shown a perspective view of the excellent safety mining motor made by Messrs. Easton, Anderson and Goolden. The general arrangement is easily understood. The armature, commutator, and brushes are encased in a metal compartment, the free space of which is small. The makers say that an explosion of gas within it cannot be communicated to the outer atmosphere. The author has had no opportunity of testing this important statement, but from his knowledge of the motor it appears to be correct, always assuming the casing is in good condition and the inspection doors properly fastened.

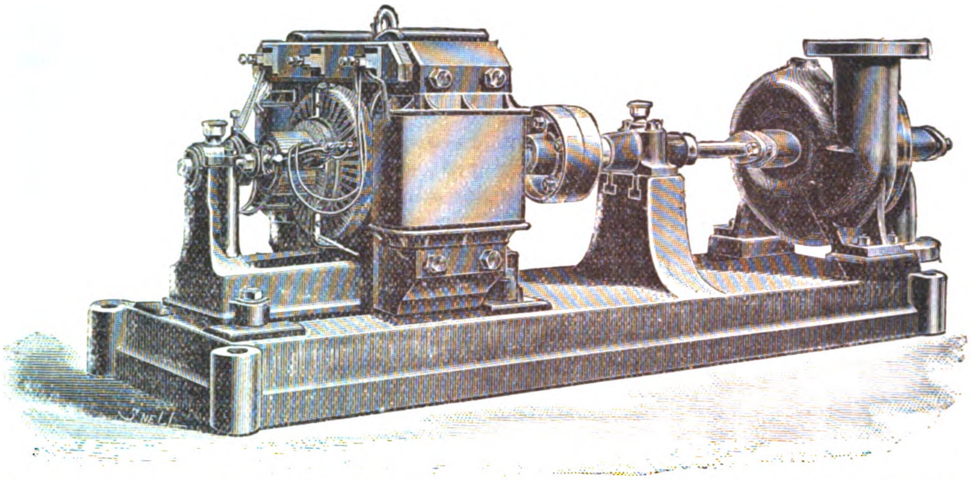

Fig. 116.—General Electric Power and Traction Company's Centrifugal Dip Pump, suitable for mounting on a trolley.

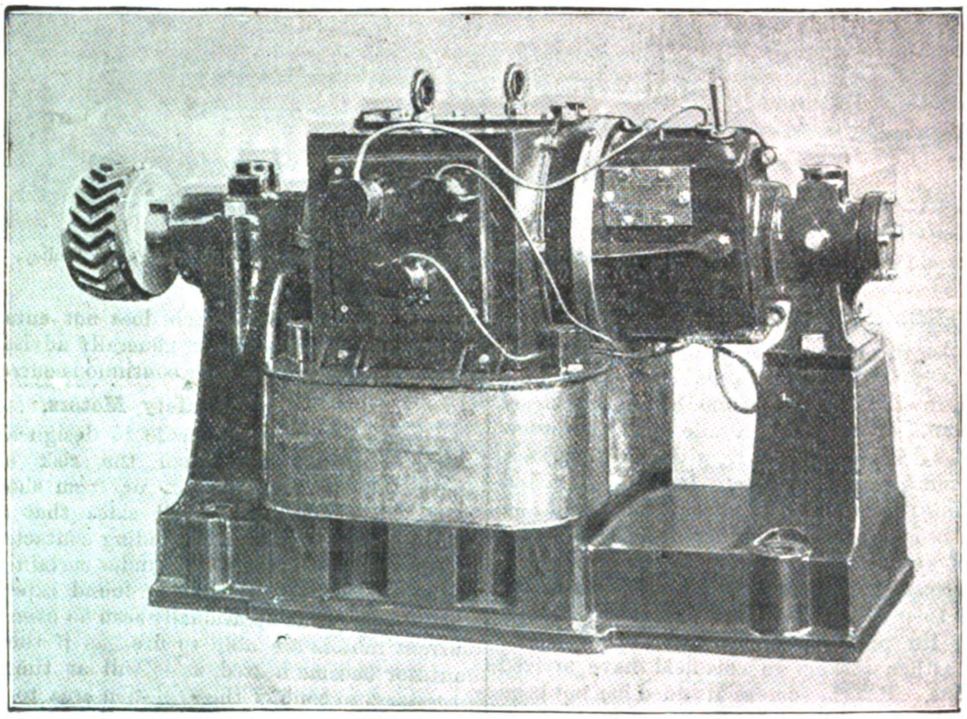

Fig. 117.—Goolden Safety Mining Motor.

Messrs. Davis and Stokes, of Derby, have invented an ingenious "safety motor," a sectional view of part of which is shown in Fig. 118. It will be seen that the commutator is inverted, and the brushes placed inside of it, instead of on the outer perimeter, as is usual. The brush arms are attached to a movable ring, sliding upon the bearing parallel to the shaft, and arranged to lock in the proper running position through a screw collar. The brushes are thus placed in a small circular space inside the commutator, the cubic contents of which in small motors is comparable with that of a safety lamp; and in even large machines can always be made sufficiently small to render an explosion within it quite harmless. It should be noticed that the brushes can only be got at by the attendant when the motor is standing, and, therefore, when there is no chance of danger. Motors of this make have been tested in an explosive mixture of air and gas by Mr. John Rhodes, at Aldwark Main Colliery, who found that, although the gas continually flashed inside the commutator, it did not communicate flame to the outside. This is, perhaps, the safest form of continuous-current motor yet invented, and been successfully used for the past four years in connection with a variety of underground work.

It is questionable, however, whether all of these designs are not chiefly important as dust protectors. (It is absolutely necessary that a motor worked on a coal face should be dust-proof.) Though the cases may fit well when new, they probably soon get loose and defective from the rough usage inseparable from the class of work, and become then useless as safety devices; indeed, they may then be a positive source of danger from the apparent security attached to them.

Digitized by Google

The only real safeguard against explosions from sparking at brushes and commutators (sliding contacts) is to do away with them altogether, and the only way in which this is practicable at present is by the use of polyphase motors. The mechanical simplicity and excellent speed regulation of these machines have already been urged. These advantages, in combination with their safety, must gradually tell. They will necessarily oust all other types of motors for driving coal cutters, rock drills, and other machines which have to be driven in a dusty atmosphere, liable at any moment to be charged with gas.

In the author's judgment, the mining motor of the future will probably present the appearance of a circular iron box. The revolving part will have no electric connection with the supply mains, and will resemble an iron cylinder with closed

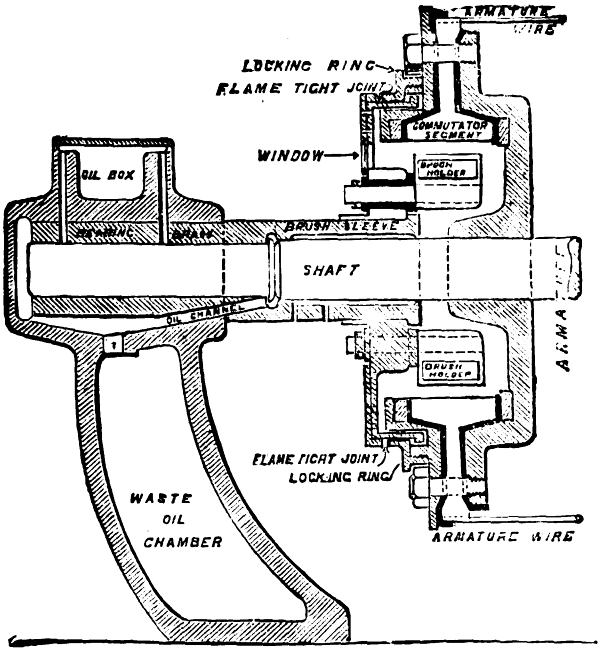

Fig. 118.—Sectional view of Davis and Stokes' Inverted Commutator as used on their Safety Mining Motor.

ends and steel shaft. A breakdown of the insulation inside the cylinder will simply affect the efficiency, *it will not cause sparking*. The windings in connection with the mains will be few in number, wound in recesses, and entirely protected from external damage by means of the outer framework. The conductors will be of the concentric type, and in permanent plants it is probable that the Pownall Safety Mining System, or some development of it, will be generally adopted. The junction boxes, switch, cut-outs, and regulating devices will be all flame-tight, and protected by oil, or air under pressure. An explosion from an inadvertent spark will be a more remote contingency than one from a safety lamp.

(*To be continued.*)

SOME ADVANTAGES OF ALTERNATE CURRENTS.*

BY PROF. SILVANUS P. THOMPSON, D.SC., F.R.S.

Amongst electrical engineers there remain a few, chiefly of the old pioneers, who have not yet grasped the advantages possessed by alternate currents over continuous currents in systems of electric supply. Superstitions still linger that alternate currents are less easy to manage, or are less economical, or are more dangerous, or are less readily measured than continuous currents. There is a special superstition that they cannot drive motors. Such superstitions once set afloat die hard. And, sad to relate, they are sedulously fostered by a few interested persons who ought to know better.

The present Paper is intended to point out a few of the more salient advantages attendant on their use, and to add a few points that have recently claimed the writer's consideration, and are not yet generally known.

It is well known that the economic transmission to a distance of electric energy depends for its success on the use of high voltages or pressure. The reason is that power depends on the product of two factors—current and pressure, and that of these two factors the former, current, involves some waste in the conductors. If large currents are transmitted at low pressures there will either be much power wasted as useless heat in the copper conductors, or else the conductors must have such large cross-section that the interest on their prime cost involves a still more serious waste. If small currents are used at high pressures—1,000 volts, 5,000 volts, 10,000 volts, as the case may be—the copper conductors may be small, and the interest on their cost a trifling quantity.

Now, this all-important fact to the electrical engineer is absolutely independent of the nature of the current as to whether it is continuous or alternating. The advantage of alternating over continuous currents comes in in the circumstance that high pressures cannot be used in houses without being transformed down to low pressures. Hence the system which admits of transformation by a stationary transformer, consisting merely of two coils wound upon a common core, is to be preferred over one that requires running machinery for transformation.

Again, it is an advantage, not only for high-voltage systems as distinguished from low, but in all systems, whether high or low, in which currents of considerable magnitude have to be collected and delivered, that there should be no necessity for employing either in the generating plant or in motors any commutators, or sliding contacts, with their adjustable brushes, and the like paraphernalia. The commutator—the indispensable adjunct of the continuous-current dynamo and motor—has long been known to be its weakest part from the engineering point of view. It is complex and costly as compared with other parts. It requires far more attention than any other part of the machine. It undergoes greater wear; and the circumstance that under conditions not far removed from normal it may give rise to serious sparking is also a disadvantage. Alternate-current generators have no commutators. Those types of alternator in which the armature revolves require indeed collecting rings (for sliding contacts) and brushes; a device to which the foregoing remarks on commutators scarcely apply, seeing they need no adjustments nor give rise to sparks. But the types of alternator now coming most in favour do not even require these (except on the exciting circuits where their disadvantages are nil), since in them the high-voltage armature parts are stationary. The only parts that need revolve are most substantial masses of iron and copper needing no special insulation in their construction, or attention in their operation. To be spared all the troubles arising from commutators and brushes is no small advantage in itself to the central station engineer.

Another advantage of an entirely different character is the greater safety of alternate currents. With them there is far less likelihood of trouble from leaks in the distributing circuit than if continuous currents were used at the same voltage. This arises from the circumstance that the electrolytic action of the alternate current is so extremely small. If there is a weak point in the insulation of a main or branch conductor, where damp can get in to form a path for leakage, the continuous current will find it out and promptly set up chemical corrosion. Corrosion, sooner or later, ends in setting up an arc, and an outbreak of fire results. The corrosions of water and gas-pipes complained of in many districts where a continuous-current supply is maintained, are unknown where alternate currents are used. The danger to life for equal voltages is, I think, now established to be greater with continuous currents than with alternating, as their destructive action on the tissues is greater.

Again, it is no light matter that while in a continuous-current supply there is but one way of moderating or regulating the strength of the current which flows to a lamp or motor from the supply mains at a given pressure, there are two modes of regulation possible if the supply be one with alternating currents. In the continuous current case we regulate by introducing resistances which regulate by wasting power. It

* Paper read before the British Association at Oxford, Section G.

Digitized by Google

is as though, when we wanted to put a slow speed on to a power lathe, we did it, not by changing the gearing, but by putting a grindstone on the same piece of shafting, and slowed it down by grinding something that would waste the power. But in the case of alternate currents—though we may still, if we please, regulate by wasteful means—we have another and non-wasteful way available in regulation—namely, the use of so-called *choking coils* or *reactance coils*—which operate by setting up opposing electromotive forces in a purely automatic way, damming back the currents instead of wasting them. The use of choking coils is destined to find a very great increase in services of this kind.

It would be travelling too far from the range of this Paper to enter to any great length upon the work that has been done during the past five or six years with combinations of two, three, or more alternate currents in different phases. Two-phase and three-phase combinations of alternate currents, using three or four wires for their transmission, instead of the ordinary two-wire system of conductors, are now quite well known, and their advantages in special cases are fully recognised. Of course, it will be at once replied that any phase-system of currents that is a combination of two or three alternate currents, and requires three or four wires instead of two, cannot be entirely an advantageous system as compared with simple continuous currents, being more complicated. This is very obvious; and yet the fact remains that with two-phase and three-phase systems of currents one can accomplish results which the simpler systems cannot accomplish, and meet conditions which the simpler systems cannot meet. Without attempting any complete exposition of the phasal systems, let one or two points suffice for remark. It has been found essential, or at least advantageous in those districts where continuous currents are used on a large scale, to depart from the sweet simplicity of the two-wire system, and, in order to economise in the total cost of copper in the mains, to adopt a three-wire, or a four-wire, or even a five-wire distribution, so that sweet simplicity is not always on the side of continuous currents. Again, if a three-wire three-phase system of alternate currents is used, the total weight of copper needed in the conductors (at equal voltage) is less than in the ordinary two-wire system for an equal amount of power, whether that two-wire system be with continuous currents or with alternate currents. The main advantage of three-wire polyphase alternate-current systems (whether three-phase or two-phase) is, however, the greater facility that they offer in the handling of motors, since they are more readily made self-starting than is the case when merely single alternating currents are supplied on a two-wire system of distribution.

At the Electrical Congress of Chicago, in the debate on a Paper by Mr. Scott, of the Westinghouse Company, upon polyphase systems, the writer expressed the opinion that, while a polyphase system was adopted to the case of the transmission of power from a single generator to a single motor, in the generality of cases in which the power was to be not only transmitted, but distributed to a number of motors at independent points, the greater simplicity of the simple alternating current would render it preferable now that self-starting motors were in the market. Bearing, however, in mind the advantages to be derived in the possibility of using two and three phase motors, the author gave considerable thought during the winter to the problems of transformation, and particularly to the question whether it might not be possible to transform alternating currents from two-phase to three-phase, or from either of these to single phase, or *vice versâ*. No mode of doing this was known save by the combination of moto-generators as running machines. As one result of his cogitations, he found that such transformations might be readily be effected by stationary transformers, or, in the least easy case, by stationary transformers with a revolving iron core. The simplest case—that of transforming three-phase currents into two-phase, or *vice versâ*—involved no moving parts, being effected by using a ring-coil (or its magnetic equivalent) with connections made appropriately. A simple ring transformer (without revolving core) was shown by the author at his lecture on the transformations of electric currents, at the Royal Institution, on February 23, 1894. It is of some interest to note that on March 7th Mr. Scott read an elaborate Paper to the American Institution of Electrical Engineers, in which he gave an independent solution to the very same problem, using two sets of windings (instead of one), but working out in detail many possible applications.

It is no exaggeration to say that an electrical engineer, starting, let us say, with three-phase alternate currents as the method of supply, is in a position to furnish any customer who may desire either two-phase currents or single-phase currents with what he desires by merely putting in a small appropriately connected transformer.

Another advantage, about which even electrical engineers are as yet almost wholly unenlightened, arises in the application of alternate currents to electro-magnets. Great as have been the services of electro-magnets, as used with continuous currents since their invention in 1825, they are destined to fulfil wider services than ever in practical problems of an electro-mechanical nature now that their properties, when supplied with alternate currents, are becoming known. In 1887 Prof. Elihu Thomson discovered a number of singular properties of alternate-current magnets in producing repulsion of copper discs, and rotation of cylinders and balls by reason of the eddy-currents induced in them. During the past winter the author has been studying the design, construction, and properties of alternate-current magnets, and recently, in conjunction with his assistant, Mr. Miles Walker, read a Paper on the subject before the Physical Society of London. A few words on this topic will emphasise the advantages offered by alternate currents in this application. It has long been known that the magnetic forces of a magnet fall off very rapidly at small distances from their poles. For steel magnets, in those cases in which the poles can be considered as points, the force falls off inversely as the square of the distance, other things being equal. In the case of soft iron electro-magnets operated by continuous currents, the pull on their armatures falls off much more rapidly than this. The forces when in contact may be relatively enormous, and yet the magnet may have no range of attraction worthy of mention. A pull of 150lb. in contact may dwindle to a few ounces at a distance of a couple of inches.

But with alternate currents supplied at constant voltage from the mains, the author finds all this to be different. With a properly-designed and well-constructed electro-magnet, the pull on its armature can be kept fairly constant over a considerable range; nay, in some cases can be caused to be *greater at a distance than when near*. For example, the author has lately had an alternate-current magnet constructed for him by Mr. Walker, the pull of which, when excited at 50 volts, was 8oz., when the armature was closely in contact with the core; but which exercised a pull of 32oz. when the space between them was 3 inches. This obviously introduces into electric mechanism a new element hitherto undreamed of.

The secret of these things is that in the case of alternate-current electro-magnets, the self-inductive reaction of the system, and not the mere electric *resistance* of the wires, is that which governs the flow of current. Whereas Ohm's well-known law for continuous currents is

$$\text{Current} = \frac{\text{electromotive-force}}{\text{resistance}} \text{ or } C = \frac{E}{R},$$

The rule that governs the alternate current in these cases is different, being

$$\text{Current} = \frac{\text{electromotive-force}}{\text{reactance}} \text{ or } C = \frac{E}{pL},$$

where p is the *pulsation* of the alternate current (*i.e.*, the number of radians per second in the revolution of the circle of reference) and L the inductance.

As the armature of the alternate-current magnet is withdrawn from the core the reactance diminishes and more current flows, making the pull greater at a distance instead of less.

Another curious point about alternate-current magnets relates to their winding. In the case of electro-magnets supplied with continuous currents it is well known that the more turns of wire that are wound on the core, the more powerfully is it magnetised. But with alternate-current magnets this is not so. There is one particular number of

Digitized by Google

windings for each magnet, generally a small number, for which the magnetism is a maximum, and any additional wire wound on above this number *diminishes* instead of increasing the magnetic power.

Returning from this digression respecting magnets to the general question of the supply of alternate currents, the author has finally to point out one further set of advantages hitherto both neglected and unknown in this country, though known to a few, and actually in use in the United States.

One of the difficulties which beset the distribution of electric currents on the large scale, is that of maintaining constant, at all points of the network of conductors, the voltage, or pressure, at which the current is delivered to the consumers. Between the generating station and the centre of distribution there occurs a loss of pressure (comparable to the loss of head in the case of water-power) and, beyond the centre of distribution, between it and the points of consumption, in the house lamps, there is a further drop in the voltage. The former drop in the voltage can be compensated for by due arrangements at the central station, but the further drop between the distributing centre and the consumers' houses, though it may be guessed at and partially compensated by some system of over-compensating at the distributing centre, cannot be accurately compensated. The result is that the consumers' lamps do not receive their supplies of current at an unvarying pressure. Now, in the case of continuous-current distribution, the only cause for drop in the voltage at distant points is the resistance offered by the conducting wires leading to those points. The drop due to such resistance—or ohmic drop—is proportional to the ohms of resistance and to the amperes of current. Suppose a group of lamps requiring 20 amperes at some outlying point, the wires to which have a total resistance of only $\frac{1}{10}$th of 1 ohm. The drop in voltage due to the ohmic resistance will be $20 \times \frac{1}{10} = 2$ volts. The lamps, which ought to receive their currents at a pressure of 1,000 volts only receive it at 98, and burn dimly in consequence. But in the case of alternating currents there is a second or additional cause of drop, which has hitherto been held to be a serious disadvantage in their use, namely, a drop due to the self-inductive action of the lines reacting and setting up back-electromotive force, and tending to choke the current. In general, this second or inductive drop is not serious, the mains and branches being arranged concentrically for the purpose of avoiding it as far as possible. But it may become serious when motors as well as lamps are employed upon the circuit, because of the considerable inductive reactions that are set up in the electromagnetic operations of these machines.

Alternate-current motors are of many sorts, but may be grouped under two chief classes, the synchronous and the asynchronous. Synchronous motors are those which only run at one fixed speed—determined for them irrespective of their load—a speed determined solely by the number of their own poles and the number of the alternations imposed upon the current by the generating machinery at the station. They must either run in synchronism with the pulsations of the current, or else not run at all. The other class, the asynchronous, are mostly polyphase machines requiring two-phase or three-phase currents to operate them. The phase currents, led into a suitable armature, there combine to produce a rotating magnetic field, and in this rotating field masses of iron or iron carrying closed circuits of copper are set into rotation, being magnetised inductively, and dragged round by the reaction of the eddy-currents induced in them. The rotor, or rotating part of the asynchronous motor, may be regarded as a revolving field-magnet, not magnetised by any special exciter, or initially, but magnetised only by the eddy-currents induced in it. Now, if it could spin at the same rate as the revolving magnetic field that surrounds it, there would be no relative motion, no eddy-currents, no reactions, and no driving force. It is driven by forces which depend for their existence upon the rotation not being synchronous with the pulsations of the currents in the circuits. Within certain limits it adjusts its speed so that its magnetic slip is proportional to the turning moment which it is called upon to exert.

Now, owing to these necessary reactions the asynchronous motors produce upon the mains which supply them an inductive drop, and cause the pulsations of current to lag in phase behind the impressed pulsations of voltage. Whereas the ohmic drop is not accompanied by any lag of phase in the current, the inductive drop is so accompanied. Happily, with alternate currents there exists more than one remedy. It has long been known that a condenser exercises a reaction of another kind, which, though it tends to choke the currents, does so not by retarding the phase of the pulsation, but by accelerating it. This precious property has long been known and used in submarine telegraphy to compensate, by the use of condensers, the retardations of the signals. But to apply condensers to systems of alternate current supply for the purpose of counteracting the inductive drop when motors are used would be a rather formidable task—the remedy is too heroic for the malady.

A remedy of a different kind is, however, possible, and must before long become general when its advantages are known. To explain it we must return to the subject of synchronous motors, about which little has been said. It was shown in 1868 by Wilde, and in 1879 by Hopkinson, that two alternate current machines could run together synchronously, one as generator, the other as motor, the one which served as motor adjusting itself so that its pulsations of electromotive force tended (as in all motors) to oppose those of the impressed electromotive force. In 1884 Dr. Hopkinson further predicted that an alternate current machine could run as motor, even if its mean electromotive force was higher than that of the circuit, a result verified in practice by Mr. Mordey in 1890. In 1892 Mr. Mordey gave at the Institution of Electrical Engineers some further results of alternate current working, including a very remarkable curve, showing the dependence of the armature current upon the excitation of the field magnets of the motor when loaded with a given load. To this curve and its meaning the author directed attention at the time, and he has since given much thought to it. It will be found to be most significant. The curve presents the form of a letter **V**. The lowest point corresponds to a particular state of things; namely, that the motor having its magnetism excited to a particular degree, draws a certain minimum amount of current from the mains in order to drive its mechanical load at the speed imposed upon it. But, to do the same work—drive the same load at the same speed—will take more current from the mains if the excitation of the magnets is either more or less than this particular amount. This seems very strange; but the explanation and its consequences are no less so. The particular stage of excitation which makes the armature current a minimum for the particular load in question is that stage which corresponds to there being no difference of phase between the pulsations of impressed voltage and those of the resulting current. Suppose, for example, the armature had a resistance of $\frac{1}{2}$ ohm, and that the current was supplied at 100 volts, and that a current of 10 amperes was found to be the minimum current that would drive the load, it would be found (approximately) that the excitation corresponding to this minimum current would be such as would make the motor work with a back electromotive force of 95 volts; for then, by Ohm's law, $(100 - 95) \div \frac{1}{2} = 10$ amperes. But, now, suppose the excitation is lessened, the machine acting at the same unalterable speed will generate less than 95 volts; suppose it drops to 90 volts. Then, if nothing else happened, the current would increase to $(100 - 90) \div \frac{1}{2} = 40$ amperes. But 40 amperes at 90 volts is much more power than 20 amperes at 95 volts, and is more than is wanted for the load—what must happen? The machine is synchronous, and cannot—physically cannot—run faster, so as to take up this power. It tries to do so, with the result that it shifts the phase of its reactions, the current now lagging in phase behind the impressed electromotive force—choked down, in fact, from the 40 amperes to something more than 20—choked down, in fact, to such an amount as would, if multiplied by the cosine of the angle of lag, and by the 90 volts, come up to the same product as the original volts and amperes, namely, $95 \times 10 = 950$. The synchronous motor, *if under-excited*, acts then as a choking coil, producing a reactive drop. But continue the argument the other way: Suppose the excitation is increased so that the 95 volts become 100 volts $(100 - 100) \div \frac{1}{2} = 0$; and there would

Digitized by Google

be current at all to drive did not again an adjustment of phases come into play. Instead of the current dropping to zero, more current than before now comes into play, and that current has its pulsations in advance of those of the impressed voltage, there being now an angle of *lead* in the phase relations. In other words, the synchronous alternating motor, *if over-excited*, acts as a condenser, and, instead of producing a drop in the voltage, tends to raise it by compensating the inductive drops due to self-induction in other parts of the circuit. When the importance of this deduction from Mr. Mordey's curve dawned upon the author he began to prepare to test it upon the mains of the City of London Electric Lighting Company. But before any experiments could be even arranged, he learned that the same conclusions had been arrived at by the officials of the General Electric Company, at Lynn, Massachusetts, and that they had found it in practice to work out favourably. By the courtesy of Mr. W. F. Parshall, one of the engineers of that Company, who has been associated for long with Prof. Elihu Thomson, Mr. Steinmetz, and other engineers, the author is able to state the following particulars: They found that in a line where self-induction played the part of choking coil, it did not matter very much whether the voltage needed for driving the current through the line and machines were situated mainly in the generator or in the motor, as the mean voltage in the line was not far from a mean between that of the two. Accordingly, in a three-phase power transmission at Hartford, Connecticut, of 300 kilowatt output, the motor was arranged to be over excited. Later, after Mr. Steinmetz had submitted the question to calculation, this feature was introduced into the synchronous motors used in all their recent power transmissions, so that by proportioning the armature reaction and the over-excitation to the self-induction likely to arise, the voltages on the circuit remain quite constant regardless of load within the limits of the capacity of the machines. In thanking Mr. Parshall for this information, I may add two points of comment. The advantage so to be derived from over-excitation have indirectly another advantage—namely, that for single transmission cases the motor and the generator may be designed and constructed as identical machines, instead of the motor being made smaller than the generator. Further, the regulation of the voltages in such a network as that of the City of London Electric Lighting Company, instead of being made more difficult when motors are much used—as was feared by some engineers—will be more easy, provided the motors are of the over-excited synchronous type. For the acceleration of phase these produce in the current not only tends to compensate for the inductive drop in mains and transformers, but tends to react right back through the system to the generators in the central station, acting on them as a compound-winding would do, and assisting them not only to counteract the inductive drop, but also the ohmic drop, both between the consumers' lamps and the distributing points, and also between these points and the generating station.

So manifest is this advantage that it would seem worth while to erect at one, or possibly more, points of the network, as remote as possible from the generating station, synchronous motors over-excited, to act as condensers in compensating the inductive drop; or in the primary circuit also, to furnish the idle currents for magnetising the transformer primaries.

With such possibilities open in the future for alternate-current working, and with such advantages in respect of motive power, over continuous-current working, it can hardly be doubted that, save in a few special cases, the vast majority of central stations will henceforth be operated by alternate currents.

ON THE CONSTRUCTION OF DELICATE GALVANOMETERS.*

BY ARTHUR SCHUSTER, F.R.S.

Several attempts have recently been made to increase the sensitiveness of galvanometers; but I have not seen any calculations on the limits which it is possible to reach, or on the advantages gained by winding in the theoretically best manner.

* Paper read before the British Association at Oxford Section A

Maxwell has shown how a coil would have to be wound, so as to give the maximum magnetic field for a given current. A certain space must be left free at the centre of the coil, so as to make room for the magnetic needle, and the sensitiveness will depend on the form and dimensions of this space. We may take the case of a spherical or cylindrical cavity, as these lend themselves most easily to a numerical calculation.

Let the following notation be adopted:—

G = the magnetic force at the centre of the coil for unit current.

R = the total resistance of the galvanometer.

ρ = the specific resistance of the wire used.

a = the radius of the spherical or cylindrical cavity in which the magnet is suspended.

β = the ratio of the diameter of the wire without its insulating covering to the diameter of the wire without that covering.

Then, for a galvanometer wound in the best possible way with a spherical cavity, I find

$$\frac{G^2}{R} = \frac{2\pi^2}{3}\,\frac{\beta^2}{\rho a} = 6{\cdot}58 \times \frac{\beta^2}{\rho a};$$

for a cylindrical cavity

$$\frac{G^2}{R} = \frac{3\pi^3}{16}\,\frac{\beta^2}{\rho a} = 5{\cdot}81 \times \frac{\beta^2}{\rho a}.$$

It has been assumed in the calculation that, with the exception of the cavity, all space is filled with windings, the outer layers contributing, of course, very little to the result. In practice the most important case is the one in which the groove in which the windings are laid has a rectangular section. Weber has calculated the best dimensions for such a groove, assuming the wire to be uniform throughout, and neglecting the thickness of the covering. With Weber's dimensions I find

$$\frac{G^2}{R} = 3{\cdot}22 \times \frac{1}{\rho a}.$$

If the groove is rectangular, and the wire of the same thickness along each layer, but different in different layers so as to give the best result, I calculate

$$\frac{G^2}{R} = 3{\cdot}97\,\frac{\beta^2}{\rho a}.$$

In the last case the length of the cylinder on which the wire is wound should be nearly twice its diameter.

In some of the very delicate galvanometers which have recently been constructed attention was paid chiefly to making the moment of inertia of the suspended parts as small as possible, so as to be able to render the system more astatic without the time of vibration becoming too great.

As regards the magnets there is no doubt a great advantage gained if they are made short and light; but in one galvanometer which I have examined much of the good that was done by reducing the weight of the magnets was undone by reducing too much the size of the mirror. The angle, which can be read off by means of a mirror galvanometer, is proportional to its width. The small mirrors of only about 3mm. width, which are used, are difficult to obtain with a good surface, and it seems to me to be better to risk even a small increase in the time of vibration, if we can read the deviations of the galvanometer with greater accuracy. If the magnetic system is made up of a sufficient number of short magnets placed side by side, the magnetic moment may be increased almost in the same ratio as the moment of inertia, so that we may secure a short time of vibration, together with a mass sufficiently great to allow us to attach a mirror of one centimetre width without materially increasing the period. . . . The weight of the mirror may be reduced by diminishing the vertical dimension, which does not take away from the resolving power.

In order to give an idea of the smallest current which we may expect to detect with a galvanometer of given construction, I have put together a few examples. I take the smallest angle, which is readable with a mirror of diameter d, to be $\lambda/2d$, where λ is the wave-length.

We may, for the purpose of comparison, take the case of a galvanometer wound with copper wire, having one ohm resistance and neglect the thickness of the covering material. If

Digitized by Google

we take a mirror of one centimetre width and let the cylindrical or spherical space left free for the suspended parts have to also a diameter of one centimetre, if, further, the earth's horizontal force is taken as 0·17, the smallest readable current in amperes is, with a non-astatic system of magnets, as follows:

Description of galvometer.	Smallest current in amperes.
A galvanometer with spherical cavity wound in the best possible way	$1·50 \times 10^{-8}$
A galvanometer with cylindrical cavity wound in the best possible way	$1·60 \times 10^{-8}$
A galvanometer with bobbin of rectangular section, and wire of uniform thickness the dimensions of the bobbin being the most favourable	$2·14 \times 10^{-8}$
A galvanometer with bobbin of rectangular section, and wire of variable thickness wound in the best possible way	$2·00 \times 10^{-8}$

The advantage gained by winding with wire of varying density is, therefore, not very marked.

If the dimensions are altered, we may say that the sensitiveness increases inversely as the square root of the cavity, directly as square root of the resistance and as the width of the reflecting mirror. It will not be convenient, however, to increase the width of the mirror beyond one centimetre, as it would be inconvenient in that case to apply sufficient magnifying power to make full use of the aperture, even if sufficiently perfect and light mirrors could be obtained.

THE EQUALITY OF THE VELOCITIES OF PROPAGATION OF VERY SHORT ELECTRIC WAVES IN FREE SPACE AND ALONG CONDUCTORS.*

BY M. DUFOUR.

The equality of the speeds of propagation of electric waves in free space and along conducting wires has been established by MM. Sarasin and de la Rive † for waves between 80cm. and 8m. Hertz had already ascertained the equality of the two velocities for wave lengths of about 30cm.‡ My research was made with a view of seeing whether this equality persisted for still shorter wave lengths.

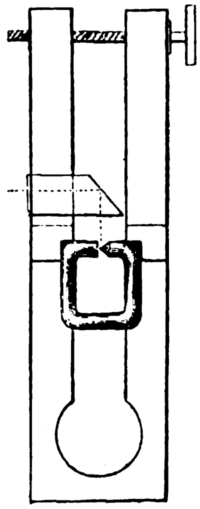
The exciter which I made use of consisted of four copper spheres 2·5cm. in diameter, the centres of which were on a straight horizontal line, and about 2·8cm § apart. They were immersed in vaseline oil. The two outside spheres were connected to the poles of a Holz machine by wires enclosed in tubes of thick india-rubber. Sparks pass between the balls, and the exciter works like that of M. Righi ;¶ it gives rise to electric waves which are propagated in free space. When one wishes to investigate the propagation of waves along conductors, two little copper plates, from which the line wires start, are placed in the vaseline opposite the two middle spheres.

The resonator was a square frame made out of a piece of thick copper wire, the spark gap being in the middle of one of the sides. One of the terminals was pointed, the other rounded (*see* figure); their distance apart was diminished by giving the frame a slight bend. To effect this the portion near the spark gap was fixed, as shown in the figure, near the centre of the arms of a sort of wooden compass, the elasticity of which tended to pull the terminals apart, and they were closed up by a screw which acted on the ends of the arms of the compass, and permitted of a very delicate adjustment. Finally, by means of a total reflection prism suitably arranged the observer was able to see the sparks without being obliged to place his head in the field. The construction and adjustment of square resonators becoming impracticable when the dimensions are very small, I had recourse in studying very short wave-lengths to circular resonators formed by a strip of copper.

In order to determine the wave-length of a resonator in free air, it was arranged vertically (with the spark gap either at top or bottom) between the exciter and the sheet of copper 35cm. by 38cm., which acted as the reflecting mirror. When this sheet was moved the secondary sparks stopped and started. The positions of the mirror at which the sparks disappeared as the node was approached first in one direction and then in the other was noted. As the adjustment was improved the distance between these non-sparking positions was reduced, and the mean was taken as the position of the node. In this way several successive nodes were determined.*

In experimenting with conducting wires I stretched these parallel to one another in an horizontal plane. The resonator was arranged between them in the same plane, so that the spark gap was equidistant from the two wires. A conducting bridge was displaced along the wires, and the position of the nodes was determined as before.

I worked with six resonators; the resonators I., II., III. were made of 0·85cm. copper wire, the sides of the squares being respectively 6·5cm., 4·4cm., and 3·2cm. Resonator IV. was of 0·5cm. wire, the sides being 2·1cm. in length. Resonator V. was circular; it was of copper strip 0·2cm. thick and 0·55cm. wide; the circle was 2cm. in diameter. Resonator VI. was also circular; its diameter was 1·2cm., the copper strip being 0·2cm. thick and 0·9cm. wide. The first column of the following table gives the number of the resonator, the second the wave-length in free space; the third, under the heading of "Distance of extinction," gives the



mean distance of the two non-sparking positions near the node; the fourth and fifth columns give the corresponding values when the waves are propagated along wires:—

Resonator.	λ (free space).	Distance of extinction.	λ (wires).	Distance of extinction.
	cm.	cm.	cm.	cm.
I.	58·0	4·0	57·0	3·0
II.	40·0	4·0	40·5	3·0
III.	21·0	3·0	20·5	3·0
IV.	16·0	2·0	16·0	2·0
V.	13·0	1·5	13·0	2·0
VI.	8·5	1·3	8·5	.. †

I repeated the measurement of the wave-lengths of several of these resonators in free space and along wires, making use of a smaller exciter composed of four spheres 1·3cm. in diameter. The effects were more feeble, and the measurement of the internode less precise; but I observed no variation whatever in the wave-length.

In conclusion I may remark that my investigations allow us to extend the assertion of MM. Sarasin and de la Rive to wave-lengths as small as 8·5cm. The velocities of propagation in free space and along conductors remain the same for small wave-lengths.‡

‡ *Untersuchungen über die Ausbreitung der Elektrischen Kraft*, p. 19.

§ There is an advantage in separating the spheres as much as possible, since the intensity of the effects produced by the exciter increases with the distance separating the spheres.

¶ A. Righi. *Atti della Reale Accademia dei Lincei*, 5th Series, Vol. II., p. 505 (1893).

* The smallness of the secondary sparks rendered micrometer methods, and the measurement of the intensity of the field by the length of the sparks, inapplicable. I only made use of the method of the extinction and the rekindling of the sparks in determining the internode. I arranged the resonator parallel to the mirror, because in this position the sparks are more powerful than when it is arranged horizontally. It should not be either too far from nor too close to the exciter; in the one case the phenomena would be too feeble, in the other the direct influence of the source would predominate.

† Resonator VI., placed close to the wires, only sparked when in the immediate vicinity of the antinodes. The wave-length given in the table is the distance between the two positions of the bridge corresponding to the first and third antinodes.

‡ Investigation carried out in the Physical Laboratory of the Science Faculty of Nancy.

STEEL-PLATE PORTRAITS

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; and Dr. Heinrich Hertz, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

IN PRAISE OF ALTERNATING CURRENTS.

Amongst electrical engineers there remain few who have not yet grasped the fact that under certain disadvantageous circumstances there is no choice but alternating currents or nothing. Herein lies the merit of this system: that it can manage to serve a straggling or poor district with more or less satisfaction to consumers, profits to shareholders, and some day, no doubt, reduction of rates to ratepayers. The Paper read before Section G by Prof. SILVANUS P. THOMPSON, and which we print elsewhere, assumes that the alternate *v.* continuous current controversy is at an end. In a sense this is true enough, but not, as he would tell us, because continuous currents have no chance. The question really is: at what point must continuous current be dropped? This admits of two answers; the one a simple question of radius, fixed by Dr. FLEMING at about one mile of feeder—that is to say, about one and a-quarter mile radius of supply; or it may be treated from the point of view of lamp density over a district, as at Bournemouth, where the successive houses are hardly within sight of each other. No careful comparison of economies, or analysis of losses was put forward by Prof. THOMPSON to aid the decision which has day by day and town by town to be made by impartial consulting engineers; but, putting aside all the real success that has been made with continuous currents, he proceeded to recite "the more salient advantages" of alternating currents, and began with a cleverly worded sentence which seems, unless carefully examined, to imply that these advantages so largely preponderate that none but a few old duffers think that any choice remains. The first paragraph ends with an amusing reference to "interested persons who ought to know better," as if the advocates of alternating currents worked for

the love of the thing, or for the public good, while the continuous current men alone were greedy enough to make a living out of the business. It is our duty to be impartial in this matter, and therefore, when a one-sided Paper makes its appearance, it is our business to criticise it. Had it glorified continuous currents our duty would have remained the same, but our task might have been more difficult.

The first topic naturally was pressure, and, as usual, low pressure was bracketted with continuous currents and high pressure with alternating, as though such a union were inevitable, and as though the laws of Nature forbade a continuous current of 5,000 or 10,000 volts. In fact, alternate currents effect a saving of copper—a fine old time-honoured delusion! Having assumed for a moment that such a thing as a dynamotor or continuous-current transformer was possible, he crushed it at once by "troubles arising from commutators and brushes," as though these were quite sufficient to settle the matter. It would be stepping perhaps beyond our impartial position if we accepted Dr. FLEMING's calculation of the one mile feeder, for we should then be compelled to admit that the City of London supply from Bankside could be better done with continuous currents. That the private lighting would have been more satisfactory than has hitherto been the case admits of little doubt; but that is another matter, for all such criticism is disarmed by the incomplete state of the plant. But, taking the lighting of the City, it is really a pity that no information whatever has been published by which a comparison of the first cost and working expenses of transformer sub-stations and dynamotor sub-stations may be made. Neither in Mr. PARKER's Paper nor in his remarks on Prof. THOMPSON's Paper was there a word about this, and if such information cannot be obtained from Oxford, where shall it be sought? From Chelsea, of course, no useful information can be expected.

It is no light matter, says Prof. THOMPSON, that while in a continuous current supply there is but one way of moderating or regulating the current, two modes are possible if the supply be with alternating currents. This is all very well in a lecture-room, but is it not a fact that in practice a long distance transmission where power is valuable, and must be carefully regulated and distributed, a continuous current is the only practicable method; but where there is plenty of power, and the surplus can run to waste, and especially where a single generator drives a single motor, polyphase or other alternators can be employed? A solitary disadvantage or two crept into the Paper by accident. It was admitted, of course, that the ohmic drop of volts in wiring is unavoidable; but the two other drops, that due to induction of the mains and that due to transformers, are felt only by users of alternate currents. The former of these may be reduced by the use of concentric mains, with their by no means simple joints, and the latter by the use of large and expensive transformers; both of which must be set off against the saving of copper, which is the main advantage of high pressures. The difficulties of synchronous motors were alluded to, and the intricate way out of these difficulties—by two-phase and three-phase currents—was pointed out. The unfortunate lag of phase due to inductive drop was admitted, and the lecture-room remedy—namely, condensers—was suggested; but not a word about how such currents or how the power is to be measured. So truly ingenious are these alternate current men, and so impressed are they of the infallibity of their system, that they seem rather to exult in these impediments, and at all events keenly delight in the invention of means to surmount them. The poor continuous current man has not had the opportunity of enjoying a single important improvement—except, perhaps, the Sayers winding—for several years, so lamentably simple, so faultily faultless is his plant, so childishly artless are his ways. A rather long account of the complicated system of adjusting the excitation of a motor was given, and the last paragraph but one actually contemplated the erection at one or possibly more points of the network, as remote as possible from the generating station, of synchronous motors over-excited to act as condensers in compensating the inductive drop; or, in the primary circuit also, to furnish the idle currents for magnetising the transformer primaries! How do alternate current men like this? The opinion has been expressed that "it goes without saying that it was an important addition to our knowledge on the subject, and it is to be hoped that the matter may be brought before the Institution of Electrical Engineers for adequate discussion;" perhaps the alternate current men are saying "save us from our friend!"

The climax of this Paper is brief and clear. "With such possibilities"—why not call them interesting complications?—"open in the future for alternate current working, and with such advantages"—such advantages!—"in respect of motive power, over continuous current working, it can hardly be doubted"—by a man who keeps his eyes shut—"that, save in a few special cases, the vast majority of central stations will henceforth be operated by alternate currents." We should be very reluctant to harshly criticise the carefully-thought expressions of a man of zeal, of conviction, and of purpose; but we have Prof. THOMPSON's own statement that this Paper was only a bit of special pleading; and, even if we had used severe language, it would fall as harmlessly as the fierce words which counsel hurl at each other in the law courts. Prof. THOMPSON is no manufacturer committed to bolster up a lot of expensive patents, he is no inventor of motors, transformers, or other apparatus, and bound to prove that they are indispensable to his system, and that his system is the only practicable one. Such individuals are often thin-skinned, and it is cruel, if not dangerous, to belittle their fads. It is difficult, when such a Paper is brought so prominently before the public, to maintain a strictly impartial position. Some eighteen months ago Dr. FLEMING proved as well as figures could prove, and as yet without refutation, that taking the all-day efficiency of a three-wire feeder one mile long, and delivering 24 kilowatts at 200 volts, and the all-day efficiency of a 24 kilowatt transformer and losses in a double 7/16 primary cable one mile long, that there was practically nothing to choose between the total annual costs. But we then observed that there was still plenty of room for alternating currents under certain circumstances, and that we thought that Dr. FLEMING had rather overdone his comparison, and we were loth to believe that the result was so greatly in favour of continuous currents as his calculations showed. Since then transformer efficiencies have improved, and since then also a five-wire system has been successfully worked. Prof. THOMPSON's Paper suggests that choking coils, condensers, over-excited motors and polyphase currents may be required, to say nothing of more or less automatic complex sub-station switching gear and station synchronising apparatus, to which he made no allusion. The continuous current system needs none of these, and will therefore hold its own, nor can it be excluded from the alternate current stations themselves, for attention must even there be paid to the greatly dreaded commutators and the mischievous brushes.

But we are thoroughly impartial, and are convinced that a majority, and perhaps a considerable majority, of *future* stations will generate alternate currents, for the simple reason that Manchester, Liverpool, Birmingham, Glasgow, and Edinburgh, and other important cities and towns, are

Digitized by Google

committed to the continuous current system, which has proved so successful in London. In London, at the beginning of this year, there were about 373,000 lamps supplied by continuous currents, and about 320,000 by transformers. This is no test of merit, nor would the dividends, though exhibiting a striking difference in favour of the former, give a basis for comparison. The fact is that the continuous-current men seized on the cream of the districts, and the alternate current men had to put up with what other parts they could find. In the provinces there were 235,000 lamps on continuous currents and 181,000 on alternating current mains; and this, largely for the same reason, but not altogether; for the five largest cities were well advised in adopting the system which is so admirably suited for densely-populated districts.

There remain, as we said in our opening paraphrase of Prof. THOMPSON's words, certain disadvantageous circumstances under which alternate currents will prosper, and this is their glory. There is much barren soil which no continuous current man cares to till, but from which an alternating man may with care reap a golden harvest. It is greatly to be hoped that the dynamos which he will use will be constructed on sound principles of mechanical engineering, the engines connected direct, the transformers free from annoying drop of volts, the station switching gear decently simple, not spread all over the station, and not blinking the lights all over the district whenever it is handled. These engineering difficulties are not insurmountable, and the scientific difficulties for which such ingenious remedies are proposed will, we believe, disappear of their own accord. They are merely kept before us by scientific men who enjoy them. When HERTZ visited this country in 1890 he was asked some question about alternate current transformers. He had never heard of them, and had no idea of their use. Happy man!

WOODHOUSE AND RAWSON.

From June 18th until a few days ago Mr. Registrar HOOD, aided by the Official Receiver, Mr. C. J. STEWART, and a cohort of Counsel, was intermittently engaged in inquiring into the affairs of Woodhouse and Rawson United (Limited), with the result that no one seems to have been found guilty of anything. To the unsophisticated this may possibly appear to be an extremely tame ending to an extremely lame story. It must, however, be borne in mind that it is not so much formal punishment as mere inconvenience and fear of publicity that deter, and the Board of Directors which could face with equanimity the publicity, physical inconvenience, mental strain, and loss of time, money and dignity inherent to such an inquiry as that recently terminated, would probably go further and fare worse—at Old Bailey. To ordinary men—that is to say, to most directors—considerations such as those just mentioned are, by themselves, likely to prove wholesome and powerful deterrents. When inquiries under the Companies Act of 1890 have been multiplied sufficiently, promoters and directors of companies, it is permissible to anticipate, will have been educated up to their legal and moral responsibilities, and the public, it is to be hoped, will have learnt the unwisdom of confiding the management of commercial and manufacturing undertakings to inadequately salaried men without special business training, and of placing any reliance whatsoever upon auditors' certificates as they are now drawn up. In another column we reproduce an article on the promotion and management of limited liability concerns, by Mr. GEORGE WREFORD, every line of which, with unimportant exceptions, we endorse. Mr. WREFORD proposes, amongst other things, to increase the power of the Board of Trade to such an extent as to make the Certificates of Incorporation, which are at present—like so much connected with the law of joint-stock companies—completely misleading, a kind of Government guarantee of the *bona fides* of the concerns to which certificates are issued. Such a plan, it seems to us, is objectionable on two grounds. No Government department, no, not even the Board of Trade, could really make sure of the good faith of company mongers, so that the guarantee would be illusory and lead to worse than has hitherto befallen the investor. Secondly, such a guarantee would tend to make the average investor even more inclined to trust in the integrity and ability of others than he already is. Let the duties and responsibilities of promoters, directors, and auditors be accurately defined, and the punishment for derelictions of trust be made certain and speedy, and the law will have done all it can safely do to protect the unwary investor. Even this degree of protection is deemed by some excessive, and likely to prove detrimental to trade; as if the commercial reputation of the nation could by any possibility be enhanced and its investors encouraged by such a tale as that just told to Mr. Registrar HOOD.

In August, 1889, Woodhouse and Rawson United (Limited) invited the public to supply it with capital, and by May, 1893, it was being wound up, having between times successively floated a number of not over-successful companies, paid a couple of huge dividends, and declared a balance loss of £130,000. Without questioning the original solvency of the constituent items of this concern, or the correctness of the valuation of the patents and good-will at £85,500 and £97,000 respectively, we will only point out that had two small things been done, which undoubtedly ought to have been done, Woodhouse and Rawson United would, in all probability, never have secured any money from the public, and the electrical industry would have been spared association with such a disastrous venture. Had it been made indubitably clear to the public that what they were asked to subscribe to was to be largely a limited liability financing concern, it may well be doubted whether they would have risen to the bait offered. That this point was not made indubitably clear is evident from the Registrar's own researches. He found that the clause in the Memorandum of Association which was brought forward as exonerating everyone from intentionally misleading the uninitiated was common to 70 out of 93 Memoranda examined by him. Again, had the circular which was sent round to the applicants upon the retirement of the three directors who were dissatisfied with the amount of capital subscribed, contained, as promised to them, the statement that any money subscribed could be had back, the rise and fall of Woodhouse and Rawson United would not, we venture to think, have occurred. Lastly, without endeavouring to do that which has partially defied the skill even of the OFFICIAL RECEIVER, namely, to unravel the tangled skein of the affairs of Woodhouse and Rawson United, the Woodhouse and Rawson Electric Supply Company, the Woodhouse and Rawson Manufacturing Company, the Woodhouse and Rawson Contract and Maintenance Company, and C. L. Baker and Co., the main cause of the disasters that befell the concern which united these threads of varied hue into a garment of so many colours was the ambitious and unskillful attempt to combine *la haute finance* with a plain, everyday manufacturing business. Remembering 1883, one would have thought that a second object lesson in the danger attending such an enterprise would scarcely have been needed.

REVIEWS.

Traité de Télégraphie Électrique. By H. Thomas. (Paris: Baudry et Cie.)

Division of labour is no doubt an admirable device for obtaining the best, or rather we should say the maximum, effect for a given consumption of mental or physical energy. But whilst the happiest results usually accrue from one set of men sitting down to chronicle the deeds of another set, it is difficult to realise why a nation which is admittedly at the head of the telegraphic branch of engineering should leave the writing of the two best text-books on the subject in the hands of foreigners; for in Wünschendorff's "Traité de Télégraphie Sous-Marine," reviewed in these columns some years since, and in Thomas's "Traité de Télégraphie Électrique," now under consideration, we have the best treatise hitherto published on submarine and land-line telegraphy respectively. The reason for this strange phenomenon is probably to be sought for in that highly developed critical faculty and that power of lucid expression which enable French writers, even on such subjects as practical telegraphy, first to winnow the wheat from the chaff, and then to compound the residue into an attractive whole. We probably possess a copious supply of telegraph men with practical knowledge enough, especially in so far as submarine telegraphy is concerned, to put the authors of these two treatises to immediate flight. But it is permissible to doubt whether, all official restrictions being removed, they would turn out as satisfactory a compilation as either that of M. Wünschendorff or that of M. Thomas. We probably should be unable to see the forest for the trees.

In his "Traité de Télégraphie Électrique," M. Thomas has succeeded in rendering what may be termed the philosophy of telegraphy positively palatable. No only so, but the typography and the illustrations of his volume are also excellent; readers are not treated to an irritating succession of old outside views of ancient apparatus, but the meaning of the letterpress is elucidated both by well-drawn sectional views of actual modern mechanisms and by helpful diagrammatic sketches; the mathematical digressions, which are few and far between, are neither awkwardly thrown into the middle of the descriptive matter, nor relegated to the end of the volume, but are placed in their proper place, but in small type. In addition to other favours, the author has seen to it that what he has compiled does not remain unread or unreferred to for lack of a table of contents and a good index.

One of the best and briefest chapters in the whole volume is that devoted to the question of the propagation of an electric current along a telegraph line, in which the general principles governing the adaptation of instruments to circuits having capacity and inductance are illustrated by useful curves. Relays and line dischargers are discoursed upon in Chapter XI.; the scientifically interesting device of d'Arlincourt, with its so-called *coup-de-fouet* action, having several pages devoted to it. The chapters on printing, writing, automatic, diplex, duplex, quadruplex, multiplex and harmonic telegraphs, although long, are excellent of their kind, and exhibit a sense of proportion not too often met with, but which characterises the author's work throughout.

Alternating Currents. By Frederick Bedell, Ph.D., and A. C. Crehore, Ph.D. (New York: The W. J. Johnson Company. London: Whittaker and Co.) Second edition. 1893.

In this second edition the authors have not thought it necessary to make any material changes "either in the subject-matter or in the arrangement" of their book. We cannot but regret that this is the case, and our criticisms of the first edition (*The Electrician*, Vol. XXXI., p. 124) must apply to the book as it now stands, in its latest form. There is still the same airy show of mathematics, without the necessary appeal to the evidences of actual experiment. There is still the same apparent desire on the part of the authors to wander away along the paths of abstract mathematical analysis, to investigate, for example, "the criterion of integrability" of a given set of conditions by appeal to Laplacians, where a simple mental inspection of the conditions would show just as much as the complicated mathematics can do. We confess to the uneasy suspicion, in reading this book, that wherever the authors have had a choice between a simple, obvious treatment and a complicated, round-about one, they have invariably cast in their lot with the latter. Students and engineers, to whom the work is addressed, do not, as a rule, care to thread their way through a maze of formulæ when the result to be attained can be arrived at by a more direct and simpler route.

We notice that the authors still make the curious statement that the inequality of consumption of the two carbons, in an alternating-current arc lamp, may be explained by the shape of the curve of positive current differing from that of the curve of negative current.

Mathematicians in search of a discussion on and expansion of one or two equations, which happen to be expressions for alternate-current phenomena, may find an interest in this work; but, as an engineering or technical treatise, it can have little value.

The Practical Management of Dynamos and Motors. By F. B. Crocker and S. S. Wheeler, D.Sc. (New York: D. Van Nostrand Company. London: E. and F. N. Spon.) Second edition. 1894.

The present volume consists of a revision and enlargement of the series of articles originally published in the *Electrical Engineer*, of New York, and which first appeared in book form in 1892. The arrangement of the matter in this present edition is similar to that adopted from the first, and is calculated to be of assistance to the reader who is desirous of turning up information about any particular piece of dynamo practice. An entirely new part has been added on the management of arc lighting machinery; and the section on inspection and testing of dynamos has been amplified and is placed in a separate part. If some of the faults stated to occur in dynamo machinery appear somewhat improbable, this can only be due to the evident desire of the authors to omit no possible accident from the category dealt with in their book. For every accident the authors suggest one, or sometimes more than one, remedy; and, with such a book as this within reach and a fair amount of common sense, no dynamo attendant should find himself in an inextricable difficulty. The book makes a useful *vade mecum* for dynamo attendants, and is of a convenient size and shape for the purpose.

ON MAGNETISATION PRODUCED BY HERTZIAN CURRENTS—A MAGNETIC DIELECTRIC.*

BY M. BIRKELAND.

"Two years ago† it was proved by conclusive experiments that Hertzian waves travelling along an iron wire magnetise transversely the very thin layer into which the alternating current penetrates, and whose thickness does not exceed some thousandths of a millimetre. Once proved that alternate magnetisation can be produced with such rapidity, other questions present themselves. One asks, for instance, if it is not possible to demonstrate in magnetic cylinders stationary magnetic waves analogous to the electric stationary waves along metallic wires."

The author finds that the conductivity of massive iron makes it an unsuitable substance, and uses instead a mixture of iron filings, or of chemically-obtained iron powder, with paraffin, to which he sometimes adds powdered quartz. This he moulds into cylinders, and inserts as the core of a spiral in an otherwise ordinary Hertz resonator.

The figure shows emitter and receiver drawn to scale; the magnetic cores are introduced into the spiral A, and their effect on the length of the resonator spark is observed. With this arrangement of exciter the *electric* effect of the spiral is negli-

* Abstracted from *Comptes Rendus*, June 11, 1894, and communicated by Dr. Oliver Lodge.

† Why two years ago? It was practically proved by Savart early in the century, and has been observed over and over again since. However, it is true that experiments have been more numerous and conclusive of late, and have been pushed to very high frequencies.—O. J. L.

Digitized by Google

gible, since it is well removed from electrostatic disturbance, and subject only to magnetic. The spiral is of twelve well-insulated turns, the spark-gap is a micrometer with point and knob, and a pair of adjustable plates to vary the capacity for purposes of tuning.

He employed twelve different types of cylinder, all about 20cm. long, and 4cm. diameter.

1. A massive cyclinder of soft iron.

2. A bundle of fine iron wires embedded in paraffin.

3—9. Six cylinders of the agglomerate of chemically-reduced iron in powder and paraffin, containing respectively 5, 10, 15, 20, 25, and 50 per cent. of iron.

Then for control experiments:—

10. A cylinder of agglomerate of zinc powder in paraffin, with 40 per cent. of zinc.

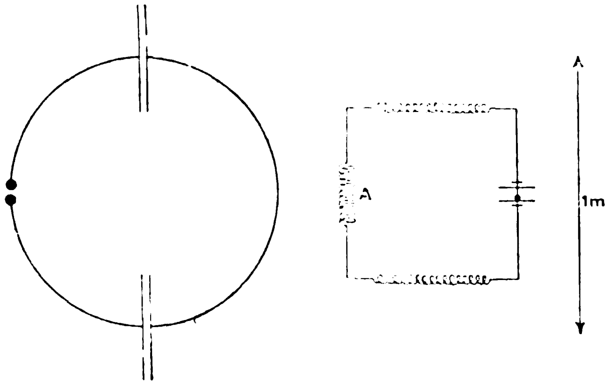
11. A cylinder of brass filings in paraffin, 20 per cent. of metal.

12. A tube of glass, 4·5cm. diameter, filled with various electrolytes.

The manner of observing was as follows (the experiments were done in the laboratory of Hertz):—

The resonator, with its spiral empty, was syntonised with the exciter, and the maximum spark measured. It was between 4 and 9mm. long in these experiments. Then one or other of the above cylinders was introduced and the spark-length measured afresh.

Cylinder 1 did not affect the maximum spark-length. Cylinders 2—4 reduced the maximum spark to $\frac{1}{10}$th of its



former value: 7 and 8 to $\frac{1}{100}$th, and No. 9 to $\frac{1}{200}$th of its former value (viz., from 9mm. to 0·05mm.). Nos. 10 and 11 had but a feeble action, they reduced the spark from 8mm. to 7mm.

Tube No. 12, filled with distilled water, scarcely affected the spark length; the period of the secondary increases a little, but the maximum spark is the same as before, once syntony is re-established. Filled, however, with dilute sulphuric acid containing 10, 20, or 30 per cent., the tube reduced the spark considerably, in each case about the same, viz., from 9 to 1·3 about. (Currents induced by Maxwellian radiation in electrolytes had been already observed by J. J. Thomson.)

While trying to re-establish syntony between primary and secondary, I found that the period of the resonator was considerably increased by the cylinders 2—4, but that the maximum spark length was much diminished. With the cylinders Nos. 5—9 in the spiral, it was no longer possible to establish syntony, "a fact which is certainly due to their considerable absorption of energy. Take, for example, cylinder 9: electromagnetic energy must converge rapidly towards it in order to be transformed, and the space finds itself empty of energy as air is exhausted of vapour in presence of an absorbing substance.

"This absorption is probably due to hysteresis in the ferruginous cylinders; the development of Joulian heat, so typically shown by cylinder 12, being undoubtedly of the same order in cylinders 3—9 as in Nos. 10, 11.

"It is probably by reason of this absorption that I have not succeeded in establishing stationary magnetic waves in a circuit of ferro-paraffin."

If one of the cylinders, 2—9, is wrapped in tinned paper before introducing it into the spiral A, its action is completely stopped. (These conducting cores *diminish* the period of the resonator; it is much as if the spiral A were partially shunted out; but the maximum spark returns as soon as syntony is re-established.) To examine this further he enclosed the cylinder in drums of cardboard having fine wires either along generating lines, or along circular parallels. The latter suspended the action of an interior ferruginous cylinder, the former did not.

To find to what depths the magnetism penetrated, Birkeland inserted hollow ferruginous drums into A, measured their effect, and then plunged solid cylinders into them to see whether the effect increased.

He thus found that the magnetisation easily traversed 7 millimetres thickness of the 10 per cent. ferro-paraffin, and 5 millimetres of the 25 per cent.

The substance is comparable to a dielectric on the theory of Poisson-Mossotti.

"The results obtained with our magnetic dielectric invite to new researches"—such as the mechanical force excited by electric waves on a delicately-suspended ferro-paraffin needle, and the rate of propagation of Maxwellian waves through such a substance.

PRELIMINARY EXPERIMENTS TO FIND IF SUBTRACTION OF WATER FROM AIR ELECTRIFIES IT.*

BY LORD KELVIN, P.R.S., MAGNUS MACLEAN, M.A., F.R.S.E., AND ALEXANDER GALT, B SC., F.R.S.E.

Experiments with this object were commenced by one of us in December, 1868, but before any decisive result had been obtained, circumstances rendered a postponement of the investigation necessary.

A glass U-tube with vertical branches, each 18in. long and about 1in. bore, with the upper 8 inches of one of the branches carefully coated outside and inside with clean shellac varnish, was held fixed by an uninsulated support attached to the upper end of this branch. The other branch was filled with little fragments of pumice soaked in strong pure sulphuric acid or in pure water; and a fine platinum wire, with one end touching the pumice, connected it to the insulated electrode of a quadrant electrometer. A metal cylinder, large enough to surround both branches of the U-tube without touching either, was placed so as to guard the tube from electric influences of surrounding bodies (of which the most disturbing is liable to be the woollen cloth sleeves of the experimenters or observers moving in the neighbourhood). This metal tube was kept in metallic connection with the outside metal case of the quadrant electrometer. The length of the exposed platinum wire between the U-tube and the electrometer was so short that it did not need a metal screen to guard it against irregular influences. An india-rubber tube (metal metallically connected with the guard cylinder would have been better) from an ordinary blowpipe bellows was connected to the uninsulated end of the U-tube. Air was blown through it steadily for nearly an hour. With the sulphuric pumice in the other branch the electrometer rose in the course of three-quarters of an hour to about nine volts positive. When the pumice was moistened with water, instead of sulphuric acid, no such effect was observed. The result of the first experiment proves decisively that the passage of the air through the U-tube gave positive electricity to the sulphuric acid, and therefore sent away the dried air with negative electricity. A corresponding experiment with fragments of chloride of calcium, instead of sulphuric pumice, gave a similar result. In repetition of the experiments, however, it has been noticed that the strong positive electrification of the U-tube seemed to commence somewhat suddenly when a gurgling sound—due to the bubbling of air through free liquid, whether sulphuric acid or chloride of calcium solution, in the bend of the U-tube—began to be heard. We intend to repeat the experiments with arrangements to prevent any bubbling of the air through liquid.

We have repeated our original experiment with pumice moistened with water in the insulated U-tube, and with an uninsulated U-tube filled with sulphuric pumice between the bellows and the insulated tube, so that the air entering it is

* Paper read before Section A of the British Association, at Oxford.

artificially dried. With this arrangement the insulated U-tube was negatively electrified by the blowing of the air through it; but this electrification may have been due to the negative electrification of the dry entering air, to be expected from the result of our first experiment. We intend to repeat the experiment with artificially dried *and dis-electrified* air blown through the U-tube containing pumice moistened with water.

PRELIMINARY EXPERIMENTS FOR COMPARING THE DISCHARGE OF A LEYDEN JAR THROUGH DIFFERENT BRANCHES OF A DIVIDED CHANNEL.*

BY LORD KELVIN, P.R.S., AND ALEX. GALT, B.SC., F.R.S.E.

In these experiments the metallic part of the discharge channel was divided between two lines of conducting metal, each consisting in part of a test-wire, the other parts of the two lines being wires of different shape, material, and neighbourhood, of which the qualities in respect to facility of discharge through them are to be compared.

The two test-wires were, as nearly as we have been hitherto able to get them, equal and similar, and similarly mounted. Each test-wire was 51cm. of platinum wire of 0·006cm. diameter and 12 ohms resistance, stretched straight between two metal terminals at the ends of a glass tube. One end of the platinum wire was soldered to a stiff solid brass mounting; the other was fixed to a fine spring carrying a light arm for multiplying the motion. The testing effect was the heat developed in the test-wire by the discharge, as shown by its elongation, the amount of which was judged from a curve traced, by the end of the multiplying arm, on sooted paper carried by a moving cylinder. Two of Lord Kelvin's vertical electrostatic voltmeters, suitable respectively for voltages of about 10,000 and 1,500, were kept constantly with their cases connected with the outer coatings of the leyden, and their insulated plates with the inside coatings of the leyden.

I. In the experiments hitherto made the two wires to be tested have generally been of the same length. When they were of the same material, but of different diameters, the testing elongation showed, as was to be expected, that the test-wire in the branch containing the thicker wire was more heated than the test-wire in the other branch. In a continuation of the experiments we hope to compare hollow and tubular wires of the same external diameter, and same length and same material.

II. With wires of different non-magnetic material—for example, copper and platinoid—of the same length, but of very different diameters, so as to have the same resistances, the testing elongations were very nearly equal.

III. In one series of experiments the tested conductors were two bare copper wires, each 0·16cm. diameter, 9 metres long, and resistance 0·085 ohm, which, it will be observed, is very small in comparison with the 12 ohms in each of the platinum test-wires. One of the copper wires, was coiled in a uniform helix of 40 turns on a glass tube of 7cm. diameter. The length of the helix was 35cm., and the distance from centre to centre of neighbouring turns therefore $\frac{7}{8}$cm. The middle of the other copper wire was hung by silk thread from the ceiling, and the two halves passed down through the air to the points of junction in the circuit. The elongation of the test-wire in this channel was more than twice as much as that of the test-wire in the channel, of which the helix was part.

IV. One hundred and seventy-one varnished pieces of straight soft iron wire were placed within the glass tube, which was as many as it could take. This made the testing elongation 10 times as great in the other channel.

V. The last comparison which we have made has been between iron wire and platinoid wire conductors. The length of each was 502·5cm. The diameter of the iron wire was 0·034cm., and its resistance 6·83 ohms. The diameter of the platinoid wire was 0·58cm., and its resistance 6·82 ohms. Each of these wires was supported by a silk thread from the ceiling, attached to its middle (as in III. and IV. for one of the tested conductors). Fourteen experiments were made, seven with the test-wires interchanged relatively to the branches in which they were placed for the first seven. The following table shows the means of the results thus obtained, with details regarding the electrostatic capacities of the leyden-jars and the voltages concerned in the results.

In each case four leyden-jars, connected to make virtually one of capacity of 0·02742 microfarad, were charged up to 9,000 volts, and discharged through divided channel. The energy, therefore, in the leyden before discharge was 11·105 $\times 10^6$ ergs. In each of the first three cases 1,450 volts were found remaining in the jars after discharge; in each of the last four 1,400.

Energy remaining in leyden after discharge.	Energy used.	Elongation of testing wires in cms.			
		In channel containing platinoid.	Means.	In channel containing iron.	Means.
$0·29 \times 10^6$ ergs	$10·82 \times 10^6$ ergs	0·01794	0·01829	0·01226	0·01239
"	"	0·01861		0·01247	
"	"	0·01832		0·01244	
$0·27 \times 10^6$ ergs	$10·84 \times 10^6$ ergs	0·01823	0·01836	0·01276	0·01261
"	"	0·01828		0·01280	
"	"	0·01828		0·01244	
"	"	0·01865		0·01244	

The mode of measuring the elongation of the test-wires was, as may be understood from the preceding description, somewhat crude; but it is reassuring to see that the mean results in the cases of 10·82 and 10·84 megalergs of energy used are so nearly equal. The ratios for the two circuits are, in the two cases, respectively 1·48 and 1·46. The conclusion that the heating effect in the test-wire in series with the platinoid wire is nearly one and a half times as great as that of the test-wire in series with the iron is certainly interesting, not only in itself, but in relation to Prof. Oliver Lodge's exceedingly interesting and instructive experiments on alternative paths for the discharge of leyden-jars, described in his book on "Lightning Conductors and Lightning Guards," which were not decisive in showing any general superiority of copper over iron of the same steady ohmic resistance, but even showed in some cases a seeming superiority of the iron for efficiency in the discharge of a leyden-jar. Our result is quite such as might have been expected from experiments made eight years ago by Lord Rayleigh and described in his Paper "On the Self-Induction and Resistance of Compound Conductors."*

RESISTANCE AND TEMPERATURE COEFFICIENT OF COPPER-ZINC ALLOYS.

The specific resistances of a series of 18 wires of copper-zinc alloys form the subject of a Paper by Herr Robert Haas, in No. 8 of *Wiedemann's Annalen*. The number of alloys prepared was 28, but it was found impossible to draw them into wires when the percentage of zinc exceeded 47. The object of the investigation was the discovery of any possible "singular points" in the curves showing the relation between the composition of the alloys and their conductivities and temperature coefficients. Such a point was actually found when the percentage of zinc was 34, or that corresponding to the formula Cu_2Zn.

The greatest precautions were taken to ensure the perfect purity of the materials used. The copper was covered with powdered and dried borax during fusion in the crucible, and the zinc was added in pieces of half a gram at a time. Every such addition was attended with a slight explosion, probably a spheroidal phenomenon. The ingots were cast in the form of bars 4mm. thick, and then wire-drawn.

The electrical measurements were carried out by the metre-bridge, the standard resistance being a German-silver wire, and the specimen being heated in an oil bath. The percentages of the constituents were subsequently determined by electrolysis.

In every case the specific resistance was found to be a linear function of the temperature. The alloys resemble the pure metals in this respect, except iron. The specific resistance of pure copper was found to vary from 0·0158 to 0·0159. Matthiessen's classical value was 0·0156 for hard and 0·0154 for soft copper. The close approximation is ascribed by the author to the use of the borax and of a gas furnace. The table shows that the specific resistance of the alloy increases rapidly at first with the percentage of zinc. After about 5 per cent. it becomes slower, culminating at 34 per

Digitized by Google

cent., at which point the resistance exceeds that of pure zinc. At 47 per cent. the specific resistance was the same as at 14 per cent. The temperature co-efficient rapidly diminishes as the percentage of zinc increases from 0 to 7. Between 17 and 30 the curve is nearly horizontal. After a minimum about 34 it increases again, and at 47 it is the same as at 2 per cent.

The following table contains some of the results of the measurements:—

Percentage of zinc.	Specific resistance in ohms.	Temperature coefficient.
0	0·01592	0·004328
1·56	0·02133	0·003185
5·51	0·03010	0·002383
18·02	0·04763	0·001691
22·71	0·05424	0·001607
34·23	0·06302	0·001579
42·55	0·05307	0·002376
46·85	0·04314	0·003105
100	0·05683	0·004029

In conclusion, the author points out that the results indicate a chemical alloy represented by Cu_2Zn. Whether the other alloy, of the formula $CuZn_2$, suspected by A. P. Laurie, also exists, could best be found by means of the induction balance, which does not necessitate the alloys being wire-drawn.

THE LIVERPOOL OVERHEAD RAILWAY.*

BY JAMES HENRY GREATHEAD AND FRANCIS FOX, MM. INST. C.E.

The need for better conveyance for passengers along the line of docks at Liverpool, a length of about 6½ miles on the eastern shore of the river Mersey, has long been felt. As far back as 1852, a proposal was made by Mr. John Grantham for a high-level railway from the Mersey Forge to the Huskisson Dock, a distance of four miles. His plan was to have six lines of way carried on columns 20ft. in height, the space below being utilised as warehouses; but whether from its magnitude or from some other cause, nothing came of the proposal.

The elevated railways over some of the streets in New York have proved of great public convenience. In 1866 a proposal was brought forward for the construction of an "overhead," or as it is now better known, an "elevated" railway in that city, and in 1872, the necessary charter having been obtained, the first elevated railway there was constructed. Although not at once successful, this railway was the forerunner of the present elaborate system of similar railways in New York. Owing to the length and narrowness of the city, no less than four such railways have been constructed, running in generally parallel lines from north to south, within a width of about one mile. The total length is about 35 miles, including about four miles of suburban railway recently completed, the capital embarked is about £10,000,000, and the number of passengers conveyed last year reached the enormous total of 221,000,000, producing a gross revenue of £2,315,000, at a cost of £1,152,000 for working. The Third Avenue line alone, about 8 miles long, carried no less than 83,500,000 passengers, or at the rate of nearly 10,500,000 per mile in the year. Though of great service to the travelling public, these railways have, on the other hand, been attended by several inconveniences; they have no parapets, and the sleepers or cross ties are placed directly on the top flanges of the girders without the intervention of a floor of any description. The result is that as the railways are worked by steam-locomotives, cinders, oil and water drop into the streets; fine shavings from the rails and tyres of the wheels fall on to foot-passengers, in some cases resulting in personal injury, and on one occasion, at least, a locomotive has fallen bodily into the street.

The authors are indebted to Mr. George Fosbery Lyster, M. Inst. C.E., Chief Engineer of the Mersey Docks and Harbour Board, for the following reference to the history of the Liverpool undertaking. About 15 years ago it became apparent that the low-level lines of railway which traversed the whole length of the dock-estate, having connections with the different goods stations along its margin, were becoming so overcrowded by the dock traffic as shortly to render it impossible, consistently with the public convenience, to allow the omnibuses which had been permitted by the Dock Board under special restrictions to continue to use those lines. For that reason, combined with the over-crowding of the adjoining streets, it was clear that some other means must be provided for the expeditious transit of the public. The surface being fully occupied, it will be readily seen that the improved facilities would have to be obtained by the construction of a new line of communication either under or above the surface. A tunnel line was considered, but was speedily abandoned as being too costly, too difficult to construct, and open to other objections in that situation. An overhead structure was therefore considered to be the only practical solution of the difficulty, and in order to obtain full and exact information as to what had hitherto been done in this direction, Mr. A. G. Lyster proceeded to New York to study the system established there, on which he subsequently presented an exhaustive report. Various plans and sketches for such a work were then prepared in Mr. Lyster's office under his instructions and direction. Mr. Alfred Holt, M.Inst.C.E., at that time a member of the Dock Board, early arrived at the conclusion that a single line of railway with passing-places at the stations would be sufficient; and upon an instruction of the Board, at his instance, a series of plans, reports, estimates and models of such structures were prepared by Mr. Lyster, who was, however, always inclined towards a double line. When matured, this scheme was submitted to Col. Yolland and other officers of the Board of Trade, who refused to approve of it on the ground that the structure should be of a character to take two lines of the standard 4ft. 8½in. gauge.

The matter then remained in abeyance for some time, pending the preparation of surveys, designs and estimates for a double line. An Act was obtained by the Dock Board in 1882 for the construction of the railway at an estimated cost of about £585,000 (subsequently reduced to £466,000 for a system fully equipped and worked by electricity). In 1885 Mr. Lyster presented a report to the Dock Board dealing minutely with the course of the proposed line and the interference it would involve with the streets and the existing dock-lines, the stations (of which there were to be 23), the equipment and the working. It was proposed that the width of the structure should be such as to admit of a double line of standard gauge with 4ft. between the lines; the carriages to be 6ft. 6in. wide, assimilated to those in use on street tramways, but longer and therefore of greater capacity. It is interesting to record that at that time electric traction had so far advanced as to be favourably considered by Mr. Lyster for propelling the trains, which were estimated to weigh when loaded 24 tons each, exclusive of motive power, and that he was in communication upon this subject with the late Sir William Siemens at the time. The structure was intended to consist of plate girders, with overhanging continuous foot-ways having parapets of iron lattice-work, with the rails laid upon greenheart planking; the whole being supported by columns of partial lattice-work placed in the normal structure, one on each side of one of the lines of dock railway.

Owing to the fact that many influential members of the Dock Board were unwilling to embark upon the railway undertaking, as being outside the scope of their functions as representatives of the dock estate, the Board in 1887 applied to Parliament for power to lease the undertaking to an independent company. As it was required that the lessees should be a statutory company the present Overhead Railway Company was incorporated by an Act in the following year, with power to undertake, by agreement with the Dock Board, the construction and maintenance of the railway. Under the chairmanship of Sir William B. Forwood, the Company raised the necessary capital and proceeded to construct the railway as it now exists. The contract for the structure was, after competition, let to Mr. J. W. Willans, to whose untiring energy and skill is due, in no small measure, the successful execution of this important work.

In the structure decided upon by the engineers the columns are placed generally vertically under the ends of the main girders, about 22ft. apart from centre to centre, giving sufficient width above for two lines of standard gauge with the usual 6ft. way between them, admitting of the use of carriages of full width (8ft. 6in.), and below for the two lines of dock railway. Local circumstances in many cases did not, however, admit of the columns being placed immediately under the main girders; and in such cases the latter are carried upon cross-girders between the columns or upon extensions of the cross-girders outside the columns. For considerable lengths also the columns had to be embedded in the boundary and warehouse walls. Owing to the presence of the dock lines below, cross-bracing of the piers in the usual way was impossible, and it was necessary to give to the columns, and to the shallow cross bracing connecting them at the top, sufficient strength and rigidity to resist the lateral stresses due to wind-pressure, and, on the curves, to the centrifugal force resulting from the motion of the trains. In designing the details of the superstructure the engineers were aided by Mr. F. Hudleston, Assoc.M.Inst.C.E., of the contractor's staff, and Mr. G. A. Hobson, M.Inst.C.E.; the latter of whom, in connection with this work, specially designed the floor which bears his name, and which is now adopted extensively elsewhere.

The length of the railway, including the short northern extension now approaching completion, but exclusive of an authorised southern extension of about 1 mile, is about 6½ miles, the portion at present

* The first of two Papers read before the Institution of Civil Engineers, February 27, 1894; the second being "The Electrical Equipment of the Liverpool Overhead Railway," by Mr. Thomas Parker.

Digitized by Google

worked being about 5 miles. There are in all 13 stations in use, and it is intended to add four more, Fig. 1. The gradients are, generally speaking, easy; but owing to the position of the coal-line of the Lancashire and Yorkshire Railway at Wellington Dock, the overhead railway had to be carried underneath that railway, which entailed a short gradient of 1 in 40 on each side of the coal railway. The sharpest curve is of seven chains radius, and with the exception of a short length under the coal railway at the point above referred to, the railway throughout is an iron viaduct. The advantage of having a fire-proof structure in such a situation has been proved on a recent occasion, when a large fire occurred at one of the timber yards at the Canada Dock, the flames from which swept across the railway for several hours without doing serious injury except to the longitudinal sleepers, which, for a length of about 50 yards, were destroyed. Where it crosses the entrance of the Stanley Dock, a swing-bridge has been provided, both for the dock goods-lines and general traffic and for the overhead railway. At three points open bridges had to be provided to permit boilers and other high loads to pass the structure, and at these points lift or tilt-bridges have been introduced as being the simplest and most convenient type.

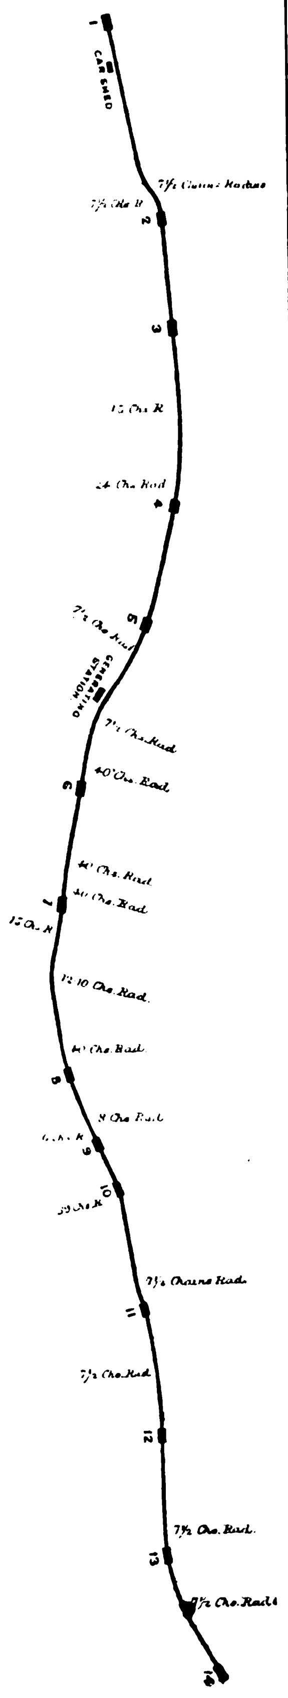

Fig. 1.—The Plan of Line.

Foundations. — No special difficulties arose in connection with the foundations of the piers. The rock is reached by them in many places, but in others, where the material excavated from the docks had been deposited and the foundations are in made ground, a block of concrete was provided to distribute the dead-weight and rolling-load in such a manner that 1 ton per square foot is the maximum load on the base. Some of these foundations were tested with pig-iron to 50 per cent. more than the greatest working-load, with satisfactory results in all cases. Along the Goreea deep sewer was encountered, running parallel with the railway and directly under one line of columns. An arch of cement concrete was built over the sewer and the columns were fixed upon that.

Alterations to the Dock Board's Goods Lines.—Owing to the railway being placed immediately over the dock-lines, the latter were in many instances diverted, straightened and improved, thus entailing considerable expense upon the Company. Police - stations, customs-depots, and other erections in the course of the line, had to be removed and re-erected elsewhere. It may be interesting to record that, in excavating for the foundations, the wall of the first dock made in Liverpool was discovered. Several lengths of the old water-pipes, consisting of trunks of trees bored out and fitted together were brought to light.

Columns.—The columns supporting the viaduct consist of two steel channel-bars riveted to two steel plates, forming a box-column with all the rivet-heads outside. These columns are grouted into cast-iron sockets, bedded in and bolted through the blocks of concrete which form the foundations. Cast-iron bumpers filled with cement concrete, protect the columns against injury from passing wagons (Fig. 2). The normal span is 50ft., but this had to be departed from in many places to avoid interference with existing lines, roads, gateways, and other structures. The longer spans are about 98ft., and the shorter about 30ft. Up to 75ft. span, the height of the girders above the rail-level does not exceed the platform-height, and plate-girders were used. Bowstring lattice-girders were used for the 98-foot spans, with a clear width of 25ft. between them. The plate-girders carry a light projecting parapet composed of gas-tubing and wrought-iron stanchions with curved foot-plates, affording a continuous foot-way on each side of the line, with wider refuges at the piers. The girders are not continuous, and provision is made by slotted holes for expansion and contraction at one end of each girder.

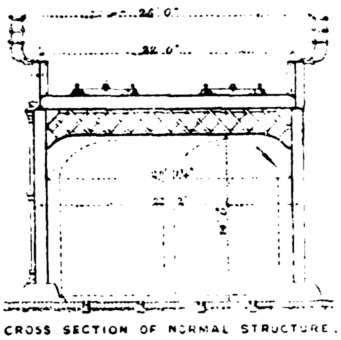

Fig. 2.

Between the girders is fixed Hobson arched-plate flooring, consisting of $\frac{5}{16}$in. plates, bent to a radius of 12in., with a flat surface 6in. wide on the top, rivetted to intervening T-irons, and made water-tight by asphalte placed in the V-channels between the arches (Fig. 3). Upon this are laid longitudinal creosoted sleepers keyed to the flooring, and no ballast is used. From each V-channel an outlet for water is provided through the web of one of the main girders, discharging into a light cast-iron gutter carried along the outside of the main girder, which conveys the water to a rectangular down-pipe fixed to the columns delivering into the drains or gutters below. This flooring combines great strength with lightness and a minimum of rivetting, while the load is more evenly distributed along the main girders than is the case where cross-girders are employed, and great lateral stiffness is secured without horizontal bracing. The flooring is practically water-tight, and after 12 months' test under traffic has not shown any defects. In order to ascertain the strength of the floor, some sections were

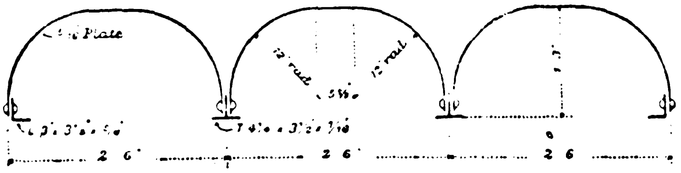

Fig. 3.

tested to destruction and the deflections at each increase of load carefully tabulated with the following results :—

Test.—Three sections of floor measuring 7ft. 6in. in width; span, 22ft., ends resting upon supports; load distributed over four points corresponding with the positions of the rails, Fig. 4.

Load. Tons.	Deflection at centre. (Inch.)	Load. Tons.	Deflection at centre. (Inch.)
30	Nil.	70	$\frac{15}{16}$
35	$\frac{1}{4}$	80	$1\frac{1}{8}$
40	$\frac{7}{16}$	90	$1\frac{1}{4}$
50	$\frac{9}{16}$	100	$1\frac{9}{16}$
60	$\frac{3}{4}$	110	2

The floor-plates ultimately collapsed by the total rupture of the T-irons at 163 tons, and with a deflection of 10in.

In the preliminary stages of manufacture of the floor considerable difficulty was experienced. The plates were heated in a furnace and were bent in a hydraulic press by dies to the required form, but it was found that in cooling the extreme ends curled upwards and spread outwards. After many trials and by giving the dies a "set" in opposite directions, and by fixing the plates in a simply-constructed frame to cool, truth and uniformity in the shape of the plates was eventually secured. The rivet-holes along both edges of the plates were then drilled simultaneously by special machi-

Digitized by Google

nery. The system was brought to such perfection that from a single heating-oven and press, and from one drilling machine, occasionally forty to forty-five plates, or sufficient to floor the viaduct for a length of 100ft. to 112ft., were turned out daily, bent, drilled, and ready for fixing. At the final operation 344 plates were pressed in six days by one gang of men. The last day's work amounted to 64 plates. When the plates are ready bent and

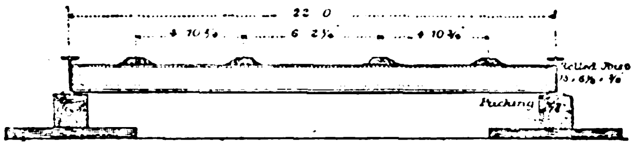

Fig. 4.

drilled, a T-iron is riveted between them at their springing. The rivets are closed up by means of machine-riveters, both heads being easily accessible from the under side. The rivets were put in by each machine at the rate of 400 per hour. The flooring was made by means of a special plant erected at the northern end of the railway for the purpose, and the girders were delivered by rail at that point.

Erection.—The structure was so designed that the spans could be put together and riveted up with floor complete at any part of the railway, and be then transported over the completed portion of the structure and placed in position. With the exception of a few ordinary and the four or five bowstring-spans and the opening bridges, the whole of the spans were erected at the north end of the railway. In this way the erection of staging, and consequent interference with the traffic in the streets and upon the dock estate, the expense of cartage, as well as the use of rivetters' fires in the midst of the dock property, were almost entirely avoided. The girders were lifted by travelling cranes on to supports above the deck of the structure at the north end, where the flooring was attached to them, thus making each span a complete bridge—a 50-foot span and its flooring weighing about 22 tons. They were then placed upon a trolley at such a level as to be higher than the main girders of the structure; the trolley travelled on the two outer rails of the permanent way, having a gauge of 16ft., and at first was hauled by horses on the roadway below, but later by a specially-designed steam-locomotive along the already completed portion of the structure.

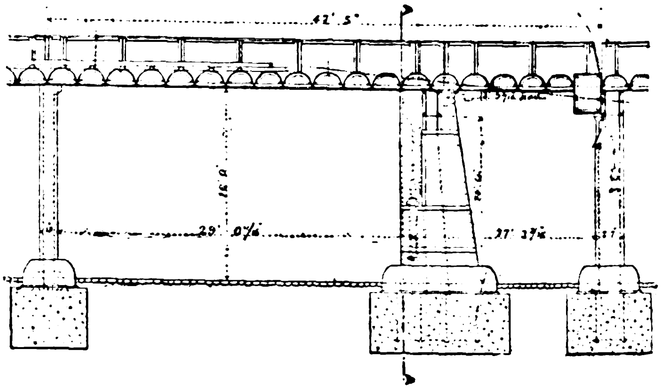
A special form of erecting-apparatus was provided, consisting of two lattice-girders standing upon legs resting on the ground at the front end, and at the hinder end supported on the girders already in position. These lattice girders were placed at such an altitude as to allow the trolley carrying the succeeding span to be rolled along underneath them. On these lattice-girders were placed two travelling cranes, so arranged as to lay hold of the spans on arrival, run them forward, and deposit them in their permanent positions upon the columns which had been erected in advance. The average time occupied in attaching the traveller to a span, running it forward and finally dropping the span on to its bearings, was one hour. The apparatus was then again run forward ready for the next span. Occasionally as many as twelve spans, of 50ft. to 70ft. each, were thus fixed in their permanent positions in five and a half working days—representing about 650ft. of finished viaduct—and from first to last this was effected without a single mishap. The total number of spans is nearly six hundred.

Swing-Bridge at Stanley Dock.—The design of the swing-bridge at Stanley Dock presented some difficulty, but was successfully accomplished by Mr. F. Hudleston. Owing to the constant traffic, both of vessels through the dock entrance and of railway and omnibus traffic passing over the old bridge, it was impossible to stop the way for more than a very short period; and the cramped nature of the available space added greatly to the difficulty of the problem.

It was decided to use a solid pivot, of cup-and-ball form, somewhat similar to that at the Hawarden Bridge,* which has fully answered its purpose. The bridge is in two halves, meeting in the middle of the dock entrance. On the level of the dock rails a double line of railway is provided for dock traffic, and on the upper level a double line of railway for the Overhead Railway, thus constituting a double-deck bridge. The lower level is arranged with bascule leaves, so that barges and small craft can pass through without the necessity of swinging the bridge and interrupting the railway. The bridge is actuated by hydraulic power obtained from the Hydraulic Power Company's mains. To enable the bridge to be completely opened, the following movements have to be made: The bridge is, in its normal position, a fixed structure resting on bearing-blocks at the tail end, and upon two legs at the front of each abutment. The first act is to lift very slightly the tail end of each half so as to allow the bearing-blocks to be withdrawn; this done, the tail end is lowered until the rollers rest on the tail-race; and in doing this the pivot of the bridge comes into contact with its cup-bearing, canting the girders upward at the nose end and lifting the legs from their supports. When this operation is completed, each half of the bridge rests on its pivot and on rollers on the tail-race, and is then ready for swinging.

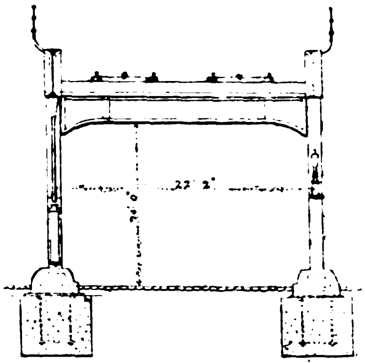
When the proper opportunity presented itself for stopping the traffic, which occurred at a holiday time, the erection of this structure was preceded by the removal of the existing bridge. The powerful floating-crane "Atlas" belonging to the Dock Board was of great assistance in this work, and enabled the old girders to be lifted bodily out and sent away without delay; some necessary alterations to the masonry had then to be made, after which the erection of the new bridge was proceeded with. The weight of the old bridge was 150 tons, whilst that of the new structure is 600 tons, and within ten days of the commencement of the work, railway traffic on the dock lines was resumed.

Lifting Bridges.—At three points on the line of railway, bascule bridges of a very simple character (Figs. 5 and 6), also designed by Mr. Hudleston, with openings of about 35ft. each, are provided to permit the passage of large boilers and other high loads. Hydraulic rams, housed in the columns and connected with the Dock Board's



LONGITUDINAL SECTION.

Fig. 5.



TRANSVERSE SECTION ON LINE A.A.

Fig. 6.

hydraulic-power mains, serve to open and close these bridges. The girders are pivoted so that as the tail end is lowered the front end rises, the difference in length and weight being balanced by kentledge placed in a balance-box attached to the tail end. The shorter arm of the girder is 14ft. 6in. in length, and the longer arm is 33ft. 9in., and when open the girders assume an almost vertical position.

Stations.—The stations are of a very simple character and design, with the exception of those at "Pier Head" and "Custom House," which are somewhat more extensive. They consist of up and down platforms (island platforms being found to be impracticable), which are 120ft. in length and 10ft. in width, each provided with a staircase, turnstiles, ticket-office, and a waiting-shed. At "Custom House" and at "Pier Head" (St. Nicholas-place), the platforms are roofed, and duplicate staircases are provided, so as to keep the arrival and departure traffic distinct. It having been found by experience that unpleasant draughtiness results from carrying the station roof over the railway, the roofing in these cases only extends a little beyond the edge of the platform, leaving the portion over the railway unroofed. A carriage shed has been erected at the north end, with five lines of way running through at the rail-level, communicating by means of a hoist with the lines and the repairing-shops at the ground level, equipped with the necessary tools driven by electric motors.

(To be continued.)

LIMITED COMPANIES.*

BY GEORGE WREFORD.

Joint Stock enterprise has made rapid growth since the passing of the earlier Joint Stock Companies Acts some fifty years ago, and especially so since the principle of limited liability became firmly established by the Consolidating Statute of 1862. Undoubtedly the creation of limited companies for working large commercial and manufacturing undertakings has, upon the whole, had a very beneficial effect upon the trade and commerce of the country, and has been the means of keeping a good deal of money belonging to small capitalists employed in home industries which would otherwise have found its way into foreign channels. The principle of these co-operative undertakings has taken firm root in the country, in spite of certain abuses which have crept into the system of promoting and working them—abuses which may be roughly classified under three headings :

1. Those connected with the promotion and formation of limited companies.
2. Those arising in the administration and working of such companies.
3. Those relating to the winding-up of insolvent companies.

The Legislature has from time to time endeavoured to encourage the growth of joint-stock enterprise by affording facilities for the formation and working of limited companies, and has sought to provide remedies for some of the above-mentioned abuses.

Of late years the efforts of the legislature have, perhaps, been more particularly directed to remedying the abuses connected with the winding up of companies—as witness the Companies Act of 1890. This act, while aiming chiefly at the correction of the maladministration and delays incidental to the winding up of companies under the old systsm of procedure, bears also incidentally upon the two former classes of abuses, inasmuch as it provides for an inquiry by an independent public officer into the causes leading up to the failures of companies—causes originating either in their inception and formation or in their subsequent working. So far so good, but it seems to me that to some extent this is equivalent to locking the door after the steed is stolen. It is but scant comfort when you have been robbed to be informed by a public inquiry of the means by which the swindle has been accomplished. Far better to have prevented the robbery. In this sense the policeman may be more useful than the magistrate, even as "prevention is better than cure."

Undoubtedly the prevalent spirit of gambling is responsible for many of the abuses which exist under the first heading, and it would almost appear as though the small capitalist becomes the willing prey of the unscrupulous company promoter, although he does not forget to howl incontinently when he finds that in endeavouring to secure inordinate interest he has lost his principal. Granting, however, that, in the present complex state of society and of the ramifications of commerce, some interference by Government and Government departments is nowadays almost a necessity, I would venture to suggest that the Legislature might usefully intervene to apply some remedy for the first and second classes of abuses to which I have alluded, as well as to the third class. There seems to be an absolute necessity for the protection of small investors, who, from the causes I have mentioned, appear unable to protect themselves.

Companies frequently come to grief through going to allotment upon insufficient subscribed capital. The promoters having incurred responsibilities for the expenses incidental to the floating of a company, are naturally anxious the company should go to allotment at all hazards, so that they may recoup their outlay, and obtain their commission or profit.

Other companies are formed for the purpose of taking over bankrupt concerns, and are really frauds upon creditors rather than upon the general investor, because it often happens that no attempt is made to obtain capital from the public except by way of mortgage debentures. The issue of debentures is the sole object for the creation of these companies. Some remedy for the former branch of abuses might be found in strengthening the powers of the present Joint Stock Registry at Somerset House. I think I am correct in stating that at present the action of that department of the Board of Trade is limited to seeing that certain formalities are complied with—that the name of the proposed company does not infringe upon that of any previously registered company—that the prescribed number of persons have associated themselves together to constitute the company by signing a memorandum of association—that the objects of the company are lawful and that certain stamp duties are duly paid. These are necessary preliminaries, but they do not go far enough. Many small capitalists have, doubtless, invested their money in limited companies because they imagined that the act of their being "incorporated under the Companies Acts," and of the issue of Certificates of Incorporation, was a kind of Government guarantee of the *bonâ fides* of the concerns. Why should there not be a system of *provisional* registration embracing most of the above-mentioned preliminaries, the complete registration and issue of the certificate of incorporation being postponed until the promoters of the company can satisfy the Registrar that not less than two-thirds of the proposed capital of the company has been actually subscribed ? And further, why should not a certain percentage of such subscribed capital—say 5 per cent.—be actually deposited with the Board of Trade prior to the issue of the Registrar's certificate, and be held for a limited period, at 2½ per cent. interest, as a guarantee of good faith ? This would constitute a reserve fund for emergencies, and should not be touched until the company had paid certain prescribed dividends, except in the event of the winding-up of the company. In particular it should be exempt from the operation of any debenture issue, as also should uncalled capital be so exempt in all cases. I do not think such requirements as these would in any way limit legitimate joint-stock enterprise. On the contrary, they would tend to restore the confidence of the investing public—which has been rudely shaken of late. So much has it been shaken that many sound concerns offered for public subscription fall completely flat, especially if the promoters restrain their imagination, and promise only what they really believe can be safely assured in the way of estimated profits.

It might also have a very beneficial effect if authority could be given to the Registrar to require an independent report from experts upon the objects of the Company—the value of the property proposed to be transferred to the Company, compared with the price proposed to be paid—the profits of the middlemen—the probable chances of the success of the Company's operations, and the sufficiency or otherwise of the capital proposed to be subscribed for properly carrying out the objects of the Company. If the report on these points should be unsatisfactory the Registrar (subject to an appeal to the Court) should have power to refuse to issue his certificate.

Such an inquiry as I have indicated would certainly prevent the inception of many a bogus company, and nip in the bud many of the swindles at present foisted on the public in the form of limited companies. I am told that some such system as this obtains in Austria—perhaps even of a more inquisatorial character than the above would be.

The remedy for the second division of abuses connected with the formation of companies—those formed simply and solely for the purpose of issuing debentures—is comparatively simple. The object of the promoters in all these cases is the evasion of the Bills of Sale Acts. Every bill of sale or mortgage upon personal chattels given by an individual requires to be registered under the Bills of Sale Acts, otherwise it is void. But registration in such cases means publicity, and the creditors of a trader seeing a bill of sale registered against him promptly stop the debtor's credit, and take steps to recover their debts, so that a trader knows that the giving of a bill of sale is usually the immediate precurser of bankruptcy. A mortgage debenture, however, issued by a limited company, although it practically amounts to a bill of sale, does not require public registration. All that the Companies Act requires is that these mortgages shall be entered in a Register kept in the company's office. Hence the inducement to an insolvent trader to go through the form of registering his business as a limited "Company," and then mortgaging all the assets by means of debentures. If such debentures were brought within the provisions of the Bills of Sale Acts the inducement for registering such concerns as companies would disappear. A slight amendment of the Bills of Sale Act would be an effectual remedy.

Passing on to a consideration of the second class of abuses—those relating to the conduct and administration of the businesses of companies—it seems highly necessary to improve the tone of directorial as well as that of auditorial resposibility. I think that recent events in connection with the public examination of directors and officers of bankrupt companies, and the prosecutions of fraudulent directors must have a very beneficial effect in bringing home to the minds of directors the serious nature of the responsibilities of their position, and of the duties they owe to the shareholders whose interests it is their duty to safeguard, and impressing on them the fact that they occupy a fiduciary capacity, involving not only moral but legal responsibilities towards their *cestuique trust*—the shareholders. Logically there can be no ground for the notion that conduct, which in the case of an individual would be considered dishonest or reprehensible, ceases to be so when the misconduct is that of several individuals forming a Board of Directors acting in a corporate capacity. It would be well if Directors were imbued with the idea that equal if not greater responsibility devolves on them acting as such than would be the case if they were managing their own businesses. Notwithstanding the well-known fact that names of men of prominent social and political positions figuring at the head of a prospectus does undoubtedly influence investors in subscribing for shares in concerns so fathered, or rather, because of that fact, I would urge that gentlemen of social standing, but possessing neither business training nor commercial experience, should not allow their names

* From the *Chamber of Commerce Journal.*

Digitized by Google

to be associated with the directorate of public companies. The company promoter—wise in his generation—knows the value of such names at the head of a prospectus, and undue importance will no doubt still continue to attach to them in the minds of investors—especially those of the smaller class—notwithstanding the disclosures which have demonstrated the unreliability in these matters of having at the head of affairs even men of good position, of honourable and upright character, but wanting in the necessary business qualifications. An efficient and practical general manager—shrewd, reliable, and straitforward—with a thorough grasp of the business under his control, and directly responsible to the shareholders, would frequently be found to be a far more satisfactory officer than any Board of Directors; but in many cases Boards have their uses, and cannot be dispensed with.

The proper check either upon a general manager or upon a Board of Directors should be the auditor. An efficient audit is a matter of prime importance. But to be efficient and reliable the auditor must be independent. How can he be independent—thoroughly independent—under the present system of appointment? He is now practically appointed by the persons whose conduct and affairs it is his duty to criticise. If the criticism be honest and thorough, how long is he likely to hold his post? Theoretically the auditor is appointed by the shareholders. He may in the first instance be nominated by the promoters or the first Board of Directors, and when the shareholders meet in annual meeting the Directors and managers generally hold the key of the situation by means of the proxies of absent shareholders. Practically, therefore, the re-election of the auditor rests with the Board. If the auditor, then, has been too inquisitive, or has been rash enough to criticise the balance-sheet in the interests of the shareholders, he will probably have to make way for a more pliable man—one who is more amenable to the appointing power. Even accountants of good standing are not free from the influences I have indicated, and in order to leave themselves a loophole of excuse, if not satisfied with the state of affairs, and in view of the possible disastrous result, they are induced to give equivocal certificates instead of the form of certificate indicated in the Companies' Act.

It is quite evident, therefore, that if audits in future are to be effective, instead of misleading, not only must competent accountants be employed, but the position of the auditor must be independent, and his powers must be considerably increased. And with these changes his responsibility would also be much enlarged. The question for solution is: How can these results be obtained? Possibly only by further legislative interference. It is, perhaps, for some reasons regrettable that such interference should be necessary, but it seems to be inevitable. There appear to be but two alternatives, either the auditors of joint-stock or limited companies must be appointed by an independent authority, such as the Board of Trade, or the auditor, when once appointed, must be a permanent officer, holding his office until he either voluntarily resigns, or is removed by an extraordinary resolution of the shareholders for sufficient cause shown.

Further legislation is being sought by professional accountants, with a view of securing a higher standard of technical acquirements, and of maintaining high professional character and standing. The enactment of a measure making provision for these objects will pave the way for securing a rota of professional auditors from which the Board of Trade or Boards of Directors could select competent men, responsible to the Board as well as to the shareholders for the due and efficient discharge of their duties.

The auditor should be empowered to call for an independent valuation of the company's assets, at the company's expense, if dissatisfied with the values appearing in the books; and his duties should not be limited to mere matters of arithmetic, vouching, and correct copying. The audit of the accounts of a limited company is on an entirely distinct footing from that of the accounts of an individual trader. In the latter case the trader wants a check upon his cashier, his book-keeper, and other employés. As a rule, he does not want a check on himself. He may deceive himself as to the value of his assets if he pleases. He fixes the value of the stock-taking of his clerks or otherwise, he goes through his book debts, and determines which are "doubtful" and which are "bad," and the auditor is not concerned as to the correctness or otherwise of the trader's estimates. But in the case of a company, a different set of interests arises. Here the auditor, as the guardian of the shareholders' interests, and as the "watch dog," to prevent their being deceived or betrayed, is, in my opinion, bound to satisfy himself, not only that the figures on the balance-sheet are correctly extracted from the books; not only that the books have been properly posted; not only that the arithmetic is correct; not only to see that the assets are in existence; but also, and above all, to see that the values placed against the assets are fair and reasonable. If, to satisfy himself on this point, it is necessary to incur expense, let the necessary expense be incurred, it will be good outlay in the long run, so will the payment of adequate remuneration for the important services which I would have the auditor render to the shareholders. At present the fee voted to the auditor is frequently ridiculously inadequate to properly pay him for what he ought to do, but which he now too often leaves undone for that reason, and this probably to the secret satisfaction of the Directors and other officials of the company.

These remarks have extended much beyond my intention in commencing them, and I do not therefore propose to dilate upon the third and last class of abuses in connection with winding-up of limited companies. Recent legislation has already grappled to a great extent with these abuses; but there has, as yet, been scarcely time to form a reliable judgment upon the general effect of that legislation. Beneficial results have unquestionably accrued therefrom, and the question of the desirability of leaving the actual administration of the estates of insolvent companies more or less in official hands, is one upon which it would be out of place for me to offer an opinion. The commercial community will doubtless determine this question for themselves, when they have had the necessary experience to guide them in regard to the respective merits of official and non-official administration. And the parties chiefly concerned—creditors and shareholders—should exercise their unbiassed judgment on the point.

The foregoing comments indicate generally the views which have suggested themselves to me during many years' observation of the matters upon which I have touched.

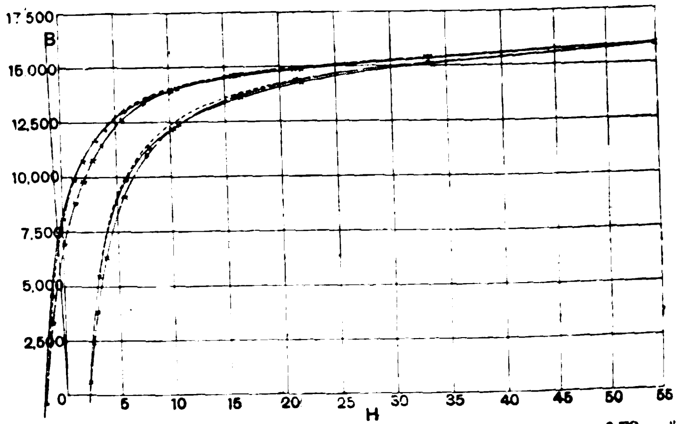
CORRESPONDENCE.

DIRECT-READING MAGNETIC APPARATUS.

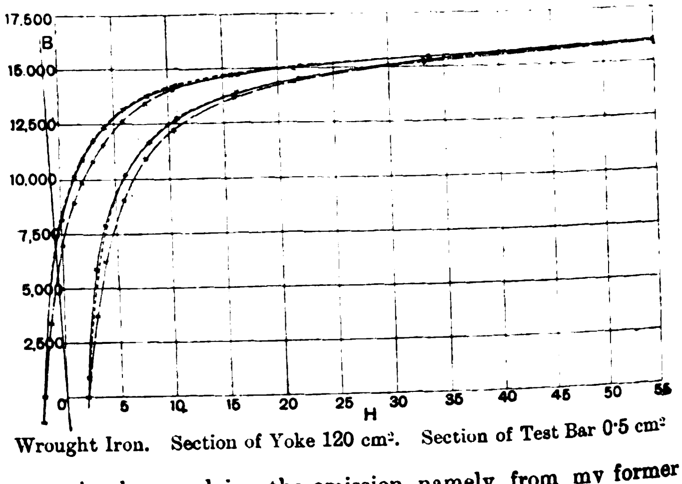
[TRANSLATION.]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In thanking you for the publication of my letter, I take the opportunity of remedying an omission of which you



Wrought Iron. Section of Yoke 120 cm². Section of Test Bar 0·78 cm².

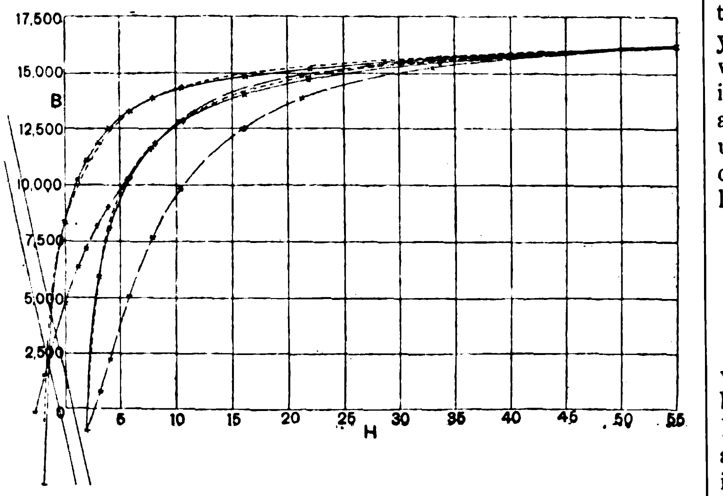


Wrought Iron. Section of Yoke 120 cm². Section of Test Bar 0·5 cm²

not unjustly complain; the omission, namely, from my former communication of the curves of magnetisation obtained by my apparatus, drawn to a larger scale. I hasten to repair this, and send you herewith the curves, which I hope may enable you to form an accurate idea of the capacity of my apparatus

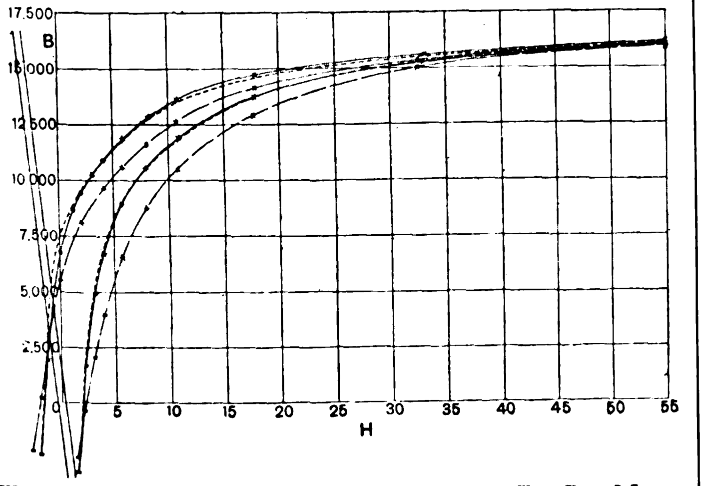
Digitized by Google

The full line curves are the magnetisation curves, determined by ballistic method, with a completely closed yoke; the long-dash curves show the direct readings of my instrument; and the short-dash curves are obtained from the latter by shearing. You will see from these curves that, with a ratio of section of



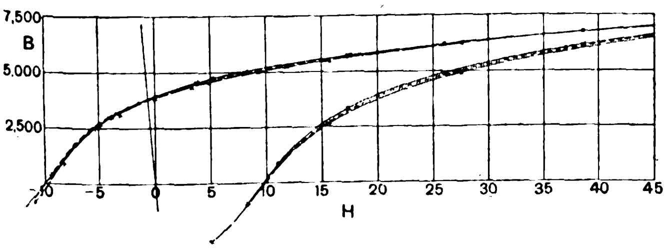
Wrought Iron. Section of Yoke, 120 cm². Section of Test Bar, 3·14 cm².

about 250 : 1 of the yoke and the test bar with wrought iron, and of 150 : 1 with cast iron, the direct readings of the instrument give values sufficiently accurate for practical purposes, without its being necessary to avail oneself of the shearing process. Further, it may be seen how the inclination of



Wrought Iron. Section of Yoke, 40 cm². Section of Test Bar, 0·5 cm².

the line of shearing alters with the ratio of the sections, and what happens at last when this ratio (with wrought iron) becomes smaller than about 100 : 1. The coercive force has then a value different from, and larger than, that obtained with a completely closed yoke; and this value rises as the section-ratio becomes



Cast Iron. Section of Yoke, 40cm² (Wrought Iron). Section of Test Bar, 0·27 cm² (Cast Iron).

smaller. The line of shearing becomes two similar parallel lines cutting the axis of abscissæ in two points each distant from the zero of ordinates by the difference of the coercive forces. A sufficient explanation of this remarkable phenomenon has not yet occurred to me; it seems contrary to theory; but I suspect that it may have to do with the coercive force of the yoke. It is therefore necessary in the construction of the apparatus to keep the ratio of the area of the yoke to that of the test bar as large as possible.

In conclusion, may I remark that if in your original Note, which has so often been mentioned, you had said "effect *on* the swinging coil," instead of "effect of the swinging coil," as you do in your repetition of the sentence, both I *and others* would not have misunderstood you. I am, therefore, far from imagining that you misunderstood the use of the compensation and its method of action, since this is made clear in the most unambiguous manner in your sentence itself. I only wished to correct the words quoted from your remarks as they might lead to misunderstanding.—Yours, &c., DR. A. KOEPSEL.

THE BURETTE-VOLTAMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I wish to state that the device of separating the developing and collecting parts in one and the same vessel has been already used by Maneuvrier and Chappuis (*Comptes Rendus*, 1888, CVII., p. 95), and Trouvé in his electric meter. A critical and historical Paper on the present burette-voltameter and its uses will soon be published by me, and I should be greatly obliged if any of your readers can refer me to other published descriptions of such gas-voltameters, or give indications about meters not brought to general notice, as, for example, Emmot and Ackroyd's, 1889.—Yours, &c., H. A. NABER.

London, W.C.

SINE CURVE ALTERNATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the mathematical treatment of alternating-current phenomena the assumption is usually made that the wave is of sine shape, and this assumption frequently justified by reference to the experimental tests of some pre-historic alternator, which just happened to give very nearly a sine wave, being in this regard very different from our modern ironclad alternators, which do not give anything like a sine wave. Only very recently this theoretical objection has been overcome by defining the sine wave used in the calculation as the "equivalent sine wave"—that is, a sine wave giving the same *effective value* and the same *power* as the true wave of the alternator, and therefore replacing it in practically all cases. An enormous amount of theoretical discussion has since that time been carried on to prove the superiority of the sine wave for motor work, for the efficiency of transformers, &c., and, I am sorry to say, mostly by theoretical men, who did not have any great chance to prove or disprove their theoretical conclusions by practical experience. A number of claims of superiority made for the sine wave could, however, be easily refuted already by theoretical considerations.

Take, for instance, the case of the efficiency of transformers. The hysteretic loss per cycle in the transformer exclusively depends upon the limiting values of magnetism, and will remain the same as long as these are the same. If the wave of E.M.F. is a sine wave, the magnetism will follow a sine wave also. If the wave of E.M.F. differs from sine shape, we can consider it as a fundamental sine wave with higher harmonics superimposed thereon, and then the wave of magnetism will also be a distorted wave, consisting of a fundamental sine wave superimposed by sine waves of triple, quintuple, &c., frequency. It is obvious now that if the triple harmonic wave of magnetism is superimposed upon the fundamental wave in such a way as not to increase its maximum value, the core loss will not be increased; but the amount of energy transformed is increased by the energy of the triple harmonic, for, as known, the energy of an alternate-current wave is equal to the sum of the energies of the individual harmonics, since

$$\int_0^{2\pi}\{\Sigma n\, a_n \sin(n\phi - \delta_n)\}^2\, d\phi = \Sigma n \frac{a_n^2}{2}.$$

In this case, the wave of magnetism will be flat topped, and thus the wave of E.M.F. peaked, hence of a shape like that

Digitized by Google

of the modern ironclad alternator. That means the sine wave of E.M.F. is not the most efficient for transformation; but the peaked form of wave, as given by the modern ironclad alternator gives in transformation a lesser core loss by from 9 to 10 per cent. Just here present I have no more recent tests at hand, and so am giving the experimental results of some tests carried out at the time when the introduction of the ironclad design of alternators was ventilated, and for this purpose careful tests made to find whether there was any difference in the action of transformers, between these machines and the old smooth core machines.

Hysteretic Loss.

Transformer.	With Sine wave (Watts).	With Ironclad wave (Watts).	Difference.
35,992	42·3	38·6	9·8 %
36,067	41·1	37·8	8·95 %
36,668	36·8	33·9	8·7 %
35,799	36·6	33·7	8·7 %

Average difference in favour of the distorted wave of the ironclad 9·03 per cent. (August, 1891.)

Coming now to the question of the influence of the wave shape upon the action of motors, I have always had some suspicion that the wave shape has been used as a scapegoat for explaining the inefficiency of a motor due to improper design. With the extensive introduction of induction motors in this country, it became necessary to see whether there was any difference in the action of a motor when operated by sine waves and by the waves of ironclad alternators. Tests, however, carried out by running one and the same three-phase induction motor—a properly designed motor, indeed—first from an alternator giving a sine wave, then from an ironclad alternator giving a sharp pointed wave, and, lastly, with a flat-topped wave given by reversing the current of the continuous current dynamo by a number of two-part commutators, showed no difference whatsoever in the action of the motor with regard to output, efficiency, starting torque, &c., except that in a few cases there seemed to be a slight advantage in efficiency in favour of the distorted wave of the ironclad alternator, probably due to the lesser hysteretic loss caused by such a wave. This difference, however, was too small to be definitely proved. Since that time induction motors and synchronous motors are built and used without further reference to the wave shape, and some thousands of kilowatts of motors in successful operation prove the correctness of this statement.

The question of resonance with higher harmonics—that is, of the dangerous rise of potential, which may occur in long distance transmission by the combined action of capacity and self-induction—can easily be disposed of by the fact that a transmission line, which is liable to give dangerous rise of voltage by resonance with the triple or quintuple harmonic, is not fit for use with the fundamental wave either.

These considerations, which, as before said, I found fully proved by practical experience, have completely convinced me that the superiority claimed for the sine wave is a mere superstition without actual foundation, and that in ordinary distribution work the sine wave is rather at a disadvantage in transformers, so that I have given up any endeavour to build an alternator with sine waves.

Thus I can only fully endorse the view taken by *The Electrician* in its criticism of sine-wave alternators, so far as the criticism is general.

To the particular machine, however, which started the discussion this criticism does not apply; but in this machine considerations entirely outside of the question of transformer efficiency or motor work have induced me to choose a design giving a practically perfect sine wave; conditions, however, entirely specific to the central station, for which this machine is intended, and therefore of no further interest for the present discussion, except in so far as they prove that even with an ironclad construction of alternator—which is indispensable in modern times—practically perfectly sine waves can be produced.—Yours, &c., CHARLES P. STEINMETZ.

August 10, 1894.

PATENT AGENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of May 11th last I referred to an editorial suggested by a misleading article in *Engineering*, and deprecated certain references to the Patent Agents Bills then before Parliament. I intimated that Mr. Warmington's Bill (promoted by the Chartered Institute) was not to be judged solely by its memorandum; and that all the honest and capable men of the profession were not in the Institute, and had no desire to be there under existing circumstances.

Both Bills were referred to a Select Committee of 11 members, who sat 16 times, and examined 15 witnesses. Evidence was given on behalf of the Board of Trade by its permanent secretary, the assistant secretary of the Railway Department, and the Comptroller-General of Patents. The Institute was represented by five witnesses, and the Society of Patent Agents by three, one of them being the writer. The evidence will shortly be issued, but I enclose a copy of the Special Report of the Committee, just published, and ask your permission to quote two paragraphs therefrom.

"The Committee do not consider that the Chartered Institute of Patent Agents, as at present constituted, sufficiently represents the general body of the practitioners at the Patent Office. Of the 245 registered patent agents only about 70 are members of the Chartered Institute, while another organised body of patent agents, the Society of Patent Agents, has 35 registered patent agents on its list of members, and many most respectable patent agents belong neither to the Chartered Institute nor to the Society.

"The governing body, having the control of the register and exercising powers of discipline, must represent not only the patent agents who are members of the Institute, but the larger number who are not members, and, accordingly, unless the Bill as amended by the Committee, or some measure on similar lines, should become law at an early date, the Committee are of opinion that the Board of Trade should remove the register and the appointment and control of the registrar and the examinations from the Chartered Institute, and make other arrangements to carry out the provisions of Section 1 of the Act of 1888. In that case the Chartered Institute should be required to pay over to Her Majesty's Treasury the balance of the fees levied under the rules of the Board of Trade, after providing for any proper expenses that have been incurred."

Your readers will see from these extracts that my statements have been confirmed by the report of the Committee; and that Mr. Alban Gibbs and others who backed our Bill were fully justified in doing so, as I claimed in my letter. Moreover, the evidence indicates that the aspersions upon "registered" agents, as compared with "chartered" agents, so freely scattered,* have no real foundation; and that the policy of the Institute has been to establish a selfish monopoly. I have already informed you that their charter is practically inoperative; and now that the Select Committee have declared that the Institute is not representative of the profession—while that is the first object for which it was formed—it remains to be seen whether the charter can be retained.

One further fact should be stated. The Committee selected Mr. Warmington's Bill for amendment, and having eliminated its objectionable features, and incorporated substantially our requirements, reported it to the House of Commons. The Institute, finding this amended Bill so little to its taste, has withdrawn it.—Yours, &c., J. SINCLAIR FAIRFAX,
Vice-President Society of Patent Agents.

433, Strand, London, W.C., August 20, 1894.

A Pocket Battery.—The Nassau Electrical Company, of New York, seem to have reached the least possible size and weight in a pocket blasting battery brought out by them. This battery is made up of chloride of silver cells, each being securely and hermetically sealed; these cells have an E.M.F. of 1·10 volts, with a maximum current of 2·00 amperes, weigh less than 1oz., are under ¾in. diameter, and less than 2¼in. long.

LEGAL INTELLIGENCE.

Re Woodhouse and Rawson United (Limited).

After the last public hearing (August 8th) of the examination in this case, Mr. Rawson put in a long statement of 129 pages, together with documents relating to various points referred to therein. Had the guarantee fund not been returned in debenture stock, Woodhouse and Rawson (Limited) would have had to be settled with by the handing over of securities or by having a charge upon the uncalled capital. In either case the debenture holders, shareholders, and creditors of Woodhouse and Rawson United would have been worse off under the special circumstances that arose. Three shareholders were chosen at the meeting in 1891 to examine the securities held by the Company, and they were perfectly satisfied. Most of the securities had a Stock Exchange quotation, and were taken at the market price, and in two cases even lower. Witness then put in a large amount of correspondence to show that the stock and plant valuations had been rigorously cut down, and that he and Sir Rawson Rawson had both gone carefully into the matter, and insisted upon reductions, notwithstanding what the managers stated with regard to the values. He then dealt with the evidence of Mr. Stutchbury, and gave 17 instances in which he alleged that the statements of that witness were incorrect. With regard to Mr. Stutchbury's analysis of trading in 1890-91, Mr. Rawson gave a large number of instances of mistakes in that analysis, and claimed that there was a profit in 1890, when he had charge of it, in every branch of the industrial business except one, which branch in the following year fulfilled the expectations he had held out. Quotations were made from various reports of meetings to show that the position with regard to industrial profits and profits made from the patent side of the business had been made clear to the shareholders. Shareholders who listened to his own statements at the meetings could not possibly have misunderstood the position. Documentary evidence was given to show that the industrial business of the Company largely increased in the first year, and had doubled by the end of the second year, notwithstanding that they were unable to manufacture the lamps. Mr. Rawson here went into the details of his interview with Mr. Pixley. He stated that Mr. Pixley was so very conservative with regard to the payment of dividend that he had even advised the non-payment in the previous year, when the guarantee fund, which had not been returned, absolutely compelled the payment of a 15 per cent. dividend, and therefore he did not attach so much importance to his advice when in the following year he advised that 5 per cent. instead of 15 per cent. should be paid. Witness drew attention to the large reserves after payment of the last dividend, the amount shown in the books being £46,996, and stated that if they had not written off various items which they were allowed by the Articles of Association not to write off, and had put in the shares at the quoted prices instead of in some instances below those prices, this amount would have been increased to £66,362. Even if the value of the shares in the Phœnix Trust and the Epstein Companies were taken at Mr. Stutchbury's estimate and the other unquoted shares at break-up prices, it would have left a balance to reserve of £17,296, or £36,662 if the amounts they could have added to the balance sheet had been added. He did not see any difference between paper profits which were not realised and profits represented by balance in hand or stock; for, if the securities were in companies intrinsically sound, as was the case in Woodhouse and Rawson United, they improved in value, whereas stock deteriorated. It would have been ridiculous not to pay a dividend simply because some of the assets were not realised in cash. This would, in his opinion, prevent most of the companies doing a financial business from paying a dividend. Coming to Mr. Edmunds's valuation of the patents, Mr. Rawson put in documents with a view to prove that that valuation was made for the Directors of the United Company. The Company dealt with their patents in a conservative way, as they only put in new patents at the cost of the patent fee and in fourteen years the total cost of their patents would have stood in their books at under £2,000, whereas in the ordinary course of business by that time they would have considerably improved in value. With regard to the suggestion that he had overestimated the profits in the first year in order to get a larger commission, he stated that in the first year they put various sums, amounting to over £5,000, to reserve, which turned out to be unnecessary, besides writing more off the patents than was necessary. All the shares that they held at the date of the balance-sheet were actually sold and paid for before the dividend was paid, and they actually had cash profits sufficient to pay the dividend. With regard to the Phœnix Trust he stated that Woodhouse and Rawson United refused to do a financial business, and that this Company was formed to underwrite various companies from the formation of which Woodhouse and Rawson made a profit which they would not otherwise have done. The industrial business was taken out of his hands after the first year, against his wish, and later, when it was put into the hands of Mr. Stutchbury, he objected to the arrangement on the ground that Mr. Stutchbury had not had sufficient experience, and he (witness) offered to pay half the cost of a competent manager. He gave other instances where he had differed from the Directors, and put in various documents to show that the goodwill of the subsidiary companies purchased was genuinely valued. Mr. Rawson went into particulars to show that the United Company did not do a financial business, there only being five pieces of business that could be called financial, and only two of these being strictly so-called. They never underwrote, never bought any shares in the market, never discounted acceptances for others or lent money, and, in fact, did not do a financial business in any way. Other electrical companies had just as much to do with the promotion of companies from which they made profits by undertaking contracts for works as Woodhouse and Rawson United who had got profits from the sale of patents to four different companies. He then dealt with the report of the Committee of Consultation, and gave twenty-two instances of statements made by them which had turned out in the examination not to be correct, and concluded by asserting that the points against the Directors which had been raised during the examination had all been fully explained and refuted.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

The 1894 Edition of "The Electrician" Electrical Trades' Directory and Handbook contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook is 7s. 6d. Postage in the United Kingdom, 9d.; abroad, 1s. 4d. *The 1895 edition is in active preparation.*

"Electric Lamps and Electric Lighting," being four Lectures delivered before the Royal Institution in April-May, 1894, by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is in preparation, and will shortly be published.

"The Work of Hertz."—The lecture delivered by Dr. O. J. Lodge at the Royal Institution on June 1st is being reprinted with corrections and additions, and many illustrations, and will shortly be ready, price 2s. 6d.

"Electromagnetic Theory," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"Drum Armatures and Commutators."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"Electrical Engineering Formulæ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

Tenders Invited.—The Portsmouth Town Council invite tenders for wiring and lighting by electricity the Technical School in Arundel-street, Landport. Tenders must reach the Town Clerk not later than Tuesday next.

Tenders Accepted.—The Electro-Chemical Company (Limited) have received the following tenders for engines and dynamos for the first section of the Company's plant, viz., 1,000 E.H.P., with water consumption guaranteed under a penalty of £1,000 per pound of water:—

Parsons and Co.—2 steam turbines, 15¾lb., 1,100 E.H.P. (accepted)	£4,800
Yates and Thom—horizontal engines and Holmes dynamos, 15¼lb. with extras, about	8,300
Willans and Robinson—4 engines with Holmes dynamos	9,700
Ditto—4 engines with Crompton dynamos	9,950
Ditto—4 engines with Siemens dynamos	9,980
Ditto—4 engines with Mather and Platt dynamos	10,100
Electric Construction Company (Limited)—4 Willans engines and E.C.C. dynamos, 17·384lb.	10,023
Easton, Anderson and Goolden—17¾lb., with extras	8,816
Ditto—Willans engines	£10,850 to 11,140
Musgrave and Sons—engines only, 13½lb. per I.H.P.	6,224
Crompton and Co.—4 Willans engines, 17¼lb.	£10,780 to 11,140
Johnson and Phillips—dynamos only	2,675

The water consumption is under 160lb. per square inch, and includes steam used for feed and condenser pumps. Messrs. Parsons and Co.'s tender was recommended for acceptance by the consulting electrician (Mr. J. Swinburne), and has been accepted by the Directors. Mr. T. Beeley, of Hyde, Manchester, has secured the contract for the boilers.

——— The Sunderland Corporation have accepted the tender of Messrs. Blakeborough and Sons, of Brighouse, for supplying grip boxes and connections for street lighting.

——— The Southampton Harbour Board on Tuesday, on the recommendation of the Works Committee, decided to accept the tender of Messrs. Crompton and Co. for the electric lighting of the Town Quay for the sum of £789. An amendment was moved that the tender of Messrs. Roger Dawson and Co., which amounted to £654, be accepted, but after some discussion this was rejected, and the report of the Works Committee adopted.

——— The Bootle Town Council have accepted the tender of Messrs. W. and J. Robinson and Co. for the necessary work and fittings required in connection with the lighting of the Town Hall tower clock by electricity, for the sum of £195.

——— The Electric Lighting Committee of the Hull Corporation on Monday considered the tenders received for the supply of a new engine and dynamos required for the extension of their electric lighting scheme, and decide to accept the tender of Messrs. Willans and Robinson (Limited) for the engine, and that of Messrs. J. H. Holmes and Co. for the dynamo, at £1,247 and £1,250 respectively.

DISSOLUTION OF PARTNERSHIP.—Messrs. Donnison, Parmiter and Barber, electrical and mechanical engineers, of Manchester, London, and Southampton, have dissolved partnership. The debts of the old firm will be paid by Messrs. Parmiter and Barber.

BANKRUPTCY.—Messrs. Queen and Co., the well-known manufacturers of scientific instruments, of Philadelphia, have been compelled to make an assignment for the benefit of their creditors. The failure is attributed to the continued depression in business, and to inability to make collections. The firm was established in 1853 by J. W. Queen, who sold the business, a number of years ago, to Samuel L. Fox, who had afterwards several partners associated with him. In 1893 the Company was incorporated.

——— Under the failure of Arthur Shippey, of 13, King-street, Cheapside, London, notice is given by the Official Receiver that the first meeting of creditors will be held at Bankruptcy Buildings, Carey-street, W.C., on the 28th inst., at 2:30.

LIQUIDATIONS.—The shareholders of the Domestic Telephone Company (Limited) resolved, at meetings held on July 18th and August 9th, that the Company be voluntarily wound up, and that Mr. J. R. Gibson, 24, Fulham-road, S.W., be the liquidator.

——— It was resolved at a meeting of the International Electric Subway Company (Limited), held on August 9th, to voluntarily wind up the Company; Mr. W. C. Grimwade, 32, Walbrook, E.C., to be the liquidator.

——— In the matter of the Collier Audible Telephone Syndicate (Limited), in liquidation, the Board of Trade have appointed Mr. S. Wheeler to be the Official Receiver. The first meeting of creditors will take place at 33, Carey-street, W.C., on the 31st inst., at 11 a.m.

——— A meeting of the Trent Gas Engine Company (Limited) is to be held at King John's-chambers, Nottingham, on September 17th, at noon, to receive an account of the winding up.

APPOINTMENTS VACANT.—The Electric Lighting Committee of the Halifax Town Council require an assistant electrical engineer and a foreman to take charge of the underground mains. Applications must reach Mr. Keighley Walton, town clerk, not later than 10 a.m. on Friday next, the 31st inst. Some further particulars appear in our advertisement columns.

——— The Battersea Polytechnic Institute require an assistant lecturer in Mathematics and Physics. Applications for particulars must be made to the secretary before August 30th.

THE PROPOSED PACIFIC CABLE.—The following is from the *St. James's Gazette* of yesterday :—

"The *Ottawa Citizen* states that the Canadian Government is sending to England forms of tenders and specifications for the proposed Pacific cable, and that contractors will be invited to send in tenders by November 1st. The information offered will be obtainable at the Canadian High Commissioner's office in London, and probably also at one or two other convenient centres in Great Britain. Intending contractors will be asked to furnish estimates for the laying of the cable by one or more of the eight available routes. These are all scientifically plotted in a large chart of the Pacific and Indian oceans, showing the coasts of British Columbia, Australia, and New Zealand, with the intervening islands available for landing places. The ascertained distances between the salient points of the several routes are marked on each.

The Available Routes.

There is a tabular description of each of the proposed routes. In these Tables the distances are given in knots, or nautical miles, the nautical mile being about one-sixth longer than the statute mile. The several routes suggested are :—

1. From Vancouver, B. C., to Norfolk Island, viâ Fanning Island, Fiji, and Norfolk Island, with branches from Norfolk Island to New Zealand and Queensland in Australia ; total distance, 7,175 knots.
2. From Vancouver, viâ Necker Island, Fiji, and Norfolk, with branches to New Zealand and Australia ; total distance, 7,145 knots.
3. From Vancouver, viâ Necker Island, Gilbert Islands, Fiji, New Zealand, and the Solomon Islands to Queensland ; total distance, 8,264 knots.
4. Viâ Necker, the Gilbert and Solomon group (omitting Fiji and New Zealand) to Australia ; total distance, 6,246 knots.
5. From Vancouver, viâ Necker and Fiji, to New Zealand ; total distance 6,127 knots.
6. From Vancouver, B.C., via Honolulu (2,280 knots) and Fiji, to Norfolk Island, with branches to New Zealand and Australia ; total distance, 7,078 knots.
7. From Vancouver, B.C., to Australia, viâ Honolulu and the Gilbert and Solomon Islands ; total distance, 6,293 knots.
8. From Vancouver to New Zealand direct, viâ Fiji, with a middle section if available ; total distance, 6,030 knots.

The Requirements.

Contractors are to base their calculations upon three several propositions for the construction, maintenance, and operation of the cable.

The first requires an estimate of the cost of laying a cable to be owned and controlled by the Governments interested to be worked under Government authority, and to be kept in repair for three years by the contractor.

The second is for a cable to be owned, maintained and worked by a subsidised company, the tenders to state how much subsidy would be required and for how many years. The tenders under this form are also to be based upon maximum cable rate of 3s. per word for ordinary telegrams, 2s. for Government telegrams, and 1s. 6d. for press telegrams, to and from Great Britain and the Australasian colonies on messages between Canada and Australia.

The third form of tender is to be for a cable to be owned, maintained, and worked by a company under Government guarantees : contractors to furnish the capital, lay the cable, operate and maintain it, stating what guarantee of gross revenue would be required, the difference between gross earnings and the amount guaranteed to be made good each year to the Company by the Governments interested ; and the Company to charge the same rate as specified in the second form of tender.

Some of the Conditions.

Among other conditions it is stipulated that the cable must be able to transmit at not less than the rate of twelve words a minute. Each offer must describe the character of the cable, its approaches, and cost of buildings, with provisions for repairs. Also, in the case of tenders based on the first form, contractors are to state the number of steamships required which, together with the stores, are to remain the contractors' property for three years, when they will be taken over by the Governments at a valuation. Contractors are required to take all risks of landing places for the cable, the Governments undertaking to secure landing places at the several points mentioned."

RE WOODHOUSE AND RAWSON UNITED (LIMITED).—It is announced that the whole of the stock now at 88, Queen Victoria-street, E.C., and at Bradford, Birmingham, Glasgow, and Chiswick, consisting of electrical plant, apparatus, instruments, and accessories, is offered for sale until September 30th next. Particulars can be obtained of Mr. F. D. Leslie, Receiver and Manager, 74, Coleman-street, E.C.

TELEPHONIC STREET FIRE ALARMS.—We understand that the "call" for the fire in Silvester-street, Great Dover-street, S.E., a few days ago, involving also an order for the fire escape, was received at the headquarters of the Metropolitan Fire Brigade on the Single Wire Company's new combined telephonic fire alarm post and fire escape attendant's call, referred to in our article on Street Fire Alarms last week. The telephone was found to be even louder than when experimentally tried.

BROCKIE-PELL ARC LAMPS.—Messrs. Johnson and Phillips send us a copy of their catalogue No. 7 for August, 1894, which contains full descriptions, prices and particulars of various patterns of arc lamps, lanterns, carbons, &c., together with a long list of users.

EXPORTS OF TELEGRAPH WIRE AND APPARATUS.—During July the value of these exports reached a total of no less than £303,483, exports during the corresponding months of 1893 and 1892 being, respectively, £77,305 and £25,906. The following figures show the exports during the first seven months of this year as compared with similar periods in 1893 and 1892 :—1894, £1,187,224 ; 1893, £556,500 ; 1892, £701,741.

PROTECTION OF TRADE MARKS IN GERMANY.—The new law for the registration and protection of trade marks in Germany, which comes into force on October 1st next, in its main provisions as to what constitutes a trade mark and is registerable as such, conforms very nearly to the Trade Mark Section of the English Patent Law of 1883, and it also embodies provisions analagous to some in the Merchandise Marks Act of 1887. Foreign products which wrongfully bear the name and locality of a German firm or a registered trade mark, on entering Germany as imports or for transit, are liable to be seized by the Custom House authorities and confiscated. When an illegal mark on the goods cannot be removed the goods may be destroyed. Where German goods must bear a certain mark or signification on being imported into a foreign country to indicate that they are of German origin, or if such goods are not so favourably treated at the Custom House in respect of the trade marks as the goods of other countries, the Federal Council is empowered to subject goods imported into Germany from such foreign countries to the same restrictions, and, in case of violation thereof, to seize and confiscate the goods. All trade marks at present registered in Germany must be re-registered under the new law within the next four years—*i.e.*, before October 1, 1898.

ADVERTISEMENTS IN GOVERNMENT PUBLICATIONS.—A memorial has been presented to Lord Rosebery, on behalf of the members of the Newspaper Society, complaining of the insertion of advertisements in Government publications, thereby placing the Government Departments in direct competition with private trade enterprise. Several of the Government Departments (including the Board of Trade and Labour) now issue publications, and there can be no doubt that these journals, entering under specially favourable conditions in competition with the existing trade journals, are calculated to do serious injury to the latter from the fact that all expenses are borne by the Treasury, and canvassers and others have the advantage of the use of official stationery. It has hitherto been a universally recognised principle that periodicals issued under Government control should not accept advertisements, and this principle was, we believe, strictly adhered to prior to the publication of the *Board of Trade Journal.*

CATALOGUE.—Messrs. Peto and Radford, of Hatton Garden, E.C., have just issued a new catalogue giving prices and illustrated par-

Digitized by Google

ticulars of electrical apparatus, including pocket and portable accumulators, portable lamps, electric jewellery, instruments, switches and switchboards, &c. The jewellery shown includes scarf pins, hair ornaments, &c. The firm have put down a number of isolated installations, and accompanying the catalogue are testimonials from those for whom the work has been done.

Exhibition.—A centennial exhibition is to be held at Baltimore, U.S.A., in 1897, and is to be second in size only to the Chicago World's Fair. Major F. Brackett has been appointed general manager.

Abergavenny.—At the last meeting of the Town Commissioners it was mentioned that the report of an expert as to the lighting of the town by electricity was in hand, and when finished would be open for the inspection of the ratepayers.

Arbroath.—The Committee of Management of the Gas Corporation have resolved to oppose a proposed application by the Northern Electric Supply Company for a Provisional Order.

Ayr.—The Lighting Sub-Committee of the Police Commissioners have reported the result of their inquiries respecting a suitable site for the electric light station, and they consider the Burgh Stores in South Harbour-street to be the most suitable, in which opinion they are supported by Mr. Hammond. The Surveyor has been requested to survey and make a plan of the ground, and a meeting of the Town Council will then be held for the purpose of settling the matter.

Bath.—The Surveying Committee of the Town Council on Monday re-affirmed their decision to resist the application of the Bath Electric Light Company for a Provisional Order.

Blackburn.—Circulars have been issued by the Town Clerk to the tradesmen in the centre of the town, stating that in the course of the next two months or so the Corporation will be able to supply the electric light to consumers in Darwen-street, Church-street, King William-street, Victoria-street, Richmond-terrace, Libray-street, Market-place, and Lord-street, and that "if the demand in these streets is sufficiently great," the Council may authorise mains to be laid in some of the neighbouring streets. The charge for the light is to be 7d. per unit, and for motive power 5d. per unit. ——Messrs. Berry and Pope inform us that they have received the contract for supplying and fixing the electric light fittings for the Art Gallery, Free Library, and Museum for the Blackburn Corporation.

Broadstairs. — The Brush Provincial Company have communicated again with the Broadstairs and St. Peter's Local Board with reference to their proposed application for a Provisional Order. In reply to a previous letter the Board said the Company's application would be opposed; but at their last meeting they decided to take a neutral position in the matter.

Bromsgrove.—A public meeting was convened at the Town Hall on Monday to consider the subject of lighting the town by electricity; but, it being considered that the time (11 a.m.) was an inconvenient one, and that a larger attendance could be obtained if the meeting were held in the evening, it was decided to adjourn until Thursday (last) evening.

Church Lighting.—The Saul-street Chapel, Preston, including the vestries, schoolrooms, &c., is to be lit by the electric light, Messrs. Bennett and Druce being the contractors.

Coventry.—The Corporate seal has been affixed to mortgages of the general district fund for raising £2,000 at 3½ per cent. for electric lighting purposes.

Cooking by Electricity.—Mr. Alderman Ellis, J.P., Chairman of the Electric Lighting Committee of the Portsmouth Corporation, gave, on Wednesday last week, a dinner to the Committee at the Portsmouth Town Hall, the food for which was cooked entirely by electricity. Mr. Pyle, of King's-road, was the caterer, and although his *chef* and staff were quite unused to electric cooking, not the slightest difficulty was encountered by them in preparing the viands. The cooking appliances were supplied by the General Electric Company (Limited).

Dewsbury.—The Local Government Board have authorised the borrowing and expenditure by the Board of Guardians of a sum not exceeding £2,150 for lighting by electricity the workhouse premises and cottage homes.

Durban.—The Town Council have decided to obtain the best advice in England on a general scheme for lighting the borough by electricity, and have instructed the Borough Engineer to at once take such steps in the matter as are necessary.

Electricity and Gas.—The Chairman of the Liverpool Gas Light Company, at the meeting on Tuesday, mentioned that an additional charge of 4d. per 1,000ft. in the previous year had only produced two-thirds of the amount which might have been expected. That had been brought about by four causes: the competition of the electric light, bad times, brighter weather, and the increase in price. It would be a matter of satisfaction, he said, to know that it was not through electric lighting competition that they had suffered most severely. They continually found, as a matter of course, that some large works in the city were resorting to the use of electricity; but they must be prepared for that. The sum, however, that had been lost from changes of that kind during the year was comparatively small, and was not of a nature to give any anxiety to the Company.

Fareham.—At a special meeting of the Fareham Local Board, held on Thursday in last week, it was resolved to sign the contract for the purchase of the electric lighting company's undertaking at a valuation, and Mr. W. H. Massey and Prof. J. A. Fleming (or, failing him, Mr. Arthur Preece) were appointed valuers.

Glasgow.—The Telephone Committee of the Glasgow Corporation have discussed the agreement between the Postmaster-General, the National Telephone Company, and the New Telephone Company, under which it was pointed out that the Postmaster-General was left absolutely free to grant a licence to the Corporation of Glasgow. It was the opinion of many of the members that the terms of the agreement were such that it would be comparatively easy for municipalities throughout the country to take over the telephone system of the districts served by them. The further consideration of the subject has been adjourned till next session, owing to the decision of the Postmaster-General to wait till then before confirming the agreement with the National Company.

Great Yarmouth.—The Town Council have resolved to charge 6d. per unit for the supply of electrical energy. Mr. A. W. Ranken has been appointed clerk of the works for the installation.

Hampshire County Council.—The Council have instructed the Public Works and Buildings Committee to obtain an estimate for the wiring of the new county buildings at Winchester for the electric light.

Hanley.—Owing, doubtless, to the success of the electric light, the gas company have again reduced the price of gas in Hanley.

Larne.—At the last meeting of the Town Commissioners a letter was read from Mr. J. D. A. Norris, the receiver and manager for Messrs. J. E. H. Gordon and Co. (Limited) stating that the agreement for the public lighting had been passed by the Court.

Margate.—Notice has been given by two companies of their intention to apply for Provisional Orders to supply electricity to the borough.

Mill Lighting.—Messrs. Berry and Pope are putting down a complete electric lighting installation for the mills of the Monton Mills Company at Sabden, Lancs., which is to be lighted throughout, including the weaving sheds, by electricity. Over 400 lights will be used. About 150 lights are being added at the Hob-lane Shed, Brierfield, for Mr. J. S. Vaners.

Monmouth.—A special meeting of the Town Council was held on Monday, when the final report of Messrs. Bramwell and Harris on the combined schemes of sewage disposal and electric lighting was adopted. The cost is estimated at about £17,600. The Mayor stated that Lord Llangattock desired to illuminate The Hendre with the electric light.

Nelson.—The Corporation Technical Schools are to be lighted by electricity, the contract having been secured by Messrs. Berry and Pope.

Portsmouth.—At the dinner given by Alderman Ellis to the Electric Lighting Committee on Wednesday last week, Mr. Ellis stated that the electric lighting had achieved a success beyond that attained in any other town in the United Kingdom. Electricians from all over the world had visited the town, and had unanimously agreed that the Portsmouth installation was far superior to anything yet accomplished. There had been such a demand for the current that unless their plant was immediately enlarged they would, within a couple of months, be unable to supply any further applicants. There were already about 4,000 incandescent and 100 arc lamps wired, and about 1,000 more lamps were being wired. Another £5,000 would enable them to supply current to about half as many more lights as they were now running, and from that outlay they hoped to reap a revenue of £4,000 a year.——At the last meeting of the Town Council the Electric Lighting Committee were authorised to extend the supply of electricity through Unicorn-road to the Connaught Drill Hall, at an estimated cost of £265. The Committee were also authorised to extend their mains through Clifton-road, and also along Clarence-parade as far as the corner of South-parade at an estimated cost of £1,000. Application is to be made to the Local Government Board for sanction to borrow the above sums.——The Town Hall Committee were authorised to advertise for tenders for purchasing the electrical plant now in the Town Hall, which is not required now the electric light station is open.

Richmond.—At the last meeting of the Town Council Mr. Heasler undertook to supply at the next meeting of the Council a statement showing the total expense of the town in connection with

Digitized by Google

the electric light. The Council calls, and have also resolved that the fire engine house clock should be lighted by electricity.

STALYBRIDGE.—It is announced that the works of Messrs. Millburn, Sons and Co. (Limited) have been purchased by a London firm, and that they will shortly be reopened as a foundry and electrical engineering works. When in full operation 200 hands are employed.

SUNDERLAND.—The estimate of the Electric Lighting Sub-Committee for the half-year ending March 31st next, submitted to the last meeting of the Town Council, showed that £801 18s. 8d. will be required. The Highways Committee recommended that the charge for lighting be fixed at 6d. per unit, and for heating, cooking, or motive power 3½d. per unit. The estimates and recommendation as to charges were approved by the Council.

THAMES CONSERVANCY.—The new offices of the Thames Conservancy Board on the Victoria-embankment, of which formally possession was taken on Wednesday, are lighted throughout by electricity.

WAKEFIELD.—Complaints are being made that no action has been taken by the Electric Lighting Committee in the matter of lighting the town by electricity, although the report of the consulting engineer was received some time ago.

WINDSOR.—The Eton Rural Sanitary Authority have received a communication from the Board of Trade, notifying that the Windsor Corporation have applied for a revocation of the Windsor Electric Supply Order of 1890, and stating that, subject to any recommendations the Eton authority may wish to make, the Board of Trade propose to revoke the order forthwith. The Eton authorities desire to take no further action in the matter.

WOLVERHAMPTON.—The Town Council at their last meeting authorised the Lighting Committee to invite and accept tenders for the execution of the necessary work and the provision of fittings for the supply of electricity to the Town Hall, Market Hall, School of Art, Art Gallery, and Free Library, the cost not to exceed £2,000.

WORCESTER.—The Mayor has consented to perform the ceremony of opening the electric lighting works at Powick on October 11th, and the Mayoress will open the exhibition at the Public Hall in connection therewith.

COMPANIES' MEETINGS AND REPORTS.

The Cuba Submarine Telegraph Company (Limited).

The forty-sixth ordinary general meeting of this Company was held on Wednesday at the offices, 58, Old Broad-street, E.C., Mr. Thomas Greenwood (Chairman) presiding.

The SECRETARY (Mr. James Scott) read the notice convening the meeting.

The CHAIRMAN said: Gentlemen, the Directors are pleased to be able to present so favourable a statement of accounts as those before you. The receipts for the half-year have been £30 more than in the corresponding period of the previous year, while the expenses which have varied a little, as they usually do, have amounted in the aggregate to £31 more than in the corresponding period of 1893. The result is that the balance of net profits is the same, within £1, as it was twelve months ago. Fortunately, we have had no repairs during the past half-year. This is the

Digitized by Google

second half-year we have had no repairs, and therefore there appears no item in the accounts for any expenditure of that kind, whereas in the previous year there was a payment of about £1,647 for repairs. We have also added to the reserve against losses by deposits with banks only £1,000 as compared with £1,500 inthe preceding year, and as a consequence we are able to increase the amount carried to reserve fund by £2,500, and likewise to improve our balance carried forward to the next half-year. This, I am sure, must be highly satisfactory to you, and you will therefore, I hope, feel no difficulty in adopting the motion which I now move, namely,

"*That the report and accounts for the half-year ended June 30th last, now submitted, be received and adopted.*"

Mr. CHARLES W. PARISH seconded the motion, which was agreed to unanimously.

The CHAIRMAN : I have now to propose :—

"*That the following dividends for the half-year be now declared on the shares of the Company, viz., at the rate of 10 per cent. per annum, subject to income-tax, on the Preference shares, and 8 per cent. per annum, free of income-tax, on the Ordinary shares, payable on and after to-morrow.*"

Mr. ALEXANDER F. LOW seconded the resolution, and it was carried.

The CHAIRMAN : The Director who retires by rotation on this occasion is our old friend, Mr. Low. He has been a Director of the Company from the very beginning, and is the only surviving original member of the Board, and we have very much pleasure in supporting his re-election, which I beg to propose.

Mr. J. P. HOOPER seconded the proposition ,which was unanimously approved.

Mr. A. G. LOW moved :—

"*That Mr. John Gane be re-elected auditor of the Company for the current year, at a salary of 20 guineas.*"

Mr. F. DONNISON seconded the motion, and it was adopted.

The proceedings then terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.*]

ARIEL ARC LAMP SYNDICATE (LIMITED).—This Company was registered on August 16th with a capital of £20,200 in £10 shares, to enter into an agreement between Samuel S. Allin and C. S. Graham Lloyd, William H. Wood and John S. Chatterton, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, manufacturers of and dealers in electric and other lamps, and all kinds of electrical apparatus and appliances. The subscribers (with one share each) are: H. F. E. Capper, William G. Lloyd, Arthur Pollock, Henry E. Sanderson, Albert H. Bellingham, Aubrey F. Willoughby, and M. Gwynne-Griffith. The first Directors are Samuel S. Allin and C. S. Graham Lloyd.

BRIGHTSIDE FOUNDRY COMPANY (LIMITED).—This Company was registered on August 16th, with a capital of £25,000, in £10 shares, to carry on the business of ironfounders, engineers, makers of chilled rolls, and manufacturers of and dealers in metal goods.

MAURICE DONNE AND MORICE (LIMITED).—This Company has been registered in Edinburgh, with a capital of £10,000, in £5 shares, to take over and conduct the business of the Ayrshire Foundry Company (Limited).

SPELLER AND COMPANY (LIMITED).—This Company was registered on August 18th, with a capital of £5,000, in £5 shares, to carry on the business of manufacturers of and dealers in lamps and appliances for lighting and heating, gas and electric light fittings, &c.

SYNDICAT DE TRACTION PAR LE GAZ (LIMITED).—This Company was registered on August 17th, with a capital of £20,000, in £40 shares, to acquire certain inventions for France and the French colonies and dependencies relating in any way to the traction or propulsion of vehicles by means of gas, and to carry on the business of mechanical engineers, machinists, gas engine makers, suppliers of electricity, manufacturers of machinery and apparatus connected with the generation, storage, and distribution of gas and electricity, &c. The first Directors are Thomas H. Pearson, W. Clarkson and Henry P. Holt.

AFRICAN DIRECT TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to July 25th, and recently filed, shows that out of a nominal capital of £300,000, in £10 shares, 23,600 have been taken up, and the full amount called and paid.

AKESTER ELECTRO-MOTOR AND ACCUMULATOR COMPANY (LIMITED). The annual return of this Company, made up to March 25th, has been filed. The nominal capital is £5,000, in £1 shares, of which 4,348 have been taken up, and 3,500 of these have been issued as fully paid. The full amount has been called up on the remaining shares, resulting in the payment of £1,324. 12s. (which includes a sum of £475. 12s. received in respect of 652 forfeited shares), leaving £175. 8s. as yet unpaid.

BAILY AND GRUNDY, LONDON (LIMITED).—The statutory return of this Company, made up to September 5, 1893, was only recently filed. 125 shares had been taken up, out of a nominal capital of £10,000, in £10 shares. All these shares are said to have been issued as fully paid, although no agreement has been filed giving particulars of any purchase by the Company.

CUTTRISS, WALLIS AND CO. (LIMITED).—The annual return of this Company, made up to June 15th, has been filed. Out of a nominal capital of £10,000, in £5 shares, 771 have been taken up, and of these 420 were issued as fully paid. The full amount has been called on the remainder, resulting in the payment of £1,755.

EASTON, ANDERSON AND GOOLDEN (LIMITED).—The statutory return of this Company, made up to June 4, 1894, was recently filed. The nominal capital is £200,000, divided into 10,000 Ordinary and 10,000 £6 per cent. Cumulative Preference shares of £10 each. All the Ordinary and 5,486 Preference shares have been taken up, of which 9,320 Ordinary and 2,886 Preference have been issued as fully paid. The full amount has been called and paid on the remaining 2,600 Preference shares, whilst up to the present no calls have been made on 680 Ordinary shares.

ECUADOR TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to July 19th, has been filed. Out of a nominal capital of £100,000, in £5 shares, 5,000 shares have been taken up and allotted. Upon each of these shares the full amount has been called and paid.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to August 9th, has been filed. The nominal capital is £1,000,000, divided into 150,000 "A" and 50,000 "B" shares of £5 each, of which 106,400 "A" and 23,564 "B" have been taken up. Of these 17,139 "A" and all the "B" were issued as fully paid, and the remaining 89,261 "A" shares were issued with £3 per share considered as paid. A call of 10s. per share has been made on these last-named shares, resulting in the payment of £44,630. 10s.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—The annual return of this Company, made up to July 10th, has been filed. Out of a nominal capital of £200,000, divided into 39,900 Ordinary and 100 Founders' shares of £5 each, 20,000 Ordinary and all the founders' shares were taken up. The full amount has been called on the latter class, while a call of £1 per share has been made on the Ordinary, resulting in the total payment of £20,500.

MANCHESTER EDISON SWAN COMPANY (LIMITED).—The annual return of this Company, made up to July 30th, has been filed. Out of a nominal capital of £550,000, divided into 50,000 "A" shares of £9 each, and 10,000 "B" shares of £10 each ; 20,000 "A" and all the "B" shares have been taken up and allotted. Upon the former, calls amounting to £1. 5s. per share have been made, while on the latter the full amount has been called, resulting in the payment of £124,770. 5s., and leaving £229. 15s. in arrears.

SHEFFIELD ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of this Company, made up to June 27th, was recently filed. The capital is £98,000, in 14,000 shares of £7 each, of which 8,625 have been taken up. 4,000 of these were issued with £5 per share considered as paid, and a call of £1 per share has been levied on the whole, and £8,625 has been paid in respect thereof.

CITY NOTES.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—Notice is given that the transfer books of the Four and a-Half Per Cent. Debenture Stock of this Company will be closed from the 25th inst. to September 3rd inclusive.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended August 19th were £861, as against £862 in the corresponding period of 1893, being an decrease of £1. The total receipts for the half-year amount to £6,064, as against £5,928 for the corresponding period of 1893, an increase of £136.

ENGINEERING AND GENERAL CONTRACT CORPORATION (LIMITED).—At the ordinary general meeting of the shareholders of this Company, held on Wednesday at Winchester House, after some considerable discussion a Committee of investigation into the affairs of the Company was appointed.

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The half-yearly coupons of the £100,000 Six per Cent. Debentures of this Company, falling due on September 1, 1894, will be paid by Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, E.C., on and after that date. Coupons must be left three clear days for examination.

THOMAS PARKER (LIMITED).—The first statutory meeting of Thomas Parker (Limited) was held on Friday, at Wolverhampton. Mr. T. C. Mander presided, and, after the usual formal business had been transacted, in response to a shareholder who inquired how matters stood with the Electric Construction Company in respect to the Eickemeyer Dynamo Winding Patents, he stated that the purchase of the patents had been completed, that the legal proceedings commenced by the Electric Construction Company remained as they were, but that the Directors were considering the question of granting a licence to the Company mentioned for the use of their patents on terms to be agreed. The Chairman announced that the erection of the works was rapidly approaching completion, and that there was every prospect of the Company at once entering upon a large and remunerative business.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended August 17th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,106.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts for this Company for the two weeks ending August 15th were £1,631, as compared with £1,856 for the corresponding period of last year. April receipts estimated at £4,976, realised £5,019.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 850.—Vol. XXXIII. FRIDAY, AUGUST 31, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

Her Majesty, by virtue of the power vested in Her by the "Weights and Measures Act, 1889," and by and with the advice of Her Privy Council, has been pleased to approve of the ohm, the ampere, and the volt. These standards, or more strictly "denominations of standards," now rank with the yard and pound, and may, we presume, be called, at all events for the present, Imperial. That this title is not officially given to them is, probably, no omission. Whether the diplomatic resources of the Foreign Office have been employed to invite other Powers to recognise and embrace these standards, we have no information, but it is well known that every care has been taken to insure their acceptance throughout the civilised world, and the necessary formalities can only be carried out with the deliberation customary in important negociations between Governments. The United States have no time for old-fashioned etiquette and conventional observances. In 1892 they adopted the *metre des archives* and the *kilogramme* of the Paris Bureau, and three months ago the House of Representatives passed a Bill legalising the ohm, volt, ampere, coulomb, farad, joule, watt, and henry, stopping short, for no obvious reason, from including Brown and Sharpe's gauge and the multiplication table. There can be but little doubt that, instead of Imperial, the ohm, the ampere, and the volt will become International standards. The specifications of the voltameter and Clark cell have been slightly modified, and we reprint them, with the Order in Council, for the last time, in another column.

The second half of Mr. Greathead's Paper on the Liverpool Overhead Railway will perhaps be of greater interest to our readers than the portion which we printed last week; but electrical engineers and electricians must not lose sight of the fact that it is only by the first-rate design and execution of the purely mechanical part of such an undertaking that success of the electrical part can be realised. In some respects this line is a simple one, for the power station is situated near the middle, and it was practicable to use a steel channel bar of 4 sq. in. in section for the conductor, without the use of feeders. The lightness of the motor cars enabled a comparatively light structure to be used, and resulted in a higher speed of the trains. With such a quick service—and the secret of success with such lines is a quick service—the time spent in emptying the carriages becomes important. The side doors greatly facilitate this, and entirely obviate the unseemly scrambling and kicking that is encouraged by end doors and platforms. The comparative tables of weights and tractive force are of considerable interest, but strict comparisons are hardly possible. Railway men contributed but little to the discussion on this Paper or the one which followed it; and as tramway men, of course, hope to benefit by the development of electric traction, nobody else but horse breeders and dealers are concerned in the matter. Though the chemico-dynamic efficiency of a warm-blooded animal is, we believe, as high as 40 per cent., horsey men have hitherto been silent on the subject. The very brief account of Mr. Timmis's electrical signals is given near the end of Mr. Greathead's Paper.

The article by Herren Rössler and Wedding, of which the first half is printed in another column, deals with the use of alternate currents for arc lighting. The subject may be divided into three parts. The first, concerning the regulation or feed of the lamps, gives a clear warning against a trouble which has annoyed several makers of arc lamps; namely, the necessity for adjusting springs, weights, and coil windings for the particular type of alternator with which the lamp is to be used. Some day we shall have names for the different kinds of curves: "hat-shape," "sugar-loaf," and others have been suggested, and "hog's back," "dromedary," and similar descriptions might be used, without having recourse to personalities—that is, to the names of well-known electricians. Meanwhile, we must refer to the three types of curve discussed in this article, by the names of the makers of the alternators, the Ganz or peaked curve, the Wechsler or slightly sheared sine curve, and the Siemens curve, which has a flat top and a final "kick." The advantages of the first of these is not very apparent. Unless Messrs. Ganz and Co. have modified it they no doubt can claim some good points for it. It seems to be for most purposes worse than a sine curve. The slight want of symmetry of the Wechsler curve need not concern us here—it is practically equivalent to a sine curve; nor need the little kick in the Siemens curve be noticed—the curve is a fair example of a flat top, the machine was a special one, and whether the shape of the curve has any connection with the peculiar work for which it was built, we have no information; the current (curve 11, Fig. 10) remains constant for more than half of the half period. This seems to be an admirable curve for many purposes. For arc lamp regulation it is vident that, with a given choking, more current passes than

Digitized by Google

with the Ganz curve; but the photometric result is of far greater importance. The second part of this Paper, which we shall print next week, deals particularly with the photo metric measurements.

In our last week's issue we gave an account of Prof. A. Schuster's Paper "On the Construction of Delicate Galvanometers," read before the British Association, in which he gives some interesting figures as to the ultimate sensitiveness it may be possible to attain with mirror galvanometers. It appears, however, that the basis of the formulæ is "the magnetic force at the centre of the coil for unit currents," which, as Profs. Ayrton and Perry pointed out some years ago, gives erroneous results when applied to the case of a magnetic needle of sensible length in comparison with the diameter of the coil. In the cases given in the Paper, where the coils are wound so near the needle, the error due to this method of calculation would probably be large. The great mathematical convenience of considering the force on a single magnetic pole in the centre of the coil, has caused nearly all galvanometer calculations to be made on this basis, but no calculations can be considered final in which the want of uniformity of the field is neglected. The consideration of the best type of magnetic system is a problem for which it is difficult to give any general solution.

In galvanometers where measurements are made by an image on a scale, the accuracy does not greatly depend on the diameter of the mirror, and it is advantageous to use a small light magnetic system and a small mirror, thus enabling the coils to be wound nearer the magnets, and giving small inertia and damping, which is important when using the instrument as a ballistic galvanometer. On the other hand, if interference or diffraction methods of measuring the deflection are used, a greater width of mirror would be desirable, and a consequent increase of the magnetic system. It is doubtful, however, whether much increase of sensitiveness would result from the use of such methods. With the present sensitive Thomson galvanometers, when supported in the best possible way, it is difficult to read to 5′ of arc when there is any local disturbance, and although it may be possible to detect an angle of 0·00005° with a mirror 1cm. wide, it certainly would not be possible to judge whether that deflection was caused by a current, or by vibration, magnetic disturbance, eccentricity, torsion, or electrostatic effects, most of which disturbances at present escape notice. On the whole, it is safe to predict that the time is far distant when we shall approach practically the sensitiveness given in Prof. Schuster's Paper.

The endeavours of the Société d'Encouragement pour l'Industrie Nationale to promulgate a new standard screw thread and wire gauge are very praiseworthy; but we should like to know if the B. A. thread, which was designed with careful reference to the Continental watch trades, and is based on millimetres and not inches, has been brought under its notice. Excellent as is the work done by committees of the British Association, the nature of these bodies is such that as soon as the work has taken the shape of a final report, and if no request for re-appointment is made, the committee ceases to exist, and no representative remains. Such committees consist, as a rule, of one or two zealous men, who initiate and carry out the work, one generally being the secretary, two or three other men invited to join on account of their supposed interest in the matter, and two or three ornamental or influential "deadheads." The British Association screw thread has become firmly established owing to its adoption by the Post Office, and to the steps taken by the London Chamber of Commerce to bring it to the notice of manufacturers, but not until several years after the Committee had been disbanded. The diameter is in round numbers of tenths of millimetres, and the pitch in round numbers of hundredths. To express these in inches, three or four decimal places respectively are used. It seems to be nobody's business to urge that this system should be used instead of the standards suggested by M. Thury for the Société des Arts of Geneva. For large screws, over six millimetres diameter, we can hardly expect the Whitworth system to be accepted, seeing that is based on the inch; but it is the practice in many engineering establishments on the Continent to express Whitworth threads roughly in millimetres, and to actually work with English stocks and dies or with tools made from English master taps.

Some five months ago a series of very interesting articles appeared in *The Times* on Light Railways, and in commenting on these in a leading article on April 6th last we discussed the cost and working expenses of the French *chemins de fer d'intérêt local*, and observed that the conditions under which such lines must be built and worked were very favourable to the use of electric traction with motor cars. In another column some further details will be found, together with a letter to *The Times* on the State Railways of India. The Indian railways, like much other Indian engineering work, have been a heavy burden on the taxpayers, and neither the cost nor the earnings can be allocated to the districts affected. The attempt to ear-mark the *intérêt local* in France and in Belgium is not satisfactory; and while the population of the district benefits in the cost of carriage, resulting in trade which would be otherwise impossible, and in the reduced upkeep of roads, the rates and taxes which pay interest on the cost of the railway, and on the deficit in working, if any, is paid for by others who derive no advantage whatever from the undertaking. This is one of the great advantages of State Socialism.

Cable Interruptions.—No interruptions are recorded this week.

Telephonic Communication in Russia.—Telephonic communication has recently been established between Nicolaieff and Odessa.

The Australian Association for the Advancement of Science.—The annual meeting of this Association is to be held at Brisbane, commencing January 11, 1895.

The Glasgow and West of Scotland Technical College.—The new session at this college will commence on October 1st. Further particulars, and information as to the courses of instruction, &c., will be found in our advertising columns, or may be had of the College Secretary.

Digitized by Google

Derby.—The local newspapers state that the electric light in Derby is not doing the best that the electric light can do. On Saturday night the streets appear to have had to rely upon moonlight for some time, owing to the accidental extinction of the arcs. These things ought not so to be.

Municipal Tramway Purchase.—At their first meeting after the recess, says the *City Press*, the London County Council purpose giving the necessary statutory notice of their intention to acquire the important section of the London Tramway system which runs between Kennington Park, by the Elephant and Castle, to London-bridge.

Electric Traction in Germany.—Electric traction is to be adopted on the tramway between Rheydt and Gladbach, as also on the tramways at Mulhausen. Plans have also been prepared for the construction of an electric tramway on the accumulator system between Hagen and Eckesey.

The Gohna Lake.—The Gohna lake, referred to in a recent number of *The Electrician*, reached the top of the dam on Saturday last, and is now several feet below the dam—on the other side. Thanks to the use of the specially-built telegraph line, the catastrophe was admirably "managed" by the authorities, and it may be said to have "gone off without a hitch."

Electric Traction in South Africa.—We learn by the last mail that an interdict was recently applied for in the Eastern Districts Court at Port Elizabeth, to prevent the Municipal Council giving effect to the resolution passed at a recent public meeting in the matter of the electric tramway extension. The Court, however, refused the interdict, the Council thus scoring a victory.

The Tramway Conference.—A conference of directors of tramway companies was held at the Guildhall, London, E.C., on Tuesday last, at the instance of the Tramways Institute of Great Britain and Ireland, at which Mr. W. J. Carruthers-Wain presided. It was stated that the share and debenture capital of the British tramway companies represents nearly £14,000,000 sterling, and that the decision of the House of Lords will seriously affect the capital value of this large sum. It was unanimously resolved to take immediate action to mitigate the ruinous consequences of the judgment of the House of Lords, and share and debenture holders are to be invited to sign a petition to the Board of Trade urging a fair consideration of their claims.

Electro-Chemistry in Austria.—A company has just been formed in Vienna to be known as the Consortium für Electrochemische Industrie. The Company has acquired some patents taken out by Dr. Carl Kellner, and is establishing works at Golling for the production of bleaching powder and caustic soda by the Kellner process. The works are excellently situated as regards the supply of raw material, while for motive power the water power of the Salzach is to be utilised.

Electric Lighting in France.—The municipal authorities of Aiguilte (Upper Loire) have just decided to establish an electric lighthouse on the Saint Michel rock. A central electric lighting station is to be established at Saint Rambert (Ain); water-power is to be utilised. Saint Rambert is a small town with important linen manufactories. A small central station has just been completed and put in operation at Gabian (Hérault). The plant comprises a Gramme dynamo driven by a 16-H.P. steam engine. The little town of Corbigny (Nièvre) is also to be lighted by electricity.

Chicago Exhibition.—A letter signed by 105 English exhibitors at the late Chicago Exhibition, and addressed to the Home Secretary, expresses obligations to those members of the British Royal Commission who visited Chicago, and acknowledges appreciation of the efforts of the British members of the jury. The writers place on record three points of vital importance concerning the administration of the British section. The first relates to the selection of an efficient executive officer and chief assistant, the second to the use of the headquarters of the commission as headquarters of the exhibitors, who, being denied other accommodation, were dependent on the generosity of the American authorities for a room in which to hold their meetings. The third point refers to the expenditure of £14,000 on the commissioner's offices and headquarters, which were practically of no service to exhibitors, and the expenditure of less than £3,000 on decorations of the British courts, whereby the exhibitors were placed at a great and most damaging disadvantage compared to every other nation exhibiting.

Lighthouse Communication.—The Royal Commissioners appointed to inquire into the means of communicating between lighthouses and lightships sat last Tuesday in Liverpool, and received evidence with respect to the lighthouses and lightships in and around Liverpool Bay, and as to the best means of supplying any existing deficiencies. The Earl of Mount-Edgcumbe presided, and the other Commissioners were Sir Edward Birkbeck, Admiral Sir F. Leopold M'Clintock, Admiral Sir George Nares, the Hon. H. Mulholland, M.P., Mr. R. Munro-Ferguson, M.P., Mr. J. C. Lamb, Mr. W. H. Preece, and Mr. J. A. Kempe; and Mr. Ernest Mogeridge, secretary. Mr. Harold Bateson, local hon. secretary to the Lifeboat Institution and coxswain of the New Brighton lifeboat, submitted a scheme for the improvement of the communications. The Commissioners afterwards paid a visit to Crosby Lighthouse, about six miles north of Liverpool.

Magnetic Rotary Dispersion.—Having carried on a series of experiments on the rotary dispersion of quartz in the infra-red part of the spectrum, M. G. Moreau is now investigating the magnetic rotary dispersion of carbon bisulphide for the same part of the spectrum He has also measured the refractive index of carbon bisulphide for the infra-red rays, so that he may be able to compare his experimental values for the magnetic rotary dispersion with those obtained by the formula deduced by Maxwell's electro-magnetic theory. The magnetic field used in the experiments was produced by the large coil which Verdet used in his classic researches in this subject, its intensity being measured by the rotation produced in carbon bisulphide for sodium light. In the infra-red observations a thermo pile and delicate galvanometer were employed. The author has succeeded in measuring the rotation for wave-lengths between 0·8 and 1·4 $\mu\mu$; the absorption of the CS_2 preventing any measurements being made for greater wave-lengths. The paper in which the above results are given will be found in the *Annales de Chimie et de Physique* for February.

J. and the Penny Ices.—A boy, supposes the *Engineer*, eats two ounces of ice. Let us see, says our contemporary, what is the approximate thermodynamic equivalent of the work he has made his interior do, assuming he takes five minutes to eat it. In melting the ice, taking the latent heat of fusion at 143 units, and the specific heat the same for the colouring and sweeting admixture as for the ice, he will require eighteen units to reduce the ice to water. To raise it in temperature to that of his inside, he will require seven more units, or a total of 25 British thermal units. Taking the mechanical equivalent as 777 foot-pounds, this will be equal to 19,425 foot-pounds. If the boy weighs 100lb. he will have called upon his stomach to do as much heat work as would, with a machine having unit efficiency, raise him 194ft. high, or a rate of heat extraction equal to nearly an eighth of a horse-power. Remarkable as this achievement appears to be, our contemporary will find that if the small boy is addicted to the pernicious habit of drinking a pint of ice-cold water in one minute he will, if his stomach acquires a uniform temperature in that time, expend a still greater amount of heat, for the power expended in that case will be equal to about three-quarters of a horse-power. How active a small boy can become on occasion!

The Electrolytic Purification of Sugar Juice.—In a recent number of *Sucrerie Indigène*, Dr. W. Bersch publishes some results obtained with the Schollmeyer-Behne-Dammeyer electrolytic process of purifying sugar juice. Dr. Bersch does not feel called upon to propound a theory of the process, but considers that the figures published cannot fail to give a fresh impulse to research work in this direction. The sugar juice coming from the diffusers at a temperature of 40°C. to 45°C. is heated up to about 65°C., and passed into a rectangular iron tank, divided into two equal compartments, of such a size that 330 gallons of liquid occupy a depth of about 18in. In each compartment there are seven zinc anodes of a total surface of 64½ sq. ft. The two compartments are alternately filled with juice, which is submitted for about 10min. to a current of from 50 to 60 amperes at 6 volts. A grey-green gelatinous

Digitized by Google

substance is deposited at the cathode; this deposit can be scaled off when necessary by reversing the current for 5min. or so. At Hoym (Germany), where this process has been tried, it is found that in defecating electrolysed juice 1 per cent. of lime does the work of the 3 per cent. or 4 per cent. required in the case of non-electrolysed juice. According to Dr. Bersch, the broad result of the electrolytic treatment is that a better quality of refined juice is obtained, and that in less time and with greater facility than formerly. The first cost of the plant at Hoym was paid for in a week by the superior economy of the process.

Standard Wire Gauges and Screws.—We have frequently had occasion to refer to the useful work, in the standardisation of screws and wire gauges, which is being done by the Paris Société d'Encouragement pour l'Industrie Nationale. The latest proof of this is to be found in the publication of a circular on the "Unification des Filetages et des Jauges de Tréfilerie." The Society has had the question of a standard screw-pitch and wire-gauge in hand since the end of 1891. It was, however, only three months ago, says *Nature*, that a meeting was held for the purpose of discussing the various systems suggested, and at that meeting the scales expounded in the pamphlet before us were accepted. To secure uniformity in the manufacture of screw-threads, the Society proposes a system, to be known as the "Système Français," in which the pitch increases in steps of half a millimetre, from a screw having a diameter of six millimetres and a pitch of one millimetre (No. 0) to one having a diameter of 148 millimetres and a pitch of 10·5 millimetres (No. 19). The formula which, in this system, allows the diameter (D) corresponding to any pitch to be deduced is $D = p(p+8) - 1{\cdot}5 \div 1{\cdot}3$, where p is any pitch expressed on the adopted scale. By means of this, it is possible to extend the new system to screws of any diameter, and the number of the screw of which the diameter had been thus determined would be equal to the number of half-millimetres expressing the pitch, *minus* two. For screws less than six millimetres in diameter the standard drawn up by M. Thury for the Société des Arts of Geneva is adopted. In addition to promulgating these standards of screw construction, the Société d'Encouragement has developed a decimal system of gauging wires. In this system, the numbers of the wires express their diameters in tenths of millimetres; thus, a No. 7 wire has a diameter of 0·7mm. Such a method of designating wires is as simple as it is scientific.

Specific Inductive Capacity in Variable Electrostatic Fields.—A recent number of the Johns Hopkins University *Circular* contained a preliminary note, by E. F. Northrup, on a method of obtaining the specific inductive capacity of solids under either slowly or rapidly changing fields. It is of great importance in connection with Maxwell's electro-magnetic theory of light that, since the refractive index for most substances has only been measured for very short waves, the specific inductive capacity be measured under such circumstances that the field of force alternates with such rapidity as to produce waves comparable in length to the waves with which the refractive index is determined. The apparatus employed by the author consists of three heavy brass plates, fastened parallel to each other, and separated by about three inches. Each plate is held in position by four insulating strips of ebonite, through the ends of which pass four iron rods with a screw-thread cut upon their whole length. To the centre of each of the two outside plates, and perpendicular to the plate, is fastened a brass tube. A rod, half of which is of ebonite, moves in this tube and carries at its end a thin plane plate of glass, the surface of which is coated with metal foil. These small movable plates are as nearly as possible parallel to the large plates, and their position is given by a vernier attached to the ebonite rods. The two outside plates are connected by a metal rod which carries a metal ball. Another ball, nearly opposite the first, is fixed by a short metal pin to the middle plate, so that the distance between the balls can be adjusted. In employing the apparatus to measure specific inductive capacity with rapidly-varying fields, the following arrangement is used. The two outside plates and one terminal of a large induction coil being connected to earth, the other terminal of the coil is connected to the middle plate. When the coil works, sparks pass between the balls, and oscillations are set up. The lines of force, when air only is the dielectric, divide evenly between the plates, and in the region of the small plates the field may be considered as uniform; hence, if these plates are at equal distances from the centre plate they will always remain at the same potential. If, however, a plate of some other dielectric is placed between the centre plate and one of the movable plates, in order that the two small plates may remain at the same potential, they will have to be placed at unequal distances from the centre plate, and from their relative positions the specific inductive capacity can be deduced. In order to "weed" out the effects of the slow changes of potential due to the charge and discharge of the coil, the two small plates are connected to the primary of a small transformer, the secondary of which contains a spark-gap. In this way the effects due to the slow changes are eliminated, since the rate of variation of the induction in the transformer, due to these slow changes, is not sufficient to raise the potential in the secondary to the 300 volts or more required to break down the dielectric in the spark-gap.

Educational Endowment in America.—It may be doubted whether American universities are altogether such as we should see, or like to see, founded in this country, were the same stream of gold to flow towards educational endowment here as on the other side of the Atlantic; but until our educationalists have an opportunity of handling millions it is obviously impossible to say whether they would make better or worse similar or dissimilar use of such colossal funds as are placed at the disposal of their colleagues across the water. The way they manage these things in the United States may very well be exemplified by the case of the Chicago University. Two years ago, said *Engineering* recently, it existed only in the minds of a number of zealous Baptists; to-day it has its broad acres on the Lake Front, an imposing pile of buildings, and a student population of 1,000. Chicago, we are further informed, is no longer a place merely of surprises and wonders; it has become a city of lofty inspirations and generous impulses. The new university owes its foundation to Mr. John D. Rockefeller, who, in June, 1889, offered £120,000 for the purpose, on condition that £80,000 more would be advanced by others. The character of the response pleased Mr. Rockefeller so much that, to mark his appreciation of it, he placed a cheque for £200,000 to the credit of the contemplated institution. Example now became contagious; a sum of £140,000 found its way into the University chest from the will of Mayor William B. Ogden; S. A. Kent offered £40,000 for a chemical laboratory; G. C. Walker, £20,000 for a museum; Martin A. Ryerson, £20,000 for a physical laboratory; Major H. A. Rust, £14,000 for a dining-hall; and Marshall Field, £50,000 for a biological laboratory. Next came Mr. Yerkes, who offered £100,000 for an astronomical telescope to surpass that of Lick. The name of Mr. Armour, the packer, is not to be found on this list, he being engaged in spending a trifle of £400,000 or so on an institute of his own. The lady friends of the university scheme came forward. Mrs. Henrietta Snell gave £11,000; Mrs. Mary Beecher, £10,000; Mrs. E. J. Kelly, £10,000; and Mrs. N. S. Foster, £12,600. The executive of the university, therefore, started operations with no misgivings as to funds—a feeling quite unknown in England. The buildings were begun in November, 1891, and when the Exhibition opened in May, 1893, seven were completed, at a cost of £180,000. The university has, at present, the three faculties of arts, science, and divinity. Chicago departs from time-honoured traditions in its regulations about vacations. It must be admitted that we devote too much time to holidays. On the other hand, the Chicago legislators are in imminent danger of erring in the opposite direction. By one drastic measure they abolish all long vacations. The twelvemonth is divided by them into four quarters, the last week in each being devoted to a little mental depolarisation. The regular work of the university is carried on by a staff of more than one hundred teachers. These are of various grades, from the professor and assistants through instructors and tutors down to readers and docents. Many are graduates of Harvard, Yale, Johns Hopkins; some, too, come from Berlin and Göttingen, while others owe allegiance to Cambridge and Edinburgh. The official head of the university is Dr. Harper of Yale.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(Continued from page 425.)

Feed and Steam Mains and Connections.

Feed Mains.—The life blood of a steam plant is the feed water, and, where the consequences of a failure in the supply of this vital fluid would be disastrous, precautions must be taken to ensure a steady supply of water to the boilers. Failure usually occurs from one or other of two causes: stoppage of the supply from the source, and breakdown of the

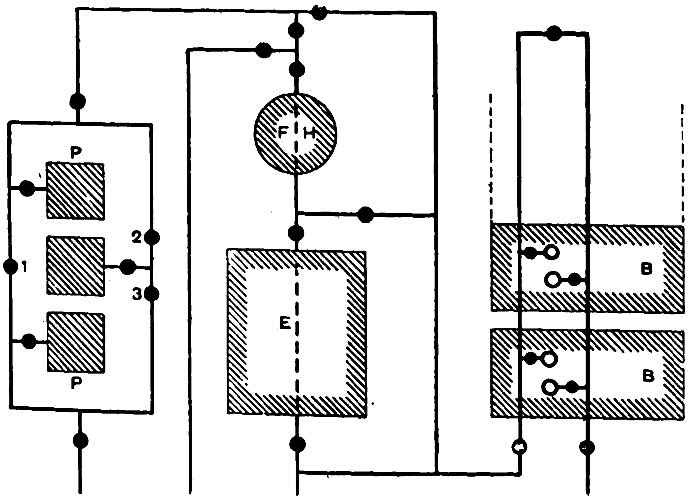

FIG. 20.——— Feed Pipes. ● Stop Valves. B, Boilers. E, Economisers. F H, Feed Heaters. P, Pumps.

main pipe or of the pumping plant. The remedy for the first is found either in a capacious cooling pond, in places where condensing plant is used, or in large tanks filled with cold water from the town mains. The remedy for the second lies in duplication or multiplication of the parts. It is insufficient for this purpose, however, to provide several pumps; it is also necessary to provide two or more distinct possible paths for the water, from the cooling pond or tanks to the battery of boilers, and, further, to provide each boiler with two injection or feed pipes. This is almost universally done now in

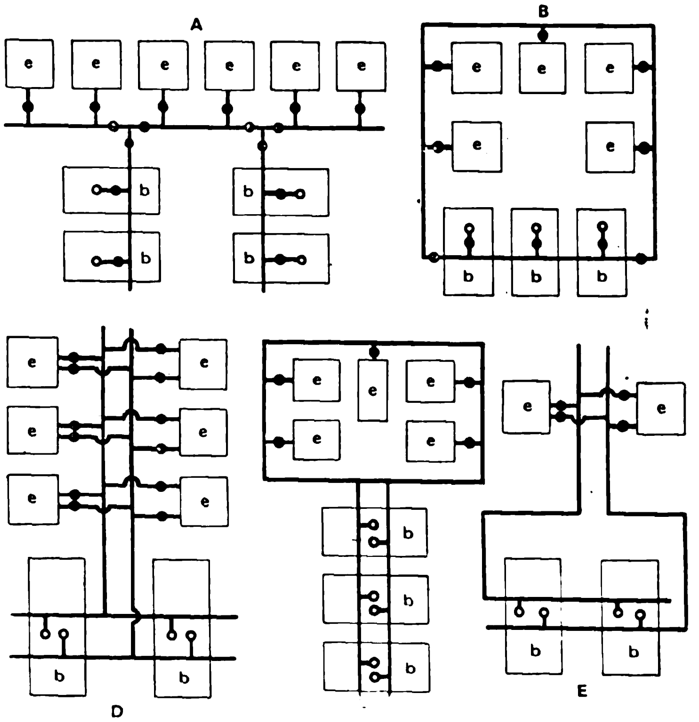

FIG. 22.—A, Ideal Single Main System. B, Single Ring Main System. C, Double Ring Main System. D, Manchester Independent Duplicate Main System. E, Portsmouth Independent Duplicate Main System. b, Boilers. e, Engines.

electric power stations. A diagrammatic representation of the feed main connections between a battery of boilers and three pumps, including an economiser and a feed-heater, is shown in Fig. 20, and may be taken as an average of usual practice. By closing the stop valves 1 and 2, two pumps will

supply all the boilers through one feed main; by closing the valves 1 and 3 the same result can be obtained through the other feed main; all the other valves being opened or closed as required. An elevation, to scale, of the feed connections at the Glasgow electric power station is shown in Fig. 21.

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

For permission to reproduce the illustrations of the Glasgow feed and steam systems, the author is indebted to Messrs. Alley and Maclellan, by whom the work was carried out.

Steam Mains.—This idea of duplication, if logically pursued, leads to the provision of two independent paths for the steam, from the boilers to the engines; for it is evident that where only one path is provided the working of the entire plant depends on the security of that one steam main. With steam distribution, however, there is an effect to be considered which does not enter into water distribution; namely, the loss of energy by radiation from the pipes, and the consequent injury to the steam by the production of wetness. Duplication of steam mains, therefore, can only be carried out at a sacrifice of some of the efficiency of the steam plant. Many engineers of very great experience are in favour of duplicating every steam pipe and main. Others, of equal experience, consider that it is quite as safe and certainly more economical to provide only one system of pipes, but to employ an unusually high factor of safety; and to so design the parts that repairs may be carried out and extensions made without crippling more than a fraction of the plant.

Where duplicate mains are adopted, it should be arranged that, when not required to supply steam, the several sections of the mains may be cut out of circuit, thereby reducing the loss of steam by condensation. In some places this is not possible, owing to the necessity for keeping the steam joints under pressure, and an enormous rate of condensation goes on all day and night long in consequence.

Systems of Steam Mains.—Besides the simple plan of providing a single main between the boilers and the engines, there are two systems of steam mains in general use. These are: the ring main, and the independent duplicate main. Diagrams of these systems are given in Fig. 22. With the simple ring main, including all the boilers and engines in its circuit, each item of plant gives or takes steam through only one branch. This is shown at B, and is in use at, among other places, the Amberley-road station of the Metropolitan Electric Supply Company. More commonly, the ring itself is divided into two rings or loops, one for the engines and one for the boilers, as shown at C, each of the boilers supplying steam at two points to the boiler mains. This system is in use at the Glasgow electric power station, a plan of the steam

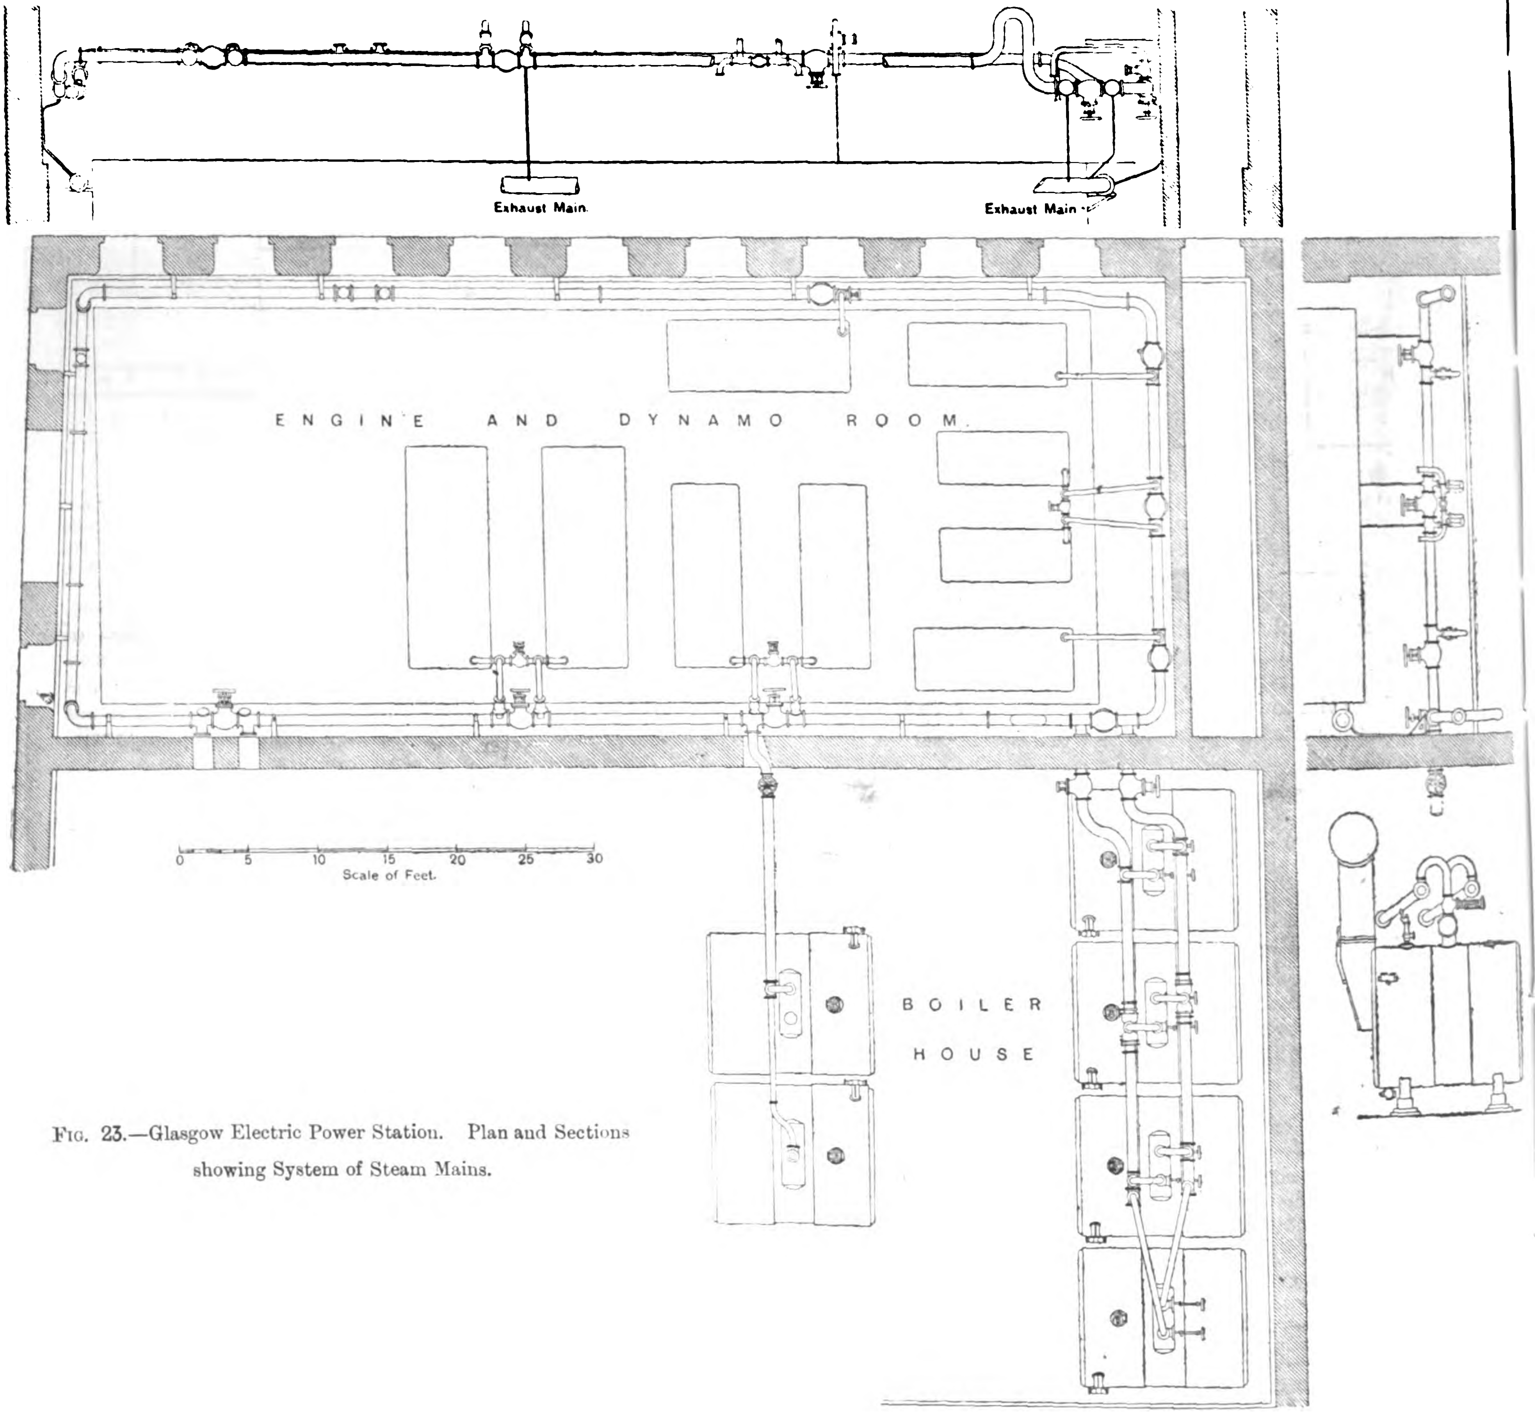

Fig. 23.—Glasgow Electric Power Station. Plan and Sections showing System of Steam Mains.

Digitized by Google

mains at which is given in Fig. 23. At this station a great deal of trouble from condensation has been experienced. Two systems of independent duplicate mains are shown at D and E, in Fig. 22. The former of these is the one adopted at the Manchester electric power station; the latter is in use at the Portsmouth station. It will be seen that the former requires a much shorter length of main, for the same size, number and arrangement of engines and boilers.

Steam Receivers.—It has been pointed out that, owing to the irregularities in the velocity of steam through the pipes, there must be a fluctuation of pressure at the engine end, even assuming the boiler pressure to remain constant. Where several engines are taking steam from the same main, it may happen that they all take steam at the same moment, in which case the fluctuation of pressure will be very large; on the other hand, it may happen that they take steam in succession, and thus produce a fairly uniform flow in the pipe, in which case the fluctuation would be practically zero. Where the engines are driving continuous-current dynamos

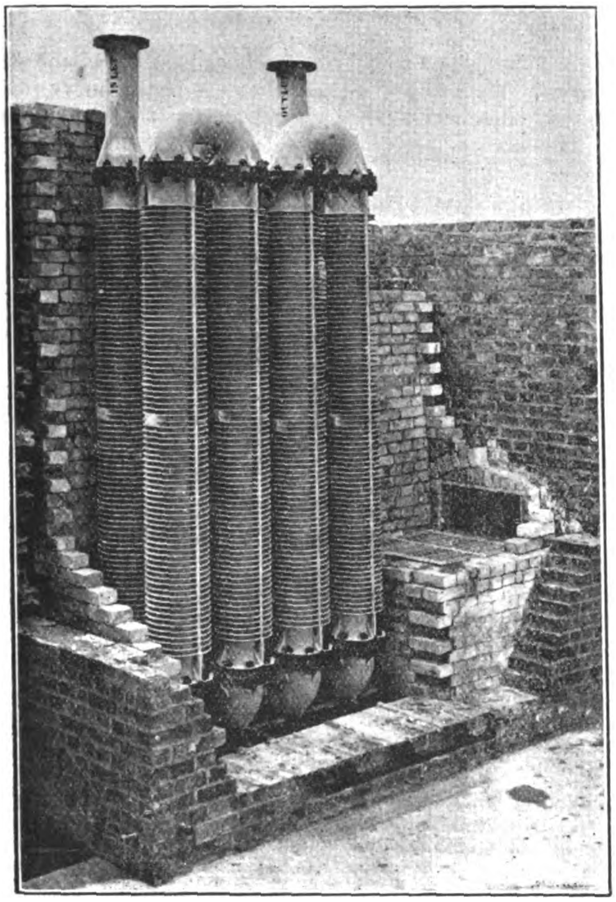

FIG. 24.—Schwoerer Superheater arranged for Independent Firing.

there is no tendency to produce any definite condition in this respect, and the engines probably come into and go out of steam-phase quite irregularly, producing complicated fluctuations of pressure in the mains. Where, however, the engines are driving paralleled alternators, the phase relation between the steam in-takes of the several engines is fixed. It is as liable, however, to be fixed badly as advantageously; for there is, at present, no attempt made to get the engines out of steam synchronism while getting the alternators into electrical synchronism. One remedy for the ills due to irregular steam-flow is to provide a small receiver or reservoir for the steam, placing it as near as possible to the engine. This will transform the irregular rate of flow into a regular rate, and will materially diminish the loss of pressure due to friction in the mains. A certain amount of condensation might be expected to take place in the receiver; but this would be less than in the receivers of compound engines, as the size might be smaller.

Superheaters.—One remedy for the evil effects of condensation in steam mains which has been proposed is to superheat the steam directly it leaves the boilers. The effect of superheating on the behaviour of the steam after it enters the engines will be considered later. Superheating, though it would without doubt reduce the condensation in steam pipes, would probably not diminish the heat losses due to radiation from the pipe surfaces; indeed, the superheated steam being hotter than the saturated, it would probably be found that these losses would be increased. A form of superheater which has been largely used in conjunction with Sulzer and similar types of engines on the Continent is shown in Fig. 24. This superheater is the invention of Mr. Schwoerer, and is manufactured in this country by Messrs. Fraser and Chalmers. From a report by Prof. Unwin on this superheater, it would appear that an economy of from 20 to 25 per cent. of coal may be obtained through its use in conjunction with the slow-speed engines just named. The superheater shown in Fig. 24 is arranged for independent firing, but superheaters are frequently set in the boiler flues so as to derive heat from the same fuel as the boiler. It is a saving in labour to adopt the latter plan, since a separate grate need not then be used. But it does not contribute to satisfactory and efficient superheating to place the heater in the colder parts of the boiler flues; and, for the best results, the gases brought to the superheater should be at least as hot as those taken to the boiler.

(To be continued.)

THE "SINE CURVE" CONTROVERSY.

In our issue of July 6th, on page 258, we observed that a considerable number of manufacturers in America are advertising the possession of a "true sine curve" as a valuable feature of their alternators. We returned to the subject a fortnight later, and on July 20th, on page 319, made some further remarks on the subject. After these were in type, we found that our views received full confirmation from some experiments which are being conducted with special reference to the efficiency of transformers, but which are not yet completed. The matter has now given rise to a considerable controversy, but is being led off the original line into cases of power transmission by special types of machines. Last week we referred to some foolish remarks in an American electrical journal published in Chicago; but the matter assumed a more important shape when, on Friday morning, we received the *Electrical World* of New York, dated August 18th, and found therein letters from Prof. Houston and Mr. Kennelly, Dr. Louis Duncan, and from Mr. F. W. Dunbar, together with an editorial comment.

Our esteemed contemporary, the *Electrical World*, takes the matter very seriously:—

"It is seldom that we find it necessary to disagree *in toto* with our esteemed London contemporary, *The Electrician*; but, notwithstanding the ability with which it has clung to its opinion as to the non-efficacy of the sine form of curves of alternating E.M.F., we have not been able to see anything but hopeless error in its views of this subject. In our issue of last week and elsewhere in the present issue several correspondents whose opinions have an authoritative value confirm the views we have expressed, and offer an accumulation of evidence, both theoretical and experimental, which should definitely settle the question. The very neat general mathematical demonstration of Mr. F. W. Dunbar complements the special deduction in Kennelly's Institute Paper on impedance, while the other letters bring to bear an accumulation of evidence that takes away every vestige of ground for the opinion which they contest. From both the theoretical and the practical standpoint it can be considered as definitely established that the sine form of curves of alternating E M.F. is the best, for the reasons that it involves less inductive drop and less iron losses in transformers, and is absolutely necessary in motor work to avoid deleterious reactions from the upper harmonics otherwise present. To these advantages may be added the further one recently referred to by us in commenting on some German experiment with alternating arcs, which is that for the practical working of such arcs the sine curve insures smoother operation of the mechanism and a minimum of noise.

Our readers may judge for themselves as to the advantages of sine curves for arc work from the German Paper, of which we print the first half in our present issue. We refer to this Paper elsewhere.

Our critics, in the majority of cases, have made two mistakes in regard to our statements as to the value of a sinusoidal electro-

Digitized by Google

motive force. Firstly, they have understood us to say that the sine curve is the *worst* possible for such a function; whereas, all that we did say was that it is a waste of time and skill to try to get a sine curve, because the sine curve is by no means the *best* possible. Secondly, they have failed to realise that our criticisms are of a perfectly general nature, relating to the inherent qualities of the various electromotive forces, and by no means referring to the performances of any one particular machine. It is true that we pinned our remarks upon some trials of alternate-current machinery by Dr. Duncan; but we merely did so in order to say that these trials by no means warranted the general conclusion that the sine function is the best. Reference to our Note, on page 319, will show this to be the case. It is quite possible that a certain motor might have such idiosyncracies as would lead it to work better with a sine function than with an electromotive force of any other form; indeed, Dr. Duncan seems to have discovered such a motor. He says:—

"As far as the matter in question is concerned, the statement of Mr. Scott, of the Westinghouse Company, made in the discussion of the Paper referred to, is very much to the point. He instanced the case of a two-phase motor, which, when driven from a certain dynamo, heated badly and had a great deal more 'armature slip' than was expected. It was found on investigation that the curve of dynamo E.M.F. was irregular, and the third harmonic was prominent. Being supplied with a sine E.M.F., the same motor ran efficiently and satisfactorily.' Nothing can be more direct than this evidence. Mr. Scott remarked that in such a motor the third harmonic tended to turn the armature in a direction opposite to the primary wave, the result being disastrous. Mr. Steinmetz, who champions the three-phase system, pointed out that the third harmonic would tend to revolve the armature of a three-phase motor in the proper direction. While this is true, the efficiency of this component would be small."

We shall refer to the third harmonic presently. As to the evidence, it is by no means direct; it only shows that one particular *non*-sine curve was worse than the sine curve, with one particular motor.

Our esteemed friends, Messrs. Houston and Kennelly, are at variance with us when we assert that this controversy is based upon the conclusions of mathematicians rather than of practical research. We quote from their letter:—

"It is asserted that the reasons which have induced American designers to endeavour to obtain a sinusoidal E.M.F. in their alternators are mathematical rather than practical. This is by no means the characteristic of American electrical engineers, who are confessedly pre-eminently practical. In point of fact, the reasons, so far from being of a mathematical nature, are solely practical. It is known by observation that the loss of energy in the excitation of transformers is greater for non-sinusoidal than for sinusoidal E.M.F.'s, especially at high frequencies. It is true that the extra loss of energy through non-sinusoidal E.M.F. waves is usually not of sufficient importance to render a strictly sinusoidal E.M.F. of great value for merely lighting purposes. But for purposes of power transmission, deviations from the sinusoidal form of E.M.F. wave become deleterious, partly on account of the additional drop or pressure in the conductors transmitting the energy, partly owing to the additional loss of energy entailed in the transformers, but principally owing to the reactions set up in the induction motors by the virtual harmonics present in the sinusoidal form of E.M.F. whenever rotary field motors are employed."

Nevertheless, it is to the mathematics of Mr. Kennelly that Dr. Duncan and other adherents to the sine curve have referred us in support of their theories. Messrs. Houston and Kennelly make the mistake already referred to, of supposing that we are placing the sine curve at the bottom of the list.

It is vagueness itself to speak of comparisons between sinusoidal and non-sinusoidal curves, without naming exactly the components of which these latter are composed. There are non-sinusoidal curves which are vastly worse than the sine curve, and there are other non-sinusoidal curves which are decidedly better than the sine curve. Take, for example, Dr. Duncan's sine function with the third harmonic. If the harmonic is exactly in anti-phase with the fundamental, a condition of things shown in Fig. 1 will occur. The illustration shows that, with three different amplitudes, three different resultant curves are produced, every one of which has a less maximum than the primary curve. If the maxima of the two components are co-phased, however, the condition of things represented in Fig. 2 will take place. The resultant maximum will be greater than the maximum of the primary. For other phase relations between the components, intermediate results would occur. Do our critics mean to say that the losses in an alternator, transformer, or motor would necessarily be greater with the flat-topped resultant curve in Fig. 1 than with the fundamental sine curve? Do they insist that to get the best results it is necessary to avoid the flattened curve, as well as the peaky

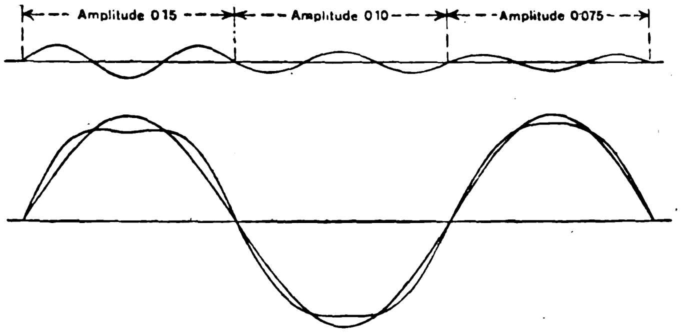

Fig. 1.—A Sine Curve compounded with its third harmonic, with maxima in anti-phase. Amplitude of harmonic, 0·15, 0·1, and 0·075. Amplitude of sine curve being unity.

curve (in Fig. 2), and to get as closely as possible to the simple sine curve? We will grant them that the peaky curve will not best satisfy their wants; but we must insist that the efficiency of the flat curve is better than either of the others. In this

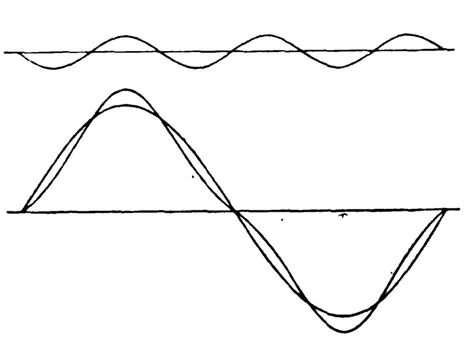

Fig. 2.—A Sine Curve compounded with its third harmonic with maxima in co-phase. Amplitude of harmonic, 0·15.

connection we would refer our critics to the letter from Mr. Steinmetz, which we published last week. Mr. Steinmetz says:—

"The hysteretic loss per cycle in the transformer exclusively depends upon the limiting values of magnetism, and will remain the same as long as these are the same. . . . If the wave of E.M.F. differs from sine shape, we can consider it as a fundamental sine wave with higher harmonics superimposed thereon, and then the wave of magnetism will also be a distorted wave, consisting of a fundamental sine wave superimposed by sine waves of triple, quintuple, &c., frequency. It is obvious now that if the triple harmonic wave of magnetism is superimposed upon the fundamental wave in such a way as not to increase its maximum value, the core loss will not be increased; but the amount of energy transformed is increased by the energy of the triple harmonic."

Finally, we would remark that since the flat-topped curve is the best for general distribution purposes, best for transformer and generator efficiency, and as good, at least, as any other for lighting purposes by glow lamps, and, if we understand Herrn Rössler and Wedding aright, better than a sine curve or a peaked curve for arc lamps, and it is therefore to the interest of makers to cultivate this type of curve. Herrn Rössler and Wedding, indeed, in the second part of their Paper, for which we cannot find space this week, say, "Apparently it would be best to build machines whose curves approach the shape of Fig. 15." This diagram, which we shall reproduce next week, is simply rectangular. That there are special cases where another type of curve is better adapted to the local conditions we are quite ready to believe; and we are also willing to recognise the existence of alternate-current plant which can only subsist on sine curves. But it remains yet to be shown that there is the smallest ground for believing the sine curve to be inherently the best and most efficient. This neither the able pen of Mr. Kennelly, nor the fallacies of Mr. F. W. Dunbar, nor the experiments of American electrical engineers, give any present indication of doing. While Dr. Louis Duncan goes to one extreme and considers the particular case of his peculiar and fastidious motor, Mr. Dunbar takes the

Digitized by Google

other extreme, and so anxious is he to generalise, that he abandons the consideration of the presence of iron, and bases his arguments on a mechanical analogy. The discussion of the behaviour of iron-less transformers and motors may be interesting to mathematicians, and of use to some kinds of students; but the whole point of *our* case is the effect on the iron. After recapitulating our remarks, Mr. Dunbar writes :—

"These criticisms, coming from the London *Electrician* and entirely unsupported by any theoretical or practical evidence, are even more astounding when we consider the ease with which it may be shown that the most efficient rate at which electrical force may be applied to do useful work is the sine curve, and this without the necessity of discussing *individually* the 'intricate phenomena of alternating-current machinery.'"

He then indulges in some "iron-less" mathematics, and naturally arrives at the conclusion that where simple mechanical considerations of mechanics are concerned, a succession of simple sine impulses is the best. Having proved this he goes on to say :—

"The sine curve of E.M.F., then, is the curve which will impart the greatest average momentum to an electrical circuit for a given average alternating force; that is, it is the 'best' curve for an alternating E.M.F. which is to be used to do useful work, for it is evident that all losses due to eddy currents, hysteresis, &c., &c., will then also be a minimum."

This conclusion is, we maintain, quite unwarranted.

Confidently as we maintain that a sine curve is not the best, and that a flat-topped curve is better, we must point out that the difference when reduced to £ s. d. is but a trifling amount. The experiments to which we have alluded agree well with those of Mr. Steinmetz, viz., that the iron losses in generator and transformer were about 10 per cent. greater with a sine curve than with a flat-topped curve. This flat-topped curve was not, so far as we are aware, designedly of that shape, and when the "best" curve has been obtained the difference will no doubt be greater. This week Mr. Steinmetz strengthens his former statements and our position by giving an example of a motor, in which the relative economy with the non-sinusoidal wave was as high as 13 per cent. His letter will be found in our correspondence columns. We do not, therefore, urge that the saving will be a large one. The matter is not one of vital importance; it is hardly worth having a demonstration in Hyde Park about it; but our original contention, that it is folly to struggle after a sine curve for general work, remains unshaken.

LIGHT RAILWAYS.*

The Times published not long ago some articles on the subject of light railways, giving a general account of the method in which the benefits of cheap railway transport had been extended to thinly-populated agricultural districts in foreign countries without the great expense of first construction and equipment that are involved in building such railways as our Board of Trade rules require. Some particulars of a line of this character, which may be regarded as typical, and which has been at work for two years successfully, have recently been given by *Le Génie Civil*, a French engineering journal.

The line referred to is in the department of Loiret, in France. Its termini are 22 kilometres apart, but in order to serve important properties the line was made 31 kilometres in length. The termini are Pithiviers and Toury, both of which are stations on existing railways. The district is one in which the cultivation of beetroot has recently made great progress, and in which sugar factories exist. The Conseil-Général (or, as we may say, County Council) of the department decided to construct the line out of their own funds, chiefly for the development of this industry, taking into consideration, also, the fact that, by transferring to a railway the heavier cart traffic, a good deal would be saved to them in road maintenance. This is a point to which the attention of our highway boards might well be directed in connection with projected lines in England of the same character.

The French authorities have studied, with characteristic minuteness, the methods by which railway construction can be encouraged by the State without invading the proper field of private enterprise, and, at the same time, without sacrificing to contractors and company promoters the legitimate profits which the State should expect from its railway investments when they are successful. In the present case the line was built by the department, and was leased for working to a company, tenders for the purpose having been invited. The terms were ingeniously devised, and, to English railway managers, would not seem to leave much profit to the lessee. In any year when the gross receipts per kilometre fall below 1,800fr. half the difference is paid by the department to the lessee; when the receipts are over 2,300fr. the lessee pays over half the excess; when they are between 1,800fr. and 2,300fr. he keeps what he makes without subsidy or rebate. These sums represent gross earnings respectively of about £2. 4s. 6d. and £2. 17s. per mile per week, which, according to our ideas, would not be remunerative even for a very light railway. The fact, however, that a responsible and experienced firm of contractors are working the line on these terms shows that a profit is to be made with a very small volume of traffic, if the system of working is adapted to the conditions.

The following description will show how far the line departs from what English practice at present permits. It is laid at one side of the highway, and is not separated in any way from the rest of the road reserved for cart and carriage traffic. To this extent it answers to what we call a steam tramway, but on the other hand it is laid with rails of the ordinary railway pattern, on steel cross sleepers, and ballasted. At crossings check rails are, of course, provided. The gauge is only two feet. The rails are flat-footed, and weigh only 19·1lb. per yard, which is now found to be a little light for engines of 12 tons weight; 24lb. per yard, it is said by the engineer of the line, would have been better and ample. The rails, in 16ft. lengths, are riveted to light steel sleepers, and, therefore, each section can be brought whole to its place, no work being left to be done on the ground except bolting up the fish-plates.

One great advantage of this narrow gauge and portable permanent way—an advantage which our British engineers have not, perhaps, considered—is the facility with which farmers and others can lay down a temporary siding or branch which can be moved about into any field or to any warehouse or barn where there may be a few train loads to pick up. With the line we are now considering this advantage has been largely realised.

No stations were built further than an open shed with a small office to hold a weighing machine and to lock up parcels. Tickets to passengers are issued on the train by the conductor. The passenger carriages are of the tramway type, and measure 31½ft. long by 6¼ft. wide, with three compartments for different classes in each carriage. The waggons are of the American bogie type, and carry 10 tons each. This line was built for £1,225 per mile, and cost £330 per mile additional for equipment, making a total outlay of £1,555 per mile. It appears to have worked safely and usefully, and to render nearly all the services to the district which a line costing £10,000 per mile could have rendered. Last year (the only complete year it has been in operation) it carried 27,235 passengers, and during the beetroot season, lasting two months, it carried over 15,000 tons of beetroot. As the crop of beetroot was a very poor one the traffic receipts were disappointing, and only amounted to 52,145fr. This being a little under the limit named above, the department had to pay a small compensation to the lessee. The results were sufficient to show that in ordinary years the department will receive an income from the line. It is well known that with all railways a few years are necessary for the normal traffic to develop, so that the department may fairly hope in a few years to receive 4 or 5 per cent. on the modest outlay they have made on construction. Meantime, indirectly, the population all benefit by the saving in cost of carriage and in the cost of keeping up the roads to a larger extent than they lose by the increase in rates or taxes to pay interest on the capital cost of the railway.

TO THE EDITOR OF THE TIMES.

SIR: The article in your issue of the 25th inst. on light railways in France leads me to mention that one of the latest measures of Lord Lansdowne's vice-royalty was the issue of provisional standards for such railways in India, on a gauge of 2½ft. These are intended primarily to be feeders to the main lines, and to be constructed in such a way as to enable them to be laid on the sides of existing roads; the restriction as to speed—viz., 12 miles an hour—and other limitations precluding any possibility of their competing seriously, if at all, with the existing lines.

The mileage of such lines in India is at present small; but so far they have done extremely well, and further extensions are in contemplation. Built as independent lines, their cost in India has been from £1,800 to £2,000 per mile: while, laid on existing roads, they can be constructed for about half this sum. The difficulty in India, as it would be, indeed, in England, is that most of the lines would be comparatively short and isolated, and thus, in order to ensure economy in working, it would be necessary either to group a certain number in a province (or in England in a county) under one company or administration, or to enter into arrangements for each being worked by the main lines they feed.—Yours, &c.,

HORACE BELL,
late Consulting Engineer for State Railways,
Oriental Club. Government of India.

The Electrician.

(The Oldest Electrical Journal, 1861–1878.)

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny

Editorial, Publishing, and Printing Offices:

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months. s. d.	6 months. s. d.	12 months. s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Other Countries	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

"THE ELECTRICIAN" *has more* ADVERTISERS *than any other British Electrical Journal—a convincing proof of its value as an Advertising Medium.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4.30 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of*—

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Price 12s. 6d., post free 13s.

STEEL-PLATE PORTRAITS

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; and Dr. Heinrich Hertz, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

THE MOLECULAR THEORY OF MAGNETISM.

To a somewhat meagre and exhausted audience in Section A at Oxford, thinned collectively by the protracted sitting of the Section and individually by the want of lunch, Mr. FRANCIS G. BAILY made a communication which in scientific importance may, without undue exaggeration, be said to rank as a good second to Lord RAYLEIGH's announcement of the "new gas." The great interest of his "Note on the Hysteresis of Iron and Steel in a Rotating Magnetic Field," an abstract of which is given in another column, lies in the fact that it supplies a most remarkable confirmation of Prof. EWING's well-known theory of the molecular process in magnetic induction. Hitherto the evidence in favour of that theory has consisted in its ability to give a rational account of the host of phenomena, often complicated and obscure, which have been found by experiment to characterise the process of magnetisation. Prof. EWING has shown that his theory accounts for the division of the process into three well-marked stages, that it explains residual magnetism and hysteresis and the dissipation of energy which hysteresis involves, that it accords with what is known about magnetic saturation, that it furnishes a key to the intricate group of results which have accrued from experiments on the effects of stress and temperature on the special properties of the magnetic family of metals, and that these results can, in fact, be reproduced with astonishing completeness in a model structure built up of little permanent magnets. Moreover, it is not too much to say that in all the great collection of facts we now possess about magnetism there is not one that can be cited as antagonistic to the molecular theory. To anyone who has followed closely the experimental work of Prof. EWING himself, of Dr. HOPKINSON, and of other recent contributors to the aggregate of knowledge in this large subject,

Digitized by Google

the cumulative evidence in favour of the theory is so strong as to carry conviction. But now an entirely new item of evidence has been supplied in the form of a verification, by experiment, of a result—otherwise improbable enough—which had been predicted as a consequence of the molecular theory.

To appreciate the point of Mr. BAILY's discovery we must hark back to the Leeds meeting of the British Association, when Prof. EWING first made his theory generally known, and exhibited his model of molecular magnets. The comment was then made, originally we believe by Mr. JAMES SWINBURNE in a descriptive article in *Industries*, that if the theory were sound it would lead to this conclusion, that a piece of iron or steel revolving like the armature of a dynamo in a very strong magnetic field should show no hysteresis, and consequently require no expenditure of work to maintain its rotation, provided, of course, that the effects of Foucault currents were eliminated. For when iron revolves in a magnetic field the hysteresis is due, according to the theory, to the breaking up of molecular engagements and to the formation of fresh ones. The molecules dissipate energy in vibrations as they fall violently into new groups. This can happen only when the field is not excessively strong, for, given a sufficiently strong field, every molecule will be held oriented in a single definite direction while the piece turns, just as the wire bobbins of a cable-winding machine remain parallel to themselves during the revolution of the frame that carries them ; and hence in the revolving iron there will, with a powerful field, be no dissipation of energy because there is no opportunity for the making and breaking of molecular ties with unstable movements of the molecules. This conclusion, so remarkable in itself and so apparently opposed to experience, was in fact adduced by Mr. SWINBURNE as an argument against the acceptance of the molecular theory. But it was clear that experience was too imperfect to be properly appealed to. According to the theory itself the work lost through hysteresis in a rotating armature should at first increase as the field is strengthened, and should not begin to diminish until a sufficiently strong value is reached to bring about a close approach to magnetic saturation. It was easy to believe that in dynamo armatures, and in other cases where hysteresis was known to play an important part, the field was insufficient to hold the molecules from swerving into dissipative courses and squandering their energy in a wild succession of temporary alliances. Experiment only could show whether a stronger directing field would preserve them from this giddy whirl of exhausting entanglements; and Prof. EWING, in his book on Magnetic Induction, published in our columns, refers to the matter as one well worthy of experimental examination from this point of view. In the discussion of Mr. BAILY's Paper he mentioned, indeed, that he was engaged for some time, along with Mr. WILBERFORCE in looking for the effect in question, but the experiments were temporarily discontinued without having been brought to a conclusive issue.

Meanwhile, Mr. BAILY has attacked the matter with complete success, and has obtained a result which is in every respect in agreement with the anticipations to which the molecular theory has led. By measuring the torque which is required to hold a small armature from revolving when the field magnet is slowly turned, he has measured the expenditure of work which would be necessary if the armature were made to turn in a fixed field. He has examined this for various strengths of the field, from weak beginnings up to values greatly exceeding those used in dynamo practice, and sufficient to bring the molecules of the armature nearly to the perfect alignment which corresponds to saturation. Starting with a weak field, he finds that the work spent in turning the iron at first increases but slowly as the field is increased, but presently a stage is reached when the expenditure grows at a vastly more rapid rate. The first stage corresponds, in the molecular theory, with that in which the molecules turn for the most part with the iron, only becoming slightly deflected to one side or the other of their normal direction in the group, in a quasi-elastic manner, in response to the varying direction of the external field. The initial molecular grouping is not seriously interfered with during the rotation of the piece. As the strength of the field augments, however, more and more of the molecules suffer deflection beyond their stable range, and a marked increase is observed in the rate at which the torque grows with increasing magnetic force. Ultimately, however, with still stronger fields, the tendency to form new groups is checked, the torque, therefore, passes a sharply defined maximum, and descends rapidly to zero, or to something closely approaching zero, as the condition of saturation is reached. Mr. BAILY finds that the same general result is exhibited by both iron and steel. In the early stages the dissipation of energy in a revolving field has the same order of magnitude as that which occurs when the field is reversed in sign without rotation ; in the later stages the effects of the two processes are widely different—the energy expended in reversal of the field goes on increasing ; but the energy expended in rotation of the field falls off, and finally approximates to zero. It is safe to say that such a result as this would never have been anticipated except in the light of the molecular theory. That it should have been found after prediction from the theory furnishes the most convincing support which the theory could possibly have received. We may adapt the language which Lord SALISBURY used in his introductory address regarding the finding of new elements after their existence had been predicted from the Periodic Law, and say that this remarkable confirmation has left Prof. EWING's molecular theory of magnetic induction in an unassailable position.

Its relation to the molecular theory gives the chief interest to Mr. BAILY's discovery ; but it may prove to be not without importance on the practical side. It is at least a matter for dynamo builders to consider whether the drawbacks incidental to a very strong armature induction are greater than the advantage which would accrue from eliminating hysteresis losses in the armature core. And other uses may in time be found for a method of treating iron which allows its magnetism to be reversed without expenditure of work. Be this as it may, there can be no question as to the immense theoretical value of Mr. BAILY's experiment. We join heartily in the chorus of congratulation which was raised by such of the attenuated and famished remnant of the Section as were able to appreciate the bearing of his result. The experiment at once takes its place with a select few which form landmarks in magnetic investigation. One may safely prophesy that it will long be cited as an event in the history of the science.

REVIEWS.

English Patent Practice. By HENRY CUNYNGHAME. (London : W. Clowes and Sons. 1894.)

Books upon Patent Law are of two kinds. The one, generally consisting of bulky volumes, is intended for lawyers, and the other for patentees, manufacturers, and others who have to do with patents. The latter class are, as a rule, of moderate size, and no clear line can be drawn between a legitimate work on the subject and a mere touting pamphlet issued by an advertising patent agent. Where no statement is made on the title page or in the preface of the aim of a book on Patent

Digitized by Google

Law, a glance through its pages will show whether it is a mere dry law book, or whether it is written for the general public. But the volume before us, though severely compressed in arrangement and condensed in style and addressed to the legal profession, is not only of great value to lawyers, but may for the most part be read with interest and profit by those who are concerned with patents for their own inventions or otherwise. To electrical engineers particularly this book will prove attractive, for the author's intimate acquaintance with electrical science and its applications have led him to draw largely on electrical cases for examples. The Harrison, Bassano, and other telephone cases, Lane Fox *v.* Kensington Co., Edison *v.* Woodhouse, Edison *v.* Holland, the Brush compound winding cases, British Tanning Co. *v.* Groth, Goulard and Gibbs revocation, are cited, besides such older and well-known cases as The Electric Telegraph Co. *v.* Brett. One feature, which we believe to be unique, adds greatly to the lucidity of the examples, and renders the book peculiarly interesting and readable; this is the use of a large number of extremely simple sketches and diagrams. The three-wire case is, of course, easily explained with this aid, and thoroughly too, for five diagrams are given. Penn's propeller bearing is another example of the simplest possible diagram. The Plimpton skate, which is so often heard of in patent cases, and which is by no means easy to describe in words, is well explained by means of three sketches.

The most valuable feature of this work to the professional man is the arrangement of its contents. Sectional headings are used to distinguish the various rules of law, which are for the most part stated in the form of propositions. The opening chapters after a historical introduction, deal with Subject matter, Utility, Novelty, Success, Anticipation, the next five discuss the specification under the heads, Title, Provisional, Complete, Claims, and Drawings. A highly technical chapter relates to Construction. Then follow chapters on Amendment, Patentees and Procedure. Infringement is studied at considerable length, and, in a chapter on Action of Infringement, very practical information is given as to "particulars of breaches" and "particulars of objections." Besides a full table of contents and table of cases, a very complete index is given. The Statutes, Acts, rules and official forms are to be found in an appendix. The preface is not the least interesting part of the book, and it concludes with the following hint to inventors:—

"The words of Sir Hugh Platt in 1589 are as true now as they were when he wrote them: 'I have always found it in mine own experience an easier matter to devise manie and profitable inventions, than to dispose of one of them to the good of the author.'"

NOTE ON THE HYSTERESIS OF IRON AND STEEL IN A ROTATING MAGNETIC FIELD.*

BY F. G. BAILY.

It has long been known that, up to the limits of experiment, the value of hysteresis in an alternating magnetic field increases continuously. But it is a deduction from Prof. Ewing's molecular theory of magnetism that in a rotating magnetic field the hysteresis should diminish at a high induction, or at least show a reduction in the rate of increase. The following experiment substantiates this deduction in a very complete manner:—An electromagnet is rotated on bearings concentric with the bore of its own pole-pieces, which were bored out cylindrically. In the polar cavity a finely-laminated armature is suspended between centres, and held by a spiral spring attached to the axle and to a fixed support. Movement of the armature is indicated by a beam of light reflected from a mirror on it. On rotating the magnet, the armature tends to rotate with it by reason of hysteresis. The motion is checked by the spring, and the consequent deflection is proportional to the instantaneous value of the hysteresis per revolution. The curve of hysteresis and induction obtained commences like that in an alternating field, rising very slowly at first, then more rapidly, but finally reaching a maximum and bending over. The fall is very rapid so far as the experiments have been tried, shows no sign of becoming asymptotic, but runs straight towards the zero line. Soft iron and hard steel give the same results, the differences between them corresponding to their differences in the B/H curve. The three states of molecular arrangement, which are the essential point of the molecular theory, are exactly reproduced in the hysteresis curve. This first stage of quasi-elastic movement gives a very small hysteresis value. The second stage of irregular molecular groups and magnetic combinations gives a value approximately proportional to the induction at a steep inclination; this extends to the knee of the B/H curve. The third stage of approaching saturation gives a rapidly diminishing hysteresis when the molecular magnets are ranged in regular order along lines of force, and new combinations and irregular movements are prevented. Since the non-appearance of a correspondence between the B/H curve and the hysteresis curve in alternating fields has been urged as an argument against the molecular theory of magnetism, this complete accord and verification of the deduction previously made is important as giving powerful support to Prof. Ewing's theory.

* Mr. Baily intends to publish a more complete Paper on this subject, and does not wish to publish his recent communication to Section A of the British Association in full. This abstract is reprinted from *Nature.*

ALTERNATE CURRENT RESONANCE.

BY ERNEST WILSON.

The present short research constitutes an experimental verification of one or two familiar problems in the theory of alternate currents. The following is an extract from a paper by Dr. Hopkinson "On the Theory of Alternating Currents," read at the Institution of Electrical Engineers, November 13, 1884, to which reference will be made:—

"Some time ago Dr. Muirhead told me that he had observed that the effect of an alternate-current machine could be increased by connecting it to a condenser. This is not difficult to explain: It is a case of resonance analagous to those which are so familiar in the theory of sound and in many other branches of physics.

"Take the simplest case, though some others are almost as easy to treat. Imagine an alternate-current machine with its terminals connected to a condenser; it is required to find the amplitude of oscillation of potential between the two sides of the condenser. Let R γ be the resistance and self-induction of the machine, $E \sin \frac{2\pi t}{T}$ its electromotive force, C the capacity of the condenser, V the difference of potential sought, and x the current in the machine, then

$$C \dot{V} = x$$

and

$$\gamma \dot{x} + R x = E \sin \frac{2\pi t}{T} - V;$$

whence

$$\gamma \ddot{x} + R \dot{x} = \frac{2\pi}{T} E \cos \frac{2\pi t}{T} - \frac{x}{C}$$

$$x = \frac{\left\{1 - C\gamma\left(\frac{2\pi}{T}\right)^2\right\}\cos\frac{2\pi t}{T} + RC\frac{2\pi}{T}\sin\frac{2\pi t}{T}}{\left\{1 - C\gamma\left(\frac{2\pi}{T}\right)^2\right\}^2 + R^2C^2\left(\frac{2\pi}{T}\right)^2} \cdot \frac{2\pi E C}{T}$$

$$V = \frac{\left\{1 - C\gamma\left(\frac{2\pi}{T}\right)^2\right\}\sin\frac{2\pi t}{T} - RC\frac{2\pi}{T}\cos\frac{2\pi t}{T}}{\left\{1 - C\gamma\left(\frac{2\pi}{T}\right)^2\right\}^2 + R^2C^2\left(\frac{2\pi}{T}\right)^2} \cdot E \quad . \quad (1)$$

Amplitude of V is therefore

$$= \frac{1}{\sqrt{\left\{1 - C\gamma\left(\frac{2\pi}{T}\right)^2\right\}^2 + R^2C^2\left(\frac{2\pi}{T}\right)^2}} \cdot E \quad . \quad (2)$$

"Now suppose E = 100 volts, the machine would light up an incandescent lamp of about 69 volts; let $T = \frac{1}{200}$ second, C = 100 microfarads, and $\frac{2\pi\gamma}{T} = 8$ ohms, and $R = \frac{1}{10}$ ohm, all figures which could be practically realised, we have amplitude

Digitized by Google

of $V = 80\,E$ roughly, or the apparent electromotive force would be increased eighty-fold."*

Part I.—Equation (1) in the above quotation shows that according as $C\gamma\left(\frac{2\pi}{T}\right)^2$ is greater or less than unity, so will the phase of V be retarded or accelerated. Equation (2) shows that when $C\gamma\left(\frac{2\pi}{T}\right)^2$ is unity the amplitude of V is a maximum for variation of γ.

A Siemens W 12 alternate-current machine A (Fig. 1) was connected in series with a Westinghouse transformer, B, having a closed magnetic circuit, and a condenser, C. The alternator

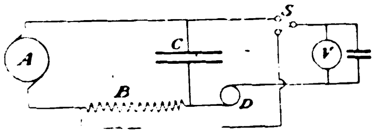

Fig. 1.

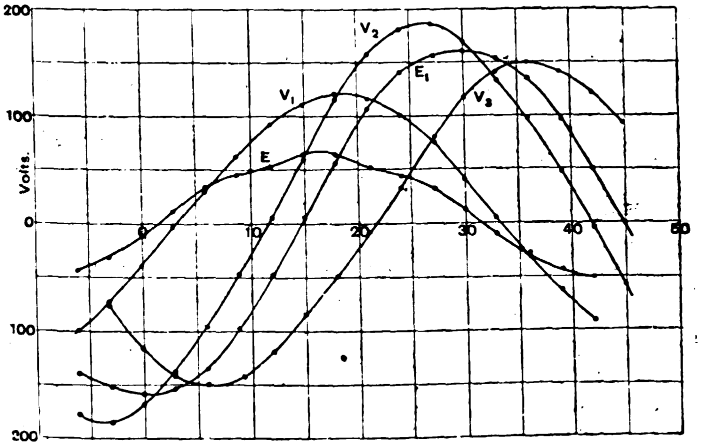
was excited with a current of 10 amperes, and gave an open circuit, at a frequency of 95·5 periods per second, a maximum electromotive force, E, of 66 volts. This is the curve E in Fig. 2.

The capacity of C was made 1 microfarad, and the frequency 88, the excitation of the alternator being kept constant at 10 amperes. V_1 (Fig. 2) is the curve of potential then taken across the terminals of the condenser by means of a revolving contact-maker, D, fixed to the shaft of the alternator, and the Kelvin multicellular voltmeter V. The frequency was increased until the amplitude of V was a maximum which occurred at 95·5. V_2 is the curve then taken across the condenser. The frequency was further increased to 118 and the curve V_3 observed.



As predicted by theory, the phase of V is retarded or accelerated with regard to its position at frequency 95·5, accompanied in either case by a diminution of amplitude.

In order to show that $C\gamma\left(\frac{2\pi}{T}\right)^2$ is approximately unity when the maximum amplitude of V is observed; the frequency being 95·5, the curve of potential across the terminals of the transformer was observed simultaneously with V_2. This was readily done by means of the two-way switch S. E_1 is the curve so obtained. In curve V_2 we see that V changes 120 volts, whilst time changes ·00117 second, therefore, the maximum current $x = \cdot 1$ ampere. We have also maximum amplitude of curve E_1 160 volts.

Then $\frac{2\pi\gamma}{T}$ = approximately 1,600 ohms;

therefore $C\gamma\left(\frac{2\pi}{T}\right)^2 = \cdot 96$ as against unity.

From curve V_2 we have also amplitude 185 volts.

$$185 = \frac{1}{RC\frac{2\pi}{T}}\,66$$

$$R = 595 \text{ ohms.}$$

* The reader is referred to Prof. J. A. Fleming's work on the Alternate Current Transformer for a full discussion of this subject.

The ohmic resistance of the circuit of the alternator and Westinghouse transformer is about 6 ohms, but there is the further dissipation of energy by magnetic hysteresis and eddy currents.

From previous experiments upon this transformer, the rate at which energy is being dissipated on open circuit for the whole core is about 80 watts, with a frequency of 98, and a maximum current of 0·3 ampere in the primary. We have already found that in the present case the maximum current $x = 0{\cdot}1$ ampere. Therefore,

$$\{\sqrt{\text{mean}^2\,x}\}^2\,R = \text{about 3 watts.}$$

Experiments have not been made to find the rate of dissipation of energy in this transformer with a maximum current of 0·1 ampere at a frequency of 95; but an examination of Prof. Ewing's experiments* on soft iron for transformer cores shows that 3 watts is not far wrong.

It should be noted that with constant excitation, E increases with a decrease of T, and γ is a variable, since it is a function of x.

Part II.—The curve E (Fig. 2) is not a simple sine curve. It is well known that if E be any function of t, periodic or not, it can be expressed in the form

$$E = A_1\cos\frac{2\pi t}{T} + B_1\sin\frac{2\pi t}{T} + A_2\cos\frac{4\pi t}{T} + B_2\sin\frac{4\pi t}{T}$$
$$+ \ . \ . \ . + A_r\cos\frac{2r\pi t}{T} + B_r\sin\frac{2r\pi t}{T} + \ . \ . \ . \ .$$

Let E be a periodic function of t which vanishes when $t = 0$, T, 2 T, . . . &c., and suppose the curve for E to be divided symmetrically by the axis of x; then E must change sign with t, and there must be no cosines.

$$\therefore\ E = B_1\sin\frac{2\pi t}{T} + B_2\sin\frac{4\pi t}{T} + \ . \ . \ . + B_r\sin\frac{2r\pi t}{T} + \ . \ . \ .$$

Next suppose, that in any half period the ascending curve is exactly similar to the descending portion, then increasing t by $\frac{T}{2}$ must merely alter the sign of E. Hence the even terms do not change sign when t is increased by $\frac{T}{2}$. Therefore, to satisfy the assumed condition, their coefficients must all vanish; that is to say $B_2 = 0$, $B_4 = 0$, &c.

$$\therefore\ E = B_1\sin\frac{2\pi t}{T} + B_3\sin\frac{6\pi t}{T} + \ . \ . \ .$$

Let

$$E = B_1\sin\frac{2\pi t}{T} + B_2\sin\frac{4\pi t}{T} + \ . \ . \ . + B_r\sin\frac{2r\pi t}{T} + \ . \ . \ .$$

Required to determine the coefficients B_1 . . . B_r . . . when E is known. Multiply each side of the equation by $\sin\frac{2r\pi t}{T}$ and integrate between the limits $t = 0$ and $t = \frac{T}{2}$; that is, over a half period.

$$\therefore \int_0^{\frac{T}{2}} E\sin\frac{2r\pi t}{T}\,dt = \int_0^{\frac{T}{2}} dt\,\sin\frac{2r\pi t}{T}\left\{B_1\sin\frac{2\pi t}{T} + \ . \ . \ . + B_s\sin\frac{2s\pi t}{T} + \ . \ . \ .\right\}$$

$$\text{Now}\int_0^{\frac{T}{2}} dt\,\sin\frac{2r\pi t}{T}\sin\frac{2s\pi t}{T} = \tfrac{1}{2}\int_0^{\frac{T}{2}}\left\{\cos\frac{2\pi(r-s)t}{T} - \cos\frac{2\pi(r+s)}{T}\right\}t\,dt$$

$$= \tfrac{1}{2}\left[\frac{T}{2\pi(r-s)}\sin\frac{2\pi(r-s)t}{T} - \frac{T}{2\pi(r+s)}\sin\frac{2\pi(r+s)t}{T}\right]_0^{\frac{T}{2}} = 0$$

This is true when r and s are different. When $r = s$

$$\int_0^{\frac{T}{2}} \sin^2\frac{2r\pi t}{T}\,dt = \tfrac{1}{2}\int_0^{\frac{T}{2}}\left\{1 - \cos\frac{4r\pi t}{T}\right\}dt$$

$$= \tfrac{1}{2}\left[t - \frac{T}{4r\pi}\sin\frac{4r\pi t}{T}\right]_0^{\frac{T}{2}} = \frac{T}{4}$$

Table I.

E.	$r=1.$ $B_1=216{\cdot}1.$			$r=3.$ $B_3=0{\cdot}76.$			$r=5.$ $B_5=12{\cdot}6$			$r=7.$ $B_7=-2{\cdot}6.$			$r=9.$ $B_9=0{\cdot}52.$		
	$\alpha=\frac{2\pi}{20}.$	Sin α.	E sin α.	3α.	Sin 3α.	E sin 3α.	5α.	Sin 5α.	E sin 5α.	7α.	Sin 7α.	E sin 7α.	9α.	Sin 9α.	E sin 9α.
78	18°	0·309	+ 24·1	54°	0·809	+ 63·1	90°	1	+ 78	54°	0·809	+ 63·1	18°	0·309	+ 24·1
130	36°	0·588	+ 76·4	72°	0·951	+123·6	180°	0	0	− 72°	− 0·951	− 123·6	− 36°	− 0·588	− 76·4
162	54°	0·809	+131·1	18°	0·309	+ 50·1	− 90°	−1	−162	18°	0·309	+ 50·1	54°	0·809	+131·1
203	72°	0·951	+193·0	− 36°	− 0·588	− 119·4	0°	0	0	36°	0·588	+119·4	− 72°	0·951	− 193·0
115½	90°	1·00	+115·6	− 90°	− 1	− 115·5	90°	1	+115·5	90°	− 1	− 115·5	90°	1	+115·5
			540·1			1·9			31·5			− 6·5			1·3

Thus all terms but the rth vanish, and we have—

$$\int_0^{\frac{T}{2}} E\sin\frac{2r\pi t}{T}\,dt = B_r \times \frac{T}{4};$$

$$\therefore\quad B_r = \frac{4}{T}\int_0^{\frac{T}{2}} E\sin\frac{2r\pi t}{T}\,dt.$$

If the half period $\frac{T}{2}$ be divided into ten equal parts, and the value of E determined by observation for each of these intervals, we have:

$$\int_0^{\frac{T}{2}} E\sin\frac{2r\pi t}{T}\,dt = \frac{T}{2}\times\frac{1}{10}\Sigma E\sin\frac{2r\pi t}{T},\text{ nearly.}$$

$$\therefore\quad B_r = \frac{1}{5}\Sigma E\sin\frac{2r\pi t}{T}.$$

In $\Sigma E\sin\frac{2r\pi t}{T}$, E must be observed for values of t equal to $0, \frac{1}{10}\frac{T}{2}, \frac{2}{10}\frac{T}{2}, \frac{3}{10}\frac{T}{2}, \ldots \frac{9}{10}\frac{T}{2}$, and the results multiplied by $\sin\frac{2r\pi t}{T}$ added together.

Table I. gives the coefficients B_1, B_3, B_5, B_7, B_9 so found; and it will be observed that B_5 is important, being about 6 per cent. of B_1. If, therefore, the machine be run at constant speed, and the capacity C varied, one might expect that when C is made $\frac{1}{25}$th, this harmonic would show itself as a rise on the curve showing the relation between V and the capacity. The curve in Fig. 3 is obtained by running the alternator at a

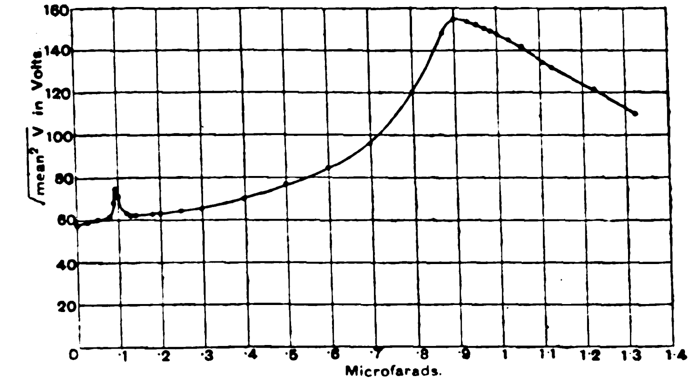

Fig. 3.

frequency of 95, gradually varying the capacity from O upwards, and observing V on the electrostatic voltmeter. We see that at 0·9 microfarad we have the maximum effect, which is what we have already observed in Fig. 2. Further, for 0·1 microfarad we have a rise on the curve. 0·1 is not a $\frac{1}{25}$th of ·9, but γ is a function of the current x which is reduced since the capacity is small, and this makes the resonance for the 5th harmonic occur at a greater value for C than $\frac{1}{25}$th—namely, $\frac{1}{9}$th. We see further from the equation that the curve in Fig. 3 would eventually reach the horizontal axis, and this would occur when $C=\infty$.

Mr. C. J. Evans, student demonstrator in the Siemens' laboratory, King's College, London, has assisted me in these experiments, and my best thanks are due to him.

THE IMPERIAL OHM, AMPERE, AND VOLT.

*At the Court at Osborne House, Isle of Wight, the 23rd day of August, 1894.

Present, the Queen's Most Excellent Majesty in Council.

Whereas by "The Weights and Measures Act, 1889," it is among other things enacted that the Board of Trade shall from time to time cause such new denominations of standards for the measurement of electricity as appear to them to be required for use in trade to be made and duly verified.

And whereas it has been made to appear to the Board of Trade that new denominations of standards are required for use in trade based upon the following units of electrical measurement, viz.:—

1. The Ohm, which has the value 10^9 in terms of the centimetre and the second of time and is represented by the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice 14·4521 grammes in mass of a constant cross sectional area, and of a length of 106·3 centimetres.

2. The Ampere, which has the value $\frac{1}{10}$ in terms of the centimetre, the gramme and the second of time and which is represented by the unvarying electric current which when passed through a solution of nitrate of silver in water in accordance with the specification appended hereto and marked A deposits silver at the rate of 0·001118 of a gramme per second.

3. The Volt which has the value 10^8 in terms of the centimetre the gramme and the second of time, being the electrical pressure that if steadily applied to a conductor whose resistance is one ohm will produce a current of one ampere, and which is represented by 0·6974 ($\frac{1000}{1434}$) of the electrical pressure at a temperature of 15°C. between the poles of the voltaic cell, known as Clark's cell, set up in accordance with the specification appended hereto, and marked B.

And whereas they have caused the said new denominations of standards to be made and duly verified.

Now, therefore, Her Majesty, by virtue of the power vested in Her by the said Act, by and with the advice of Her Privy Council, is pleased to approve the several denominations of standards set forth in the schedule hereto as new denominations of standards for electrical measurement.

C. L. Peel.

SCHEDULE.

I.—Standard of Electrical Resistance.

A standard of electrical resistance denominated one ohm being the resistance between the copper terminals of the instrument marked "Board of Trade Ohm Standard Verified 1894" to the passage of an unvarying electrical current when the coil of insulated wire forming part of the aforesaid instrument and connected to the aforesaid terminals is in all parts at a temperature of 15·4C.

II.—Standard of Electrical Current.

A standard of electrical current denominated one ampere being the current which is passing in and through the coils of wire forming part of the instrument marked "Board of Trade Ampere Standard Verified 1894" when on reversing the current in the

* From the *London Gazette* of Friday, August 24, 1894.

fixed coils the change in the forces acting upon the suspended coil in its sighted position is exactly balanced by the force exerted by gravity in Westminster upon the iridio-platinum weight marked A and forming part of the said instrument.

III.—Standard of Electrical Pressure.

A standard of electrical pressure denominated one volt being one hundredth part of the pressure which when applied between the terminals forming part of the instrument marked "Board of Trade Volt Standard Verified 1894," causes that rotation of the suspended portion of the instrument which is exactly measured by the coincidence of the sighting wire with the image of the fiducial mark A before and after application of the pressure and with that of the fiducial mark B during the application of the pressure, these images being produced by the suspended mirror and observed by means of the eyepiece.

In the use of the above standards the limits of accuracy attainable are as follows:—

For the ohm, within one-hundredth part of 1 per cent.

For the ampere, within one-tenth part of 1 per cent.

For the volt, within one-tenth part of 1 per cent.

The coils and instruments referred to in this schedule are deposited at the Board of Trade Standardising Laboratory, 8, Richmond-terrace, Whitehall, London.

Specifications referred to in the foregoing Order in Council:—

SPECIFICATION A.

In the following specification the term silver voltameter means the arrangement of apparatus by means of which an electric current is passed through a solution of nitrate of silver in water. The silver voltameter measures the total electrical quantity which has passed during the time of the experiment, and by noting this time the time average of the current, or if the current has been kept constant, the current itself can be deduced.

In employing the silver voltameter to measure currents of about one ampere the following arrangements should be adopted. The cathode on which the silver is to be deposited should take the form of a platinum bowl not less than 10cm. in diameter, and from 4cm. to 5cm. in depth.

The anode should be a plate of pure silver some 30 sq. cm. in area and 2mm. or 3mm. in thickness.

This is supported horizontally in the liquid near the top of the solution by a platinum wire passed through holes in the plate at opposite corners. To prevent the disintegrated silver which is formed on the anode from falling on to the cathode, the anode should be wrapped round with pure filter paper, secured at the back with sealing wax.

The liquid should consist of a neutral solution of pure silver nitrate, containing about 15 parts by weight of the nitrate to 85 parts of water.

The resistance of the voltameter changes somewhat as the current passes. To prevent these changes having too great an effect on the current, some resistance besides that of the voltameter should be inserted in the circuit. The total metallic resistance of the circuit should not be less than 10 ohms.

Method of making a Measurement.

The platinum bowl is washed with nitric acid and distilled water, dried by heat and then left to cool in a desiccator. When thoroughly dry it is weighed carefully.

It is nearly filled with the solution, and connected to the rest of the circuit by being placed on a clean copper support to which a binding screw is attached. This copper support must be insulated.

The anode is then immersed in the solution so as to be well covered by it and supported in that position; the connections to the rest of the circuit are made.

Contact is made at the key, noting the time of contact. The current is allowed to pass for not less than half-an-hour, and the time at which contact is broken is observed. Care must be taken that the clock used is keeping correct time during this interval.

The solution is now removed from the bowl, and the deposit is washed with distilled water and left to soak for at least six hours. It is then rinsed successively with distilled water and absolute alcohol and dried in a hot-air bath at a temperature of about 160°C. After cooling in a desiccator it is weighed again. The gain in weight gives the silver deposited.

To find the current in amperes, this weight, expressed in grammes, must be divided by the number of seconds during which the current has been passed, and by 0·001118.

The result will be the time-average of the current, if during the interval the current has varied.

In determining by this method the constant of an instrument the current should be kept as nearly constant as possible, and the readings of the instrument observed at frequent intervals of time. These observations give a curve from which the reading corresponding to the mean current (time-average of the current), can be found. The current, as calculated by the voltameter, corresponds to this reading.

SPECIFICATION B.

On the Preparation of the Clark Cell.

Definition of the Cell.

The cell consists of zinc or an amalgam of zinc with mercury and of mercury in a neutral saturated solution of zinc sulphate and mercurous sulphate in water, prepared with mercurous sulphate in excess.

Preparation of the Materials.

1. *The Mercury.*—To secure purity it should be first treated with acid in the usual manner, and subsequently distilled in vacuo.

2. *The Zinc.*—Take a portion of a rod of pure redistilled zinc, solder to one end a piece of copper wire, clean the whole with glass paper or a steel burnisher, carefully removing any loose pieces of the zinc. Just before making up the cell dip the zinc into dilute sulphuric acid, wash with distilled water, and dry with a clean cloth or filter paper.

3. *The Mercurous Sulphate.*—Take mercurous sulphate, purchased as pure, mix with it a small quantity of pure mercury, and wash the whole thoroughly with cold distilled water by agitation in a bottle; drain off the water, and repeat the process at least twice. After the last washing, drain off as much of the water as possible.

4. *The Zinc Sulphate Solution.*—Prepare a *neutral* saturated solution of pure ("pure recrystalised") zinc sulphate by mixing in a flask distilled water with nearly twice its weight of crystals of pure zinc sulphate, and adding zinc oxide in the proportion of about 2 per cent. by weight of the zinc sulphate crystals to neutralise any free acid. The crystals should be dissolved with the aid of gentle heat, but the temperature to which the solution is raised should not exceed 30°C. Mercurous sulphate treated as described in 3 should be added in the proportion of about 12 per cent. by weight of the zinc sulphate crystals to neutralise any free zinc oxide remaining, and the solution filtered, while still warm, into a stock bottle. Crystals should form as it cools.

5. *The Mercurous Sulphate and Zinc Sulphate Paste.*—Mix the washed mercurous sulphate with the zinc sulphate solution, adding sufficient crystals of zinc sulphate from the stock bottle to insure saturation, and a small quantity of pure mercury. Shake these up well together to form a paste of the consistence of cream. Heat the paste, but not above a temperature of 30°C. Keep the paste for an hour at this temperature, agitating it from time to time, then allow it to cool; continue to shake it occasionally while it is cooling. Crystals of zinc sulphate should then be distinctly visible, and should be distributed throughout the mass; if this is not the case add more crystals from the stock bottle, and repeat the whole process.

This method insures the formation of a saturated solution of zinc and mercurous sulphates in water.

To set up the Cell.

The cell may conveniently be set up in a small test tube of about 2cm. diameter and 4cm. or 5cm. deep. Place the mercury in the bottom of this tube, filling it to a depth of say 0·5cm. Cut a cork about 0·5cm. thick to fit the tube; at one side of the cork bore a hole through which the zinc rod can pass tightly; at the other side bore another hole for the glass tube which covers the platinum wire; at the edge of the cork cut a nick through which the air can pass when the cork is pushed into the tube. Wash the cork thoroughly with warm water, and leave it to soak in water for some hours before use. Pass the zinc rod about 1cm. through the cork.

Contact is made with the mercury by means of a platinum wire about No. 22 gauge. This is protected from contact with the other materials of the cell by being sealed into a glass tube. The ends of the wire project from the ends of the tube; one end forms the terminal, the other end and a portion of the glass tube dip into the mercury.

Clean the glass tube and platinum wire carefully, then heat the exposed end of the platinum red hot, and insert it in the mercury in the test tube, taking care that the whole of the exposed platinum is covered.

Shake up the paste and introduce it without contact with the upper part of the walls of the test tube, filling the tube above the mercury to a depth of rather more than 1cm.

Then insert the cork and zinc rod, passing the glass tube through the hole prepared for it. Push the cork gently down until its lower surface is nearly in contact with the liquid. The air will thus be nearly all expelled, and the cell should be left in this condition for at least 24 hours before sealing, which should be done as follows:—

Melt some marine glue until it is fluid enough to pour by its own weight, and pour it into the test-tube above the cork, using sufficient to cover completely the zinc and soldering. The glass tube containing the platinum wire should project some way above the top of the marine glue.

The cell may be sealed in a more permanent manner by coating the marine glue, when it is set, with a solution of sodium silicate, and leaving it to harden.

Digitized by Google

The cell thus set up may be mounted in any desirable manner. It is convenient to arrange the mounting so that the cell may be immersed in a water bath up to the level of, say, the upper surface of the cork. Its temperature can then be determined more accurately than is possible when the cell is in air.

In using the cell sudden variations of temperature should as far as possible be avoided.

The form of the vessel containing the cell may be varied. In the H form, the zinc is replaced by an amalgam of 10 parts by weight of zinc to 90 of mercury. The other materials should be prepared as already described. Contact is made with the amalgam in one leg of the cell, and with the mercury in the other, by means of platinum wires sealed through the glass.

THE LIVERPOOL OVERHEAD RAILWAY.*

BY JAMES HENRY GREATHEAD AND FRANCIS FOX, MM. INST. C.E.

(*Continued from page 494.*)

Permanent Way.—The permanent way consists of flat-bottomed steel rails, weighing 56lb. per yard, fixed on longitudinal timbers which are held down to the floor by iron lugs rivetted on to it, and oak keys. On the curves these timbers vary in thickness according to the necessary super-elevation of rail. The rails are fixed by spikes and fang-bolts, special care being taken in fixing them to avoid metallic contact with the main structure. The electrical conductor, which consists of a steel bar 4 sq. in. in section, of ⊓ form, is placed midway between the rails of each line, and is carried on porcelain insulators supported by cross timbers. The joints are provided with copper connections, and since the return current is brought back through the rails, a bent iron bond rivetted through the web of the rails is fixed at each fish-joint. Cables laid under ground from the railway to the generating station, a distance of 60 yards, connect the conductors and the rails with the dynamos.

Traction and Rolling Stock.—Running as the railway does through the entire length of the dock estate, from which steam locomotives have always been excluded, it was considered desirable that the use of such locomotives should, if possible, be avoided on the railway. Added to this consideration, the successful working of the City and South London Railway for some months pointed to the suitability of electricity as a motive power for such a service of trains as was contemplated on the Overhead Railway. Some additional reasons in favour of the adoption of electricity will be referred to hereafter. It soon became apparent that for this particular service motor cars offered advantages not to be secured by the use of separate locomotives, whether steam or electric. Where trains are heavy and long, and where the weight on the driving-wheels is not a consideration, separate locomotives may be preferable; because it is undesirable to multiply machines, and it is an advantage to have all the machinery under the eye of the driver and readily accessible—in tunnel railways also there is more space for the motors in separate locomotives. In cases, however, where it is important to limit the weight on the driving-wheels, motor-cars afford an opportunity of running trains of any length without undue weight being thrown upon the structure. For instance, on the elevated railways of New York, the structures will not admit of heavy locomotives; and though the traffic is such as to tax the carrying capacity of the trains, run at the shortest possible intervals, to its utmost limit, and beyond considerations of convenience, larger trains cannot be introduced unless the structures can be strengthened or motor-cars be adopted.

Lighter trains, resulting in better speed with a given expenditure of power, also follow from the use of motor-cars. As an illustration of this derived from actual experience, the trains of the Overhead Railway may be compared with those of the City and South London Railway. In the former case the electrical equipment for motive power adds 6 tons 7cwt. to the weight of carriages seating 114 passengers; while in the latter the corresponding weight (the locomotive) is 10 tons 7cwt., 96 passengers being carried. The avoidance of shunting at the terminal stations is another important advantage attending motor-cars. Every separate movement of even a light locomotive absorbs a comparatively large current, thus accentuating the irregularities of demand, already sufficiently variable, upon the generating engines and dynamos. Time is saved at the terminal stations, and siding accommodation is reduced in length. Wear and tear of all kinds are reduced, and the first cost of the trains is considerably less.

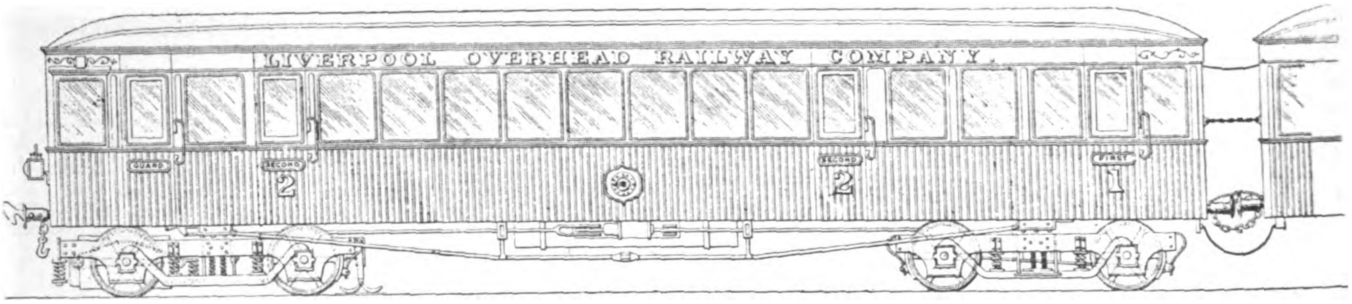

FIG. 7.

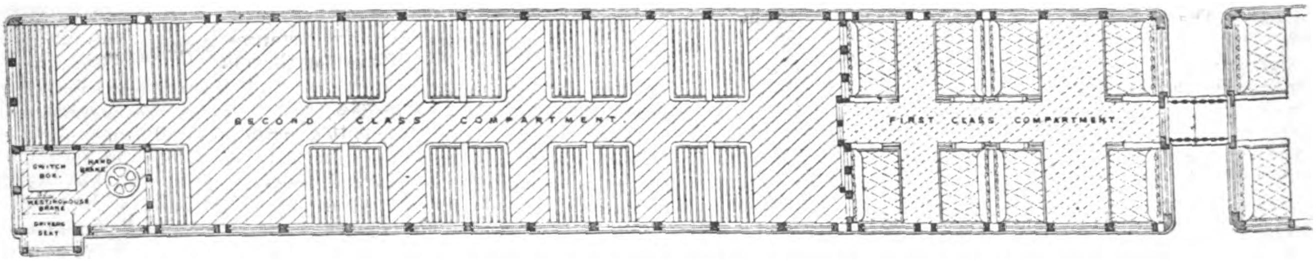

FIG. 8.

The design of the carriages (Figs. 7 and 8) received much consideration, and the result is satisfactory, both as regards weight and convenience. A train consists at present of two carriages, each 45ft. long and 8ft. 6in. wide, on two bogies, 32ft. apart from centre-pin to centre-pin, with 2ft. 9in. wheels, 7ft. wheel-base, and pressed steel frames. The carriages are all exactly alike, and contain accommodation for 16 first-class and 41 second-class passengers in each carriage, with three side doors and a passage from end to end. The first-class passengers are at one end of the carriage, and the driver's box with switches, &c., is at the other. When the two carriages are coupled together to form a train, the driver's boxes are at the extreme ends, and the two first-class compartments are consequently together in the middle of the train. A small door through the contiguous ends of the carriages enables the guard or attendant to pass from end to end of the train.

The motors, one at each end of the train, are controlled from either end; the driver, of course, always travelling at the front end of the train and changing ends upon arrival at a terminus, carrying with him a key without which the motors cannot be operated. In a train thus arranged one driver and one conductor constitute the train staff, the guard as well as the driver having it in his power to cut off the current from the motors and to apply the brakes.

The trains are fitted with the Westinghouse automatic brake, deriving its supply of compressed air from a reservoir on the train, the reservoir having a capacity sufficient for two complete journeys

* The first of two Papers read before the Institution of Civil Engineers, February 27, 1894; the second being "The Electrical Equipment of the Liverpool Overhead Railway," by Mr. Thomas Parker.

Digitized by Google

and being recharged each journey from a receiver placed at the terminus at the north end of the line. This system of working the brakes was previously applied by Mr. Greathead and found to work well on the City and South London Railway, and has answered equally well here. The air compressors are, in this case, worked by a small electric motor, with a gas engine in reserve; and, pending the completion of the northern extension, the compressed air is conveyed a distance of about three-quarters of a mile through one of the gas-tube rails of the parapet to the present northern terminus at Alexandra Dock station. A hand-brake is also provided at each end of the train. The carriages are lighted by 32-c.p. incandescence lamps connected with the working current, and the stations are lighted by similar lamps connected with a battery of accumulators placed under one of the platforms at each station. These batteries are in duplicate, and are charged in series by the main generating dynamos. The carriages were built by Messrs. Brown, Marshall, and Co. (Limited), of Birmingham, for the Electric Construction Corporation, to whom was let, after competitive tenders had been received from leading electrical firms, the contract for the electrical equipment and rolling stock.

The site of the generating station was a question which gave rise to much discussion. It was important, with a view to economical working, that coal should be obtainable by railway direct without the expense of handling and carting; that a good supply of water should be available for condensing purposes; and that the station should be near the middle of the line. These conditions were fairly satisfied in the site eventually selected under the arches of the coal-railway of the Lancashire and Yorkshire Railway Company at Wellington Dock. The coal is here tipped direct from the railway trucks into large hoppers placed over the boilers, and is distributed by a conveyor to the shoots of the Vicars mechanical stokers with which the furnaces are fitted. There is thus no handling of the coal. Water from the adjacent dock is used for condensing, and the town water for the boilers. Mr. Thomas Parker, to whose skill is due the excellent design and construction of the electrical plant, supplements this Paper with an account thereof, and it is therefore unnecessary to describe here the details of that work.

The boilers are of the double-flue Lancashire type with cross tubes; they are of steel, six in number, each 8ft. in diameter by 30ft. long, with a working pressure of 120lb. per square inch, and Green economisers in duplicate are fixed in the main flues. The steam-and feed-pipe ranges are also in duplicate. The engines are four in number, each consisting of a pair of horizontal compound condensing engines, built by Messrs. Musgrave and Co., of Bolton, who contracted with the Electric Construction Corporation to supply the engines and boilers complete, and with the Company to erect the chimney shaft (165ft. high), foundations of boilers, engines, &c. The high-pressure cylinders are 15½in., and the low-pressure 31in. in diameter, with a stroke of 36in., fitted with Corliss valves driven by Trip gear, acted on directly by the governor. Each engine will develop 400 I.H.P. at 100 revolutions per minute with 120lb. boiler pressure. All the engines exhaust to one condenser of the tubular service type. The centrifugal circulating pump and air pumps are driven by a Musgrave "No-dead-centre" vertical compound engine, and the condensing plant is in duplicate.

Each engine drives an Elwell-Parker dynamo, from which the current is conveyed north and south along each line of the railway by the steel conductor already described. Hinged collectors of cast-iron, sliding upon this conductor, the top surface of which is about ¾in. higher than rail level, allow the current, when required, to pass through the motors and to return by the wheels and the rails to the dynamos. At the crossings the conductor is bent to form wings parallel to the rail to be crossed, in the same way as is usually done at rail crossings.

The question of the relative economy of the working of steam and electric locomotives is of great interest at the present time. The nearest approach to the Electric Overhead Railway at Liverpool seems to be the Elevated Railways in New York, worked by steam locomotives. In each case the trains are comparatively light, though the New York trains are heavier than those at present running on the Liverpool line, and in each case the stations are on an average about one-third of a mile apart. In 1889 an experiment was made upon one of the New York lines to determine the possibility and cost of working by electricity. The results of this experiment, with a continuous-current system of electric traction, were used with considerable effect in the Parliamentary Committee Rooms on behalf of the Metropolitan Railway Company against the proposed Central London Railway in 1890; and a description of the experiments and the results and conclusions derived from them, with details of the cost of working the steam locomotives on the Manhattan Railway, was published in a Paper by Mr. Lincoln Moss in October, 1890.* The main conclusion arrived at was that "the cost of direct electric propulsion would be four times that of steam locomotion" on the Ninth Avenue Railway.

It is not necessary now to describe in detail the arrangements and results of those experiments, but it may be interesting to mention that the New York experiments were made with a train of 53½ tons drawn by an electric locomotive of 9 tons or more (the exact weight is not given) over a length of 1¾ miles of line, with four intermediate and two terminal stations, and having gradients of $\frac{1}{100}$, $\frac{1}{70}$, and $\frac{1}{54}$ against, and $\frac{1}{100}$ with the load. The average speed attained was 9·4 miles per hour, stopping at the four intermediate stations; the average power of the generating engine was 176·8 I.H.P., and the average power applied on the railway was only 26·7 effective horse-power, giving thus an efficiency of 15 per cent. as regards the indicated and effective power. Estimates were made in detail of the cost of installing and working an electrical equipment capable of dealing with the traffic on the Ninth Avenue Railway, which is about 5 miles along. The total arrived at was £771,000, including 17 generating engines each of 600 H.P., dynamos aggregating 11,000 H.P., and electric locomotives alone costing £126,000. The estimated working expenses for motive power, excluding interest on the first cost, came to £135,000 per annum, or to over 3s. per train mile.

The actual cost of the whole electrical equipment of the Liverpool Overhead Railway, for six miles of line, has been little more that 5 per cent. of the above estimate for the Ninth Avenue line of five miles, and the working expenses for motive-power are about 4d. per train mile, the mileage being much below the capacity of the generating plant. With a train-mileage equal to that of the Ninth Avenue line the cost would not exceed 3d. per train-mile. The actual average consumption of coal on the Liverpool Overhead Railway is about 16lb. per train-mile for trains of about 38 tons weight with seating capacity for 114 passengers, running at an average speed, including stops at stations, of about 12 miles per hour; whereas the averages on the New York Elevated Railways are, as far as can be ascertained, 54lb. of coal per train-mile for trains of about 92 tons weight (including locomotives weighing 23 tons) running at an average speed, according to the official time-tables, of about 12 miles per hour, including stops at stations. On the Liverpool Railway, during the last half-year, over 95 per cent. of the trains were punctual to time. No returns are available as to the punctuality of the New York trains. The coal used at Liverpool is bituminous small coal (slack), whilst in New York it is anthracite of good quality. The New York fuel consumption includes the heating of the trains in cold weather; but, on the other hand, that of the Liverpool line includes the lighting of trains and stations and the working of the automatic signals. The working of the brakes is included in both cases.

It will thus be seen that, far from electric traction costing four times as much as steam-locomotive traction, it is actually less expensive after full allowance is made for the difference in the weights of trains and other circumstances, in the two cases considered; and when the mileage of the electric line increases the difference will be still more marked in its favour.

The Liverpool empty train weighs 31 tons 2½cwt., of which the electrical equipment for locomotion weighs 6 tons 6cwt. With all seats occupied by passengers the total weight is about 38 tons 6cwt.; but, on occasions, the standing room in the train is also fully occupied, bringing the weight to perhaps 50 tons. The weight of locomotive equipment is thus about 125lb. per passenger, and about 20 per cent. of the total weight of the train with all seats occupied, each passenger being taken at 140lb. weight. A comparison of these figures with those of trains on other railways using electric and steam locomotives is given in Table A :—

TABLE A.

Average weight of empty carriages (ex-motors) per passenger seat, in pounds	487	490	615	590
Weight of full train per passenger, in pounds	752	671	972	1,020

It need only be observed in reference to the above Table that the comparison is very favourable, so far as weights are concerned, to

* *Transactions* of the American Society of Civil Engineers, Vol. XXIII., p. 193.

Digitized by Google

the adoption of electric motor-carriages where practicable and otherwise suitable.

In other respects, also, not indicated in the above Table, the advantages of the Liverpool arrangement are considerable. The weight on the driving wheels of a full train is 13 tons 15cwt., or about 36 per cent. of the whole weight of the train. Taking the minimum available adhesion at one-seventh of the weight on the driving wheels, this gives about 115lb. per ton of train, and the motors give an equal tractive force with a current of 133 amperes. The electric locomotives of the City and South London Railway, weighing 10 tons 7cwt. each, give on the driving wheels 28 per cent. of the whole weight of the train similarly loaded, and an adhesion (at one-seventh of the weight) of 90lb. per ton; while the motors give a tractive force of 100lb. per ton with a current of 150 amperes. For comparison with steam locomotives, the District Railway trains may be taken. A train of nine carriages, weighing (empty) 87 tons, and seating 400 passengers, is drawn by a locomotive of 46½ tons weight (of which 35 tons 13cwt. is upon the driving wheels), having cylinders of 17in. diameter and 24in. stroke, and driving wheels, when new, of 5ft. 9½in. diameter. The weight on the driving wheels is therefore 19 per cent. of the full weight of the train, and taking again one-seventh of this, the available adhesion is 61lb. per ton of train. With 120lb. mean effective pressure in the cylinders, the tractive force, allowing for the friction of the engine, would be about 70lb. per ton of train. It should be observed that the tractive force given above for the electric motors is available only so long as the stated currents pass through the motors, and that, as the speed increases, the current and, to a corresponding extent, the tractive force, are reduced,

These comparative figures are shown in the following Table :—

Table B.

——	Liverpool Overhead Railway.	City and S. London Railway.	District Railway.

Locomotive with 120lb. mean effective pressure in cylinders	...	...	71
Maximum tractive force per ton of motors or locomotive, lbs.	750	184	234

* The tractive force is arrived at, in the case of the Liverpool motors, from Mr. T. Parker's statement, Minutes of Proceedings Inst. C.E., Vol. CXII., p. 238; and in the case of the City and South London motors, from Dr. Edward Hopkinson's statement, Minutes of Proceedings Inst. C.E., Vol. CXII., p. 221.

The last line of Table B brings out a strong feature of the electric motor or locomotive, viz., that weight for weight, it is much more powerful than the ordinary steam locomotive. The latter has not only to apply, but it has also to carry the materials for and to generate the motive power. In a separate electric locomotive this advantage cannot be utilised to the same extent as is the case in the motor cars, but it is still considerable; because, in the one case, the whole of the weight of the locomotive is available for adhesion, and the motors can always be relied upon to exert a tractive effort exceeding the adhesion due to their own weight and that of the frame and wheels carrying them; while, on the other hand, even in the case of tank-engines, only about two-thirds of their weight is usually available for adhesion. Having regard to the large tractive force available, relatively to the weight of the train, on the Overhead Railway, as shown in the Table, it is not surprising that the promptness with which the trains get up speed is frequently remarked upon by passengers.

Signals.—A line such as the Overhead Railway, worked by electricity, seemed to afford a favourable opportunity for the introduction of electric automatic block signalling; and, in inviting tenders for the electrical equipment, manufacturers were asked to include a suitable arrangement of automatic signals. The Board of Trade was subsequently approached with a view to obtaining the necessary sanction to so novel a departure in connection with the working of an important passenger line. The system proposed was that patented by Mr. I. A. Timmis, M.Inst.C.E., and, after careful investigation, the inspecting officers of the Board of Trade (Railway Department) recommended that provisional sanction should be given; and in December, 1891, subject to certain conditions recommended by the inspecting officers, sanction was received, and the system is now in use on the railway.

The signals are of the ordinary semaphore and lamp type, but they are operated entirely by electricity, applied by the motion of the trains without the intervention of signalmen. At each station, and for each line, are a "home" and a "starting" signal, no "distant" signal being necessary—or rather the starting signal being the "distant" for the station or "home" in advance. As a train passes each signal it sets it to danger, by operating a lever which breaks an electric current passing through a contact box placed at the side of the line.

A train having arrived at a station has behind it two signals both at danger, forming a block-section; viz., the starting signal at the last station and the home signal of the station at which the train is standing. Upon the train leaving the station, its starting signal or "starter" being at "line clear" is by the train put to "danger." In its further progress, at a point in this case two train-lengths beyond the signal, the train, by operating a lever of a contact box, closes a circuit. A break in this circuit at the "starter" has already been closed by that signal going to "danger," and the circuit being complete to the two signals in the rear block-section just mentioned, a current passes through it and causes an electro-magnet on each signal-post to lower the signal to "line clear," and to hold it in that position. It is obvious that should the circuit be broken at any point, the signal or signals in that circuit would go automatically to danger.

In order to reduce to a minimum the current required for this work, advantage is taken of the fact that a comparatively small current will suffice to hold an armature after it has been brought into contact with a magnet, by automatically switching in a resistance about the moment that contact occurs; the effect is to reduce the current from that necessary to give the pull to that requisite to hold the signal in the "line clear" position. The lowering current is supplied by the through circuit as described, but the holding current is supplied through a short local circuit, thus freeing the making contacts in advance for another operation. It is also obvious that each train has always at least one signal at danger behind it. The levers which effect the making and the breaking of the contacts in the boxes are actuated by a long bar attached to the rear bogie of each train on the near side. All the making and breaking contacts are in duplicate, and all the signal lamps have two incandescent lamps in each in parallel, so that if any one fails the other still gives light. The electric lamps are lit and the electro-magnets are operated by a current of 50 volts from a battery of accumulators placed at each station under one of the platforms. The batteries are in duplicate, and while one is discharging the other can be charged. They are charged in series from the main circuit of 500 volts, and also serve for the station lighting.

Besides a considerable saving in the first cost, as compared with ordinary signals, the automatic signals will lead to important economy in working; and for the purpose of establishing shorter blocks in order to deal with increasing traffic, even where ordinary signals are used at the stations, the system will, it is thought, be specially useful.

In addition to the automatic signals, electric bells are at present used between station and station. These are worked by the porter on each platform, and telephones are in use at all the stations, and are connected with the general manager's office.

The fares are uniform for any distance. On passing through a turnstile on to the platform a passenger pays either 2d. or 3d.; if the latter sum, he receives a ticket entitling him to travel in a first-class compartment, which ticket is collected on his leaving the train. The portion of the railway at present worked begins and ends upon the dock estate, but the short extension at the northern end now approaching completion, and the authorised southern extension will take the railway into or near residential districts, and will render it less dependent upon the dock traffic, which, though very considerable, practically ceases at six or seven o'clock in the evening. By extending the hours of working to accommodate this new traffic the expenses will not be materially increased, because it is at present necessary to employ two shifts of men.

The railway was inspected on behalf of the Board of Trade by Major-Gen. Hutchinson, R.E., C.B., Major Cardew, R.E., and Major York, R.E., and, having been duly passed, was fromally opened by the Marquis of Salisbury on February 4th, and opened for traffic on March 6, 1893. A ten-minutes' service of trains was worked for about two months, and since then a five-minutes' service has been maintained with perfect regularity and without mishap of any kind. On the last August Bank Holiday about 40,000 persons were carried in the space of eight hours.

The total quantity of iron and steel in the structure is about 22,000 tons. The total capital cost, including equipment and all other charges, has been about £550,000, or about £90,000 per mile of railway. The engineers are Sir Douglas Fox, Member of Council Inst.C.E., and Mr. J. H. Greathead, M.Inst.C.E., who were represented on the spot during the construction of the line by Mr. Francis Fox, M.Inst.C.E., and Mr. S. B. Cottrell, Assoc. M.Inst.C.E. To the last-mentioned gentleman great credit is due

Digitized by Google

for the able manner in which the arrangements for working the traffic have been made. In carrying out the construction of the railway many questions had to be determined by the officers of the Liverpool Corporation and of the Dock Board; and for the courtesy and assistance rendered, especially by Mr. H. P. Boulnois, Mr. George Fosbery Lyster, and Mr. A. G. Lyster, MM.Inst.C.E., in the settlement of these questions, the Authors desire to express acknowledgment.

The Paper is illustrated by a series of drawings and tracings, a selection of which has been made for the Proceedings.

The second Paper (Mr. T. Parker's) will appear in our next issue.

(To be continued.)

THE POTENTIAL AND CURRENT CURVES OF DIFFERENT TYPES OF ALTERNATORS, AND THEIR INFLUENCE ON THE CANDLE-POWER OF ALTERNATE-CURRENT ARCS.*

BY G. RÖSSLER AND W. WEDDING.

In working alternate-current stations it has repeatedly been observed in recent times that arc lamps which have been adjusted with every care in the factory had to be readjusted when in working, in order that they might burn quietly at the same pressure and current. The cause of this phenomenon, as was soon recognised, lies in the differences of the periodic potential-waves of the machines with which they were tested from those with which they were run. Should these curves appreciably differ, as may easily be the case if dynamos and lamps are not supplied by the same firm, it may even happen that a well-regulated lamp, when tested, cannot be made to burn quietly when run on a different machine. This fact renders it necessary in building alternators for arc lamp supply to attempt always to produce a definite particular form of E.M.F. wave.

In choosing this form of wave two conditions must be considered. Firstly, how does the lamp burn? and secondly, what illuminating power does it possess when run with different character of potential and current waves? An answer to these questions can only be obtained experimentally by simultaneous electrical and photometric observations on machines and lamps at present in use. The authors have made together such researches in the Electrotechnical Laboratory of the Technical High School in Berlin at Easter, 1894. The electrical portion is the work of G. Rössler and the photometric of W. Wedding.

PART I.—ELECTRICAL.

Three machines were available for the following experiments; a 5½ kilowatt machine, by Ganz and Co., four polar, with a rotating cross-formed armature (Fig. 1); an older small 480-watt machine, by Wechsler and Co., with four magnet poles on each side of the rotating armature (Fig. 2), both machines the property of the Electrotechnical Laboratory; and, besides these, a machine by Siemens and Halske, with 12 poles, specially built for their own use for the preparation of ozone (Fig. 3), and which was very kindly placed at the authors' disposal by the firm. The arc lamp used was an excellent one, coming from the works of Messrs. Körting and Mathiesen, of Leipzig.

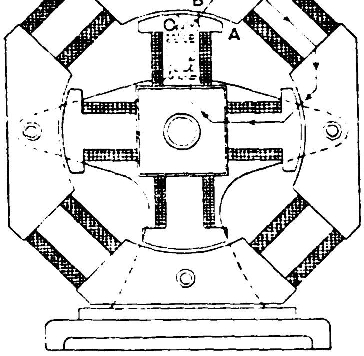

FIG. 1.

The determination of the curves of potential and current given by the machine was effected by the method described in principle by Joubert in his researches on a Siemens machine in 1881; one terminal of a voltmeter is joined to a terminal of an arc lamp, while the other terminals of voltmeter and arc lamp once in every revolution are connected together at a definite moment in the period. After suitable calibration of the voltmeter, one can measure the potential difference for every position of the armature, and the current is measured by the fall of potential across a suitable known inductionless resistance. In our case this momentary contact was produced as follows (Fig. 4): A contact block, A, imbedded in the surface of an insulating ring which rotates with the shaft, was permanently connected with the flat brass ring C, and the brush D, and touched once in every revolution the brush B, which, carried on an insulating brush-holder, E, could be moved over the

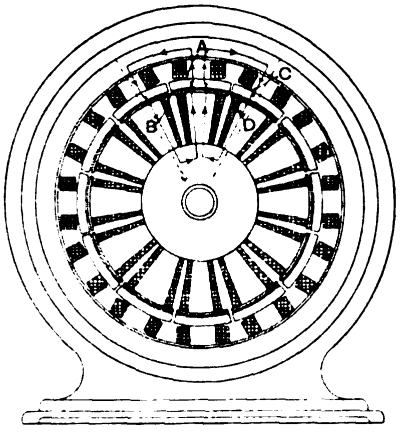

FIG. 2.

periphery of the divided arc F. B is permanently connected to one terminal of the voltmeter D to a terminal of the lamp or resistance; B could be connected with D at any particular point in the period by moving the sliding brush-holder E over the arc. For the practical work of observation the mechanical construction of the contact A B is of the greatest importance, and may easily become a source of many errors and much waste of time. The material known as stabilit, recently introduced by the Allgemeine Elektricitäts Gesellschaft, was used for the insulating ring, because

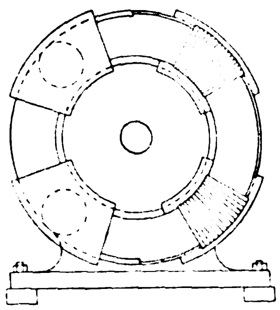

FIG. 2A.

of its excellent insulating properties, and its surface took quickly a beautiful polish under the action of the brush B. The measurements were made with an electrometer by Carpentier, which was very dead beat owing to its needle being suspended as a copper ring in a very strong magnetic field. In order to avoid variations in the reading of the electrometer, a Siemens mica condenser of one microfarad capacity was put in parallel with the electrometer. The discharges which take place owing to imperfect insulation when

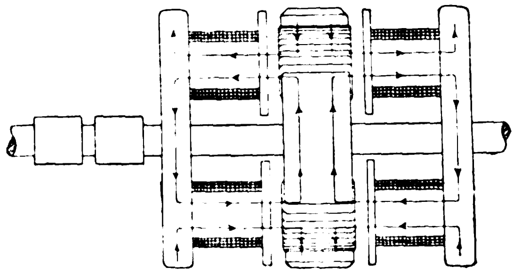

FIG. 2B.

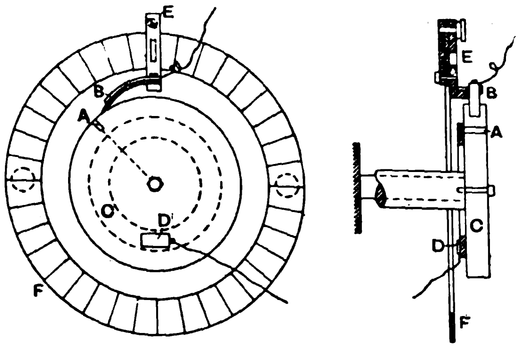
the contact A B is broken do not affect the potential difference of a condenser of this capacity to an appreciative extent; and, similarly, the condenser obliterates all irregularities in the driving of the machinery. The system of coupling the electrometer was as in Fig. 5. One pair of quadrants is connected to the needle and one terminal of the volts, the other pair being connected to the other terminal. The turning moment is then proportional to the square of the potential difference. And since in the Carpentier

* Paper read before the Verband der Elektrotechniker Deutschlands, 1894. Slightly condensed.

Digitized by Google

instrument the control is obtained by twisting the suspension, and this force is proportional to the angle of twist, it follows that the angle of deflection is proportional to the square of the potential difference.



F 4

The lower readings are, therefore, less sensitive than the upper, and the lower limit of this instrument was about 20 volts. For the determination of smaller potential differences, the needle was separately charged, as shown in Fig. 6, to about 100 volts. The deflection is then proportional to the potential difference between the quadrant pairs: 1 volt gave 20mm. deflection. Special switching arrangements enabled the coupling to be altered at any moment, and the electrometer and condenser to be discharged.

In calibrating the electrometer several important points must be noticed. The torsional rigidity of the suspension depends on the temperature, and, therefore, also the constant of the instrument. As the axis of rotation of the needle is unalterable by the construction of the instrument, a completely symmetrical position of the

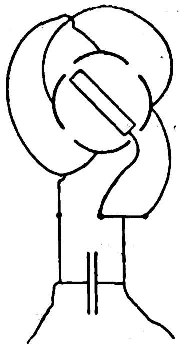


Fig. 5.

needle with respect to the quadrant is seldom attained. This has the disadvantage that the position of the needle alters when charged as in Fig. 6. To avoid the difficulties introduced by trying to treat the Carpentier instrument theoretically, the instrument was empirically calibrated over all its range, and this calibration

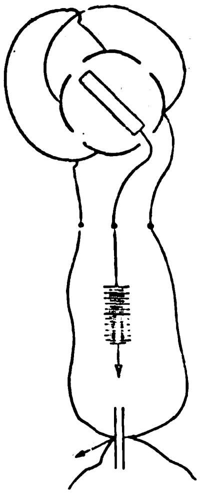

Fig. 6.

was repeated before each set of readings. An easy and convenient means of doing this was at hand in the form of a Feussner compensator with Clark standard cell, and a second small Pollak accumulator battery of 100 volts. As is well-known, one can easily produce in the main circuit of this compensator, by the aid of the Clark cell, small currents, as ·01 ampere, with the greatest accuracy. By an arrangement for switching known resistances into the circuit any voltage can be quickly produced.*

Since the charge only occupies a very small proportion of the whole time, it is necessary to calibrate by means of known voltage applied to the same rotating contact, so as to accurately reproduce the conditions. Much has been written by Hopkinson and others on the subject of the suitability of certain instruments for such measurements, but an empirical calibration of this sort immediately renders us independent of the peculiarities of the instruments used.

Besides the electrometer the following instruments were in circuit (Fig. 7):—

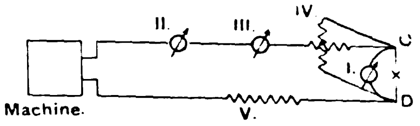

Fig. 7.

1. A Cardew voltmeter in parallel with the lamp C D.
2. A Thomson balance reading 0·1 – 10 amps.
3. A Schuckert alternate-current ammeter.
4. A Ganz wattmeter.

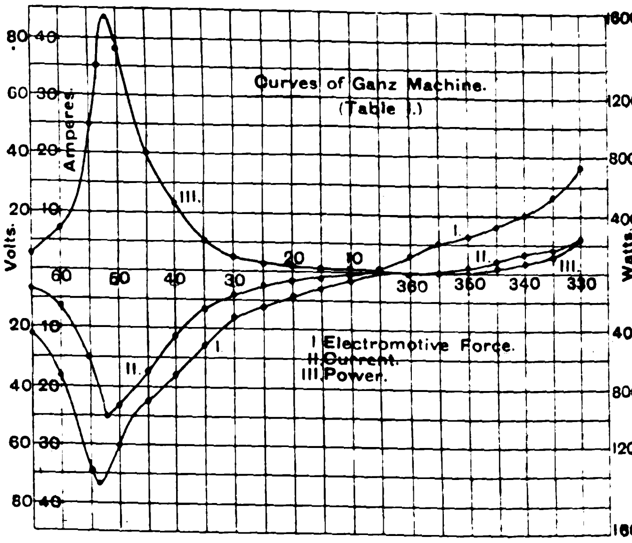

Fig. 8.

The inductionless resistance (5) was used in conjuction with the electrometer for the determination of the current curve. The instruments 1 and 3 measured the square root of the mean square of current and volts; the wattmeter (4) gave the power. The Thomson balance was only used in regulating the lamp, the Schuckert ammeter being used for keeping the current constant.

Measurements on the electrometer were only made when the signal was given that the lamp was burning normally. As the feed

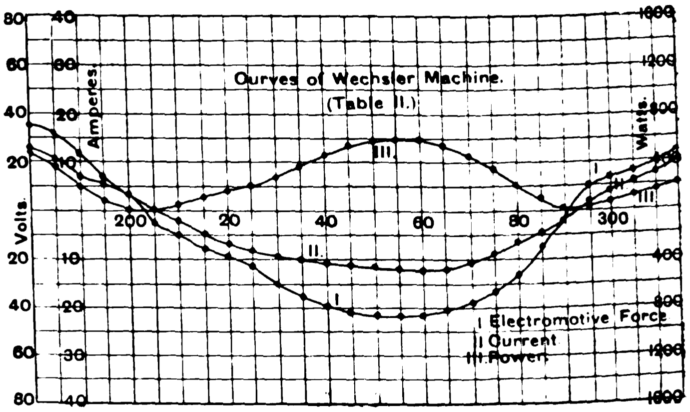

Fig. 9.

takes place in jerks, the electrometer reading is not steady, and therefore ten observations of current and volts were made for every position in the period. Altogether during the photometric measure-

* This apparatus was described in the *Zeitschrift für Instrumentenkunde*, April, 1890.

Digitized by Google

ments four pairs of curves were taken on the Ganz machine and two pairs on each of the others ; but, as these are all in perfect accordance, only one set need be given for each machine. In the following Tables the results of the last set of observations on each machine are given. The values therein given, and graphically represented in Figs. 8, 9, and 10 are obtained from the electrometer readings by subtraction of the total current and total power taken by the Cardew voltmeter and the wattmeter shunt.

Discussion of the Results.—The periodic variation of the electrical magnitudes is very considerably different in the three machines used. The Ganz machine has a quickly rising and quickly falling wave, the ordinates rising rapidly to an extraordinarily high point, falling rapidly, and remaining for the greater portion of the period at a very low value. So that the value of the energy supplied to the lamp (Curve III.) is very small from 35°—335°, and nearly the whole supply takes place over the range 35°—65°. The lamp, therefore, receives its energy in the form of an impulse lasting only about a third of the whole time. The reverse of this is the case of the Siemens machine (Fig. 3). Here the energy rises very slowly to a maximum value, on which it waits for some time, then declines slightly, rises again more sharply to a still higher value, and then falls quickly to zero. The current curve is even more regular, remaining constant in value for more than half the half period.

The Wechsler machine takes an intermediate position ; there is no very rapid alteration of the ordinate, and, on the other hand, no sustained maximum. This machine comes very near to having a sine wave.

The general character of these curves is easily explained on the theory of electro-magnetic induction from the magnetic design of the alternators. It is more difficult to follow in detail the reaction of the armature on the magnetic field and thence on the volt and current curves. As the types of alternator here used are of special interest as extreme types of what may occur in practice as regards electrical properties, some account must be given of the cause of these properties.

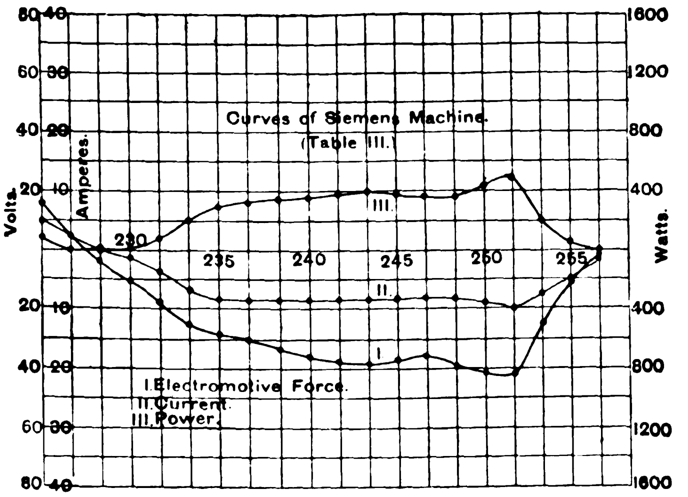

Fig. 10.

The investigation of the induction processes is best conducted on Faraday's lines of force theory (1) according to the known fundamental laws. If a closed conducting circuit be moved in a magnetic field an E.M.F. is produced, whose value in absolute units is the rate of change of the number of lines cutting the plane of the circuit ; (2) using the law of the magnetic circuit of these lines, according to which a certain magnetising force, determined by the ampere turns, always produces in a magnetic circuit a certain definite number of lines of force, inversely proportional to the magnetic resistance as calculated by certain definite rules. With these laws as starting point, the phenomena of the induction in these machines may be explained as follows :—

1. The Ganz machine (Fig. 1), armature and magnets made of charcoal iron, with armature and magnet poles of solid metal. Four magnetic circuits, taking the course shown for that position of the field magnets, the lines of force coming out of the right hand side of each limb, and passing in again on the left hand side of the next limb. A rotation of one-eighth of a revolution to the right may be divided into three parts. First, from the position drawn until the position is reached where the area taken up by the induction coming out is halved (when the point B is opposite A). The path of that going in becomes wider. The magnetic resistance of the circuit, and therefore the number of lines of force, is but little altered, and thus the induced E.M.F. is small. Second part : From this last point to that at which the left edge of the magnet pole is separated from the right edge of the armature projection by half the width of the pole face (point C, opposite A). On this part of the curve the lines of force coming out of the magnet into its pole-piece bend over into its left half, and the right half gets out of range. At the end the total area for the lines coming out and going in is equal to the area of the magnet limb. The magnetic resistance becomes somewhat greater, the number of lines of force diminishes slowly, the E.M.F. goes slowly up. Third part : From the end of the second part until the middle of the magnet pole is opposite the middle of the armature coil. In this short stretch the area of the induction path becomes rapidly smaller, the magnetic resistance rises, the number of lines of force diminishes, and the E.M.F. increases rapidly. During the second eighth of a revolution of the magnet the E.M.F. diminishes again in a symmetrical manner.

2. The Wechsler machine (Fig. 2a). Eight magnetic circuits, four on each side of the armature. Path of the magnetic lines as in Fig. 2b, as similar poles are opposite to one another. Smallest alteration of the number of lines is obviously when the armature coils are in the middle between two poles, and therefore zero of E.M.F. in this position. Greatest alteration when in the position shown in Fig. 2a, and therefore maximum E.M.F. here. In moving from one of these positions to the other there are no sharply marked divisions of the movement. The crossing of the induction from the magnets into the armature will always take place with great smoothness when the polar surfaces are divided from the armature iron by a large air gap, and this occurs in the Wechsler machine. The principle of large air gap is a useful one where sine curves of E.M.F. are to be aimed at ; the only important objection is the lowering of the electrical efficiency, but in America good dynamos are built with air space up to 15mm.

The Siemens machine (Fig. 3) gives a view of the magnetic circuits of the machine supplied by Siemens and Halske, as far as could be determined in the laboratory without taking the machine to pieces. The twelve magnet limbs, arranged as a star, come opposite as many armature coils wound on iron. Two of the magnetic circuits are indicated in Fig. 3. The pole-pieces of armature and magnet are so wide, that the edges of neighbouring pole-pieces are very close together, and herein lies the cause of its different pressure curve. If we again assume that in Fig. 3 the magnetic lines are coming out of the right hand side of the magnet limb and passing into the left hand side of the next, there exists when the armature is turned round no position where the number of lines of force suddenly alters. The rotation by a quarter period may be divided into two portions :—

First part : The magnet turns to the right between the pole-pieces of the armature, until B comes in front of A, and then D is also near C. During this part of the revolution the magnetic resistance increases, the lines from each magnet limb pass into two armature coils, and in the armature one portion of the induction is opposed to the other ; the result being during this portion of the revolution an increasing diminution of the lines of force—that is, a rising E.M.F.

Second Part : When B turns further out past A, D passes out over C, the path of the induction coming out of the limb B into the armature coil A becomes steadily narrower, and the lines coming from B pass half into A and half into C, when the induction cutting the armature coils is O. During this second half of the revolution the induction alters more rapidly than in the first part, resulting in a slowly rising E.M.F., which sinks again symmetrically as the rotation is continued.

The above considerations show afresh how extremely important the shaping of the pole-pieces for a given type of machine is in determining the character of the periodic curves of the electrical quantities. We have considered only the influence of the magnet fields, and the curves would be symmetrical were no other influence active. The deviations from symmetry are due to armature reactions weakening the field when approaching, and strengthening it when receding. To enter in detail into this effect is beyond the scope of the present Paper.

The accuracy of the above curves may be tested by comparing the average values obtained from them with the readings of the voltmeter, ammeter, and wattmeter. A wattmeter reads the average value of the watts, while the voltmeter and ammeter read the square root of the mean square, and this must be taken into account in measuring the curves by planimeter.

The comparison comes out as follows :—

Machine.	Volts.		Amperes.		Watts.	
	Measured.	Calculated.	Measured.	Calculated.	Measured.	Calculated.
Ganz	29·9	29·6	9·49	9·06	267	264
Wechsler	31·1	31·8	9·50	9·25	298	293
Siemens.........	30·4	30·8	8·87	8·81	—	—

In the first two cases the photometric and electric measurements were simultaneous ; in the last the electrical measurement directly

Digitized by Google

preceded the photometrical, and the wattmeter was not read. The result is a closer agreement with the observed values.

A closer agreement could not be expected when driving so unsteady a load as an arc lamp. It must be noted that the phase displacement is very small, only about 1/18th of a half period. For the recognition of the nature of the arc, the determination of the cause of this small displacement is of great importance; for to prove that it took place at the arc itself would be to prove an E.M.F. in the arc. The question whether this back E.M.F. were due to self-induction or to an electromotive force in the arc itself would still remain unanswered. The experiments do not throw much light on the subject, as the back E.M.F. of the coils of the lamp cannot be accurately calculated. The only thing they prove is that no great phase difference exists in an arc lamp.

Influence of the Character of the Waves on the Regulation of the Arc Lamp.—The discussion of this question is best preceded by a short description of the arrangement of the lamp. It is a differential lamp, and its construction is indicated in Fig. 11. The two coils are over one another, the current coil A above, the pressure coil B below. The two carbons of equal thickness hang on the ends of a chain, passing over the chain wheel D. As the carbons burn away the rotation of D brings them together, and as they burn equally they are raised and lowered by equal amounts, thus remaining about in the same position as regards the reflector *e*. To regulate the lamp the coils each work on a split iron tube, *a* and *b*, which are both fastened to a brass rod, *c*, hung on the end of a three-armed lever, E. These tubes are symmetrically placed

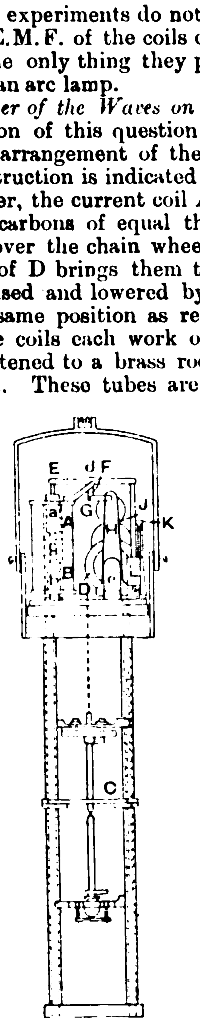

FIG. 11.

when E is horizontal, and their working is independent of any difference of phase in the currents which attract them. The working is as follows: When current passes through the lamp, the carbons being together, the current coil working alone pulls E down. The vertical arm F of the lever moves to the right, and by means of the connecting rod G moves H and D round the axle *e*, and draws the carbons apart. But H and D are only coupled together when arm J is pushed against K by the movement of H sideways. When the required pressure is attained the pressure coil lifts its core and feeds the carbons; the movements are made steady by a dash-pot L, whose piston can be weighted to control the regulation of the lamp.

These weights had to be altered considerably for the different machines, being heavier for the Ganz, and lighter for the Siemens machine; while with direct current the weight could not be sufficiently reduced to start the arc properly. This latter phenomenon is obviously due to the self-induction of the pressure coil, and resistance should be put in its circuit when used on direct currents. This also accounts for the differences between the machines, owing to the variations in shape of the E.M.F. curve. The author also gives reasons for working at a low-induction density in the iron cores if the lamp is to work on as many different kinds of machines as possible.

(To be concluded.)

Telephonic Communication in New Zealand.—It is proposed to establish a trunk line between Whananaki and Hikurangi, New Zealand. The inhabitants of Whananaki consider the telephone "a necessary adjunct to progress."

THE HUNTING OF GOVERNED ENGINES.*

BY JAMES SWINBURNE, M.INST.C.E.

Lord Rayleigh pointed out some years ago† that the ordinary explanation of the action of the electromagnet is an electrically-driven tuning-fork is incorrect, and that such a mechanism works in virtue of the self-induction of the electromagnet. As far as the action of the contact goes, it is the same whether the leg of the fork is receding from the magnet or approaching it; and if the force depended only on the contact, and was symmetrical, no power would be supplied to the system. It would be like a pendulum which is acted upon by gravity equally whether the bob is going up or coming down. To make the pendulum work continuously, gravity would have to act more when the bob was coming down. As this cannot be arranged, a clock has to do the work instead. In the case of Lord Rayleigh's tuning-fork, the magnet pulls harder when the leg is coming towards it than when receding, and thus gives power to the fork. In other words, the effect of the magnet lags, and thus becomes unsymmetrical. This is a most important principle, and it applies to a large number of varied cases of great importance, and of more interest to engineers than even electrically-driven tuning-forks. Broadly speaking, all kinds of continued vibration may be said to depend on this principle. Among these cases is that of the hunting of governed engines.

If a governor really behaved as it does in most text-books, and admitted steam in exact accordance with the speed of the engine, there would be no such hunting; but, unfortunately, a governor does not follow the variations of speed instantaneously. Apart altogether from questions of friction, or movement of heavy valve or expansion gears, many forms of governor, especially what may be described as the relay kind, alter the steam admission with some delay. The friction of the various parts and their tendency to remain in one position until the disturbing force comes up to a certain value, and to then move suddenly and overshoot the mark, increases this action. The result of this time lag in the action of governors is that in many cases engines, especially on light loads, get into a state of vibration known as hunting.

The orthodox way of treating such a subject would be to begin with the discussion of an engine with a fly-wheel and a frictionless governor with a dashpot or something of the sort, following a simple law. A system might thus be imagined which would fit a differential equation such as that used to find the current when an electrical condenser is discharged through an inductive circuit; and it might be possible to calculate the load which would just prevent permanent hunting, or any hunting at all. There are immense difficulties, however, for there are so many small causes of disturbance that such treatment would probably give no useful information. It may be best, therefore, to discuss the question verbally only, without expecting to arrive at very definite results.

When the load of an engine varies, for instance, by decreasing, if the steam supply remains the same, the extra energy goes to increasing the speed of the fly-wheel. Whether the speed of the engine follows the steam supply quickly or not thus depends on the fly-wheel. It also depends on the load. If a 1,000-H.P. engine is working at full load, and 900 H.P. is suddenly thrown off, and the governor does not act instantly, 900 H.P. is devoted to increasing the velocity of the fly-wheel, and unless the wheel has an enormous moment of inertia, or is turning very quickly, this power will increase its speed, say, 2 per cent. in a very short time. On the other hand, if the engine is only doing 100 H.P., and this load is suddenly reduced to 10, there is only 90 to increase the speed of the fly-wheel, and to increase it 2 per cent. will take ten times as long as in the former case. Putting the matter the other way, the engine obeys variations of steam supply more slowly at light loads, or, in other words, it obeys its governor more tardily at light loads. In practice many engines which run steadily at full load, hunt terribly when worked light.

Turn now to the governor. It is generally treated as complete in itself, without reference to the fly-wheel or engine load. A simple Watt governor, and most of the governors on small engines, have no appreciable time lag, except a certain sticking, due to friction, or to the absurd practice of putting a comparatively small governor to work direct on to a heavy expansion gear, or a stiff stuffing-box. These matters have been discussed in an able Paper by Ransom‡ recently. There is not very much tendency to hunting with such governors. Their drawback is that as the steam must be nearly shut off at no load, and full on at full load, the valve gear must be in different positions, and the governor must therefore be in different positions too. This means that the engine will be governed at a considerably higher speed at light loads. To cure this the obvious course is to make the governor isochronous. The drawback to this is that an ordinary isochronous governor is

* A Paper read before Section G of the British Association.

† Royal Institution, March 15, 1878.

‡ *Proceedings* of the Institution of Civil Engineers. Vol. CXIII., page 194.

Digitized by Google

not powerful enough if it has to move through a long range with a very small percentage of speed variation. It is likely to stick until the speed has varied a good deal, and then to move to its fullest extent. The result of this would be that the engine would be governed by having full steam and none at all alternately. I do not know why this method of governing should not be employed. If the governor works some light gear, such as the various modifications of the Corliss, this form of governor should work very well with a large fly-wheel. The cylinder would either get a charge of steam which would correspond to the full engine load, and which would, therefore, be expanded and worked in an economical way, or it would get none. This alternation of full load and no load is common in gas engines, and, for distinction, may be called the hit-and-miss method of governing. The only steam engine I know which employs it is the Parsons steam turbine. Of course, the great difficulty is the fly-wheel, especially in a slow-speed engine. If working at a tenth of its load it gets steam only every tenth revolution, and the fly-wheel must carry it round for nine. As high speeds are gradually coming in, it may be worth while to keep this method of government in mind, as it is most economical of steam, and as there is no time lag in the governor, there is no hunting.

Returning to the isochronous governor, the obvious method of overcoming the friction or weight of valve gear is to use some relay —to use a convenient electrical expression. The governor does not then act directly on the valve gear, but puts some screw or other mechanism into gear which works the expansion or throttle valve. Willans used a water relay. The governor worked a minute water valve, controlling a cylinder which worked the throttle valve. Such an arrangement can be made very accurate, as a very small movement of the governor, opposed by a very slight force, can be made to work the most obstinate valve gear. But we have at once danger from hunting, as there is considerable time lag in the governor. Suppose the load is suddenly decreased, the engine speeds up, and the governor begins to increase the expansion, but effects this slowly, and by the time the valves are right for the reduced load the engine is much above speed. The governor, therefore, goes on reducing the steam until the engine has far too little. It therefore slows down again. But the governor continues reducing the steam until the engine is slowed down to its normal speed. By that time the engine has far too little steam, so it goes on falling in speed. The governor then begins to turn on steam again, but it does it so slowly that the engine has fallen far below speed before normal steam supply is given, and the governor goes on turning up steam till the engine arrives at its normal speed, when it has far too much steam, and is again rapidly increasing in speed. This cycle of operations is repeated over and over again. It depends on the lag of the governor, the fly-wheel, and the load, whether the hunting is temporary, so that the variations of speed are less and less every time; or permanent, in which case the engine alternates between no steam and, perhaps, full supply. An engine which hunts permanently at very light loads often works perfectly over half-load.

An ordinary governor is thus apt to be insensitive and to allow the speed to vary with the load if designed not to hunt; and if arranged to work a relay, hunting results. An isochronous governor with a dashpot has, of course, a time lag too.

It is easy to make a governor which combines the advantages of both systems, and avoids the drawbacks.

A governor made by Messrs. Weyher, Richemond, and Co., of Pantin, may be cited as a good example. It is not isochronous, and it works directly on the steam control. I may mention that even in small engines the French arrange the valve gear so that it is very easily controlled. The variable detent is very common. In addition to working the steam control direct, any movement of the balls from the normal position puts a screw gear into motion, which slowly alters the intermediate gear, so that the engine finally runs at the normal speed whatever the load is. It is unnecessary to describe the particular gear employed; a typical case may be imagined. Suppose the expansion link is in connection with the middle of a lever, and the governor with one end A, the other end B being fixed; an increase of speed raises the end A of the lever and the middle, and you have an ordinary non-isochronous governor which gives a higher speed at light loads. Suppose, however, that any rise of the end A of the lever sets a train to work which slowly raises the other end, it will go on till the governor is in its normal position. We thus get a governor which does not hunt and gives the same speed at all loads. If the valve gear is heavy or stiff, the governor may work one end of the lever by means of a relay, but it must be a following relay, such as those employed in steam steering gear, so that the extent as well as the direction of the movement of the governor end of the lever is controlled by the position of the governor; and this gear should act as promptly as possible to avoid hunting. The other or relay gear then works slowly. In such a governor it will be seen that the end A of the lever eventually comes to its normal position in all cases, and only moves to counteract sudden variations of speed. The real control is effected by the slow-moving relay moving the other end B.

Instead of using one governor, a pair may be employed, one of which works direct on the valve gear, and the other by means of a slow-working relay. This method does not seem so simple as using a simple governor to do both.

These matters must have been worked out thoroughly by many engineers, and they appear so simple that one almost feels ashamed to bring them forward here; but in looking the matter up I find the governor is generally treated by itself, without reference to the engine. I have, therefore, thought it might be worth while to bring this subject forward, and trust you will bear with me for having put it in such a very elementary manner.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 17, 1894.

The American Association for the Advancement of Science inaugurated its forty-third annual meeting at Brooklyn yesterday (August 16th). In the morning Prof. Daniel G. Brinton delivered a presidential address, and in the evening Prof. Harkness, the retiring president, read a Paper on "The Magnitude of the Solar System." The vice-presidents of the various sections delivered addresses during the afternoon, none of which was on an electrical subject. The officers of the sections of physics are Prof. W. A. Rogers, president, and Prof. B. W. Snow, secretary, and the corresponding officers of the section of mechanical engineering and science are Profs. Mansfield, Merriam, and John Kinealy. The only electrical Paper thus far read was one this afternoon by Prof. Snow on the "Directed Velocity of the Particles in the Electric Arc." But few of the Papers have been printed, and it is not probable that electricity will play a part any more considerable in this meeting than it has in past ones. The American Institute of Electrical Engineers and the periodical scientific press in this country are the means of publicity chosen by American electrical scientists, who rarely read Papers at the Association meetings.

Revival of Business.—The passage of the Tariff Bill by Congress promises greatly to stimulate electrical business, which has been in a most unsatisfactory state during the past year. During that time there have been numerous failures, the latest being that of Queen and Co., Philadelphia, who for more than a generation have occupied the same position in America that Elliot Bros. have in Great Britain. One of the notable features of this period of depression has been the fraternal spirit shown in the trade toward its weaker members, the contrast in this respect with other branches of business having been frequently remarked. As an indication of the upward tendency we may cite General Electric Stock, which is now quoted 42, a rise of more than 6 points in a short time.

Municipal Electric Lighting.—The experience of the municipality of Detroit in electric lighting has not been encouraging toward the adoption of this system in America. More than a year has passed by since the decision to erect a plant was made, and, though much money has already been spent, little progress has resulted. Politicians have eagerly taken advantage of every step for the purpose of gain; and, if the plant is finally finished, it looks as if it will be merely used for corrupt ends. The letting of contracts was bitterly contested by different factions in the Council in the interest of different firms, and it is stated that the dynamos of the firm who finally received the contract may be rejected in the interest of unsuccessful bidders. A local paper comments on the situation as follows:—"After the lapse of one year the city finds itself with an elaborate white elephant on its hands. The people cannot fail to realise that the creation of the new department has simply increased the opportunity for more wrangling in the city government, and the facility with which private parties may control public affairs to suit themselves." As the change was brought about by charges of corruption of city officials and councilmen under the previous system of private ownership, the outcome is a sad commentary on American municipal government.

CORRESPONDENCE.

SINE CURVE ALTERNATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With regard to the lately so-much-discussed question of "sine wave" or "not sine wave," I may give, to supplement my former statement, the results of some tests recently made of the core loss of a 200-kilowatt transformer, which very plainly bears out my statement. With the generator giving very closely a sine wave, the observed core loss was 3,300 watts; while with the wave of an iron-clad alternator, at the same voltage and same frequency, the core loss was found to be only 2,860 watts, giving an advantage of over 13 per cent. in favour of the distorted wave of the ironclad. I may add that in this case the distortion of the wave was larger than usual, the ironclad being speeded down to the low frequency of 25 cycles.—Yours, &c., CHAS. P. STEINMETZ.

Schenectady, N. Y., August 17, 1894.

DOUBLE v. SINGLE TROLLEY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: So much has been written on this subject that it would seem that experience is the only thing likely to settle it.

There is another suggestion, which has not yet to my knowledge been tried, and which seems to be a sort of intermediate step.

With the adequate metallic returns now required by the Board of Trade, the difficulties of the earth return will probably be almost entirely confined to the more extensive systems—such as we may hope to see shortly in some of our larger towns—and it is to such that the following suggestion is most suitable.

By applying the three-wire system to tramway work in such a way that, say, the up line formed one side of the system and the down line the other, the earth return forming the third wire, the earth current on an extended system could probably be reduced to a comparatively small quantity, the excess, if desirable, being arranged always on the positive side.

A thoroughly good bonding of the rails would still be necessary, but underground feeders would be saved, and the advantages of the three-wire system be gained.

It might appear at first sight to produce some complication in the generating plant; but these difficulties might be overcome on similar lines to the way they are met in some of our lighting stations—viz., by the use of accumulators, which need not all be placed at the generating station, and by the use of motor transformers, which could with advantage be combined with the mechanical storage.—Yours, &c., A. G. SEAMAN.

August 28, 1894.

HIGH-SPEED FLY-WHEELS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to your editorial remarks on my letter on this subject in your issue for last week, I think that most practical engineers will agree with me that in such a question as this actual experience, even if American, is a safer guide than purely theoretical considerations.

I may, therefore, mention that in the pattern of Howell torpedo adopted by the United States Government the 14in. fly-wheel runs at a peripheral speed of 611ft. per second, while in a larger type of similar torpedo manufactured by the Hotchkiss Ordnance Company, the peripheral speed of the 18in. wheel employed is 706ft. per second. Before leaving the shops these wheels are run up to a speed about 20 per cent. in excess of the above. Such test is not for flying to pieces, but only for the elastic limit, and the wheel must show no deformation after it. As a matter of fact, the wheels would not fly to pieces until above double the above speeds had been reached.

It may also be pointed out that the steam wheel in the small Laval steam turbine, running at 30,000 revolutions per minute, has a peripheral speed of 575ft. per second, although, having regard to the apertures cut in it, this wheel cannot be nearly so strong as a solid one. Moreover, in the Parsons turbines used at Newcastle, Cambridge, and Scarborough, the 27in. diameter low-pressure wheel, at 5,000 revolutions per minute, has a peripheral speed of about 590ft. per second, though this also has holes in it and is a thin disc, which would not stand so great a strain as a solid cylinder. Further, these Parsons wheels have been run experimentally at considerably higher speeds than the above, and they do not begin to show any deformation until nearly twice their normal speeds are reached.

With regard to the practicability of strengthening high-speed fly-wheels such as I have suggested by means of hoops shrunk on the outside of them or by means of tightly wound steel wire, it seems to me very doubtful whether such methods of strengthening would offer appreciable advantages over a solid steel wheel. These methods of strengthening are, of course, those ordinarily employed in the manufacture of big guns; but it must be remembered that the conditions of strain in a big gun and in a fly-wheel are very dissimilar. While in the former the whole of the strain is set up in the interior, and, assuming the material to be incompressible, reaches each succeeding concentric layer with a force inversely proportional to the square of its distance from the axis, in a fly-wheel the case is quite different, and the centrifugal force tending to rupture the wheel acts upon every portion of it. Consequently, in a wheel the outer circumferential layers are already pretty fully loaded, owing to their own tangential inertia, and it does not seem advisable to put extra strain upon them for the purpose of assisting the interior. —Yours, &c., A. A. C. SWINTON.

S.W., August 29, 1894.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," being four Lectures delivered before the Royal Institution in April-May, 1894, by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is in preparation, and will shortly be published.

"THE WORK OF HERTZ."—The lecture delivered by Dr. O. J. Lodge at the Royal Institution on June 1st is reprinted with corrections and additions, and many illustrations, price 2s. 6d. net.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

TENDERS INVITED.—The Corporation of Edinburgh invite tenders for the supply of arc lamp-posts in connection with the electric lighting of the city. Copies of the specification can be obtained from Mr. E. W. Monkhouse, the Resident Electrical Engineer, Dewar-place, Edinburgh, from whom all information may be obtained; as also from the Consulting Electrical Engineer, Prof. A. B. W. Kennedy, 14, Old Queen-street, Westminster, London, S.W. Tenders must be sent to Mr. William Skinner, Town Clerk, City Chambers, Edinburgh, not later than 10 a.m. on the 17th prox. Some further particulars appear in our advertisement columns.

——— The Government of Canada invite tenders for the manufacture, laying, and maintenance of a submarine electric cable across the Pacific, from Canada to the Australasian Colonies. Conditions can be obtained at the Office of the High Commissioner for Canada, London, S.W., and proposals must be sent in to the Minister of Trade and Commerce, Ottawa, on or before November 1st next. Proposals may be sent in under Forms A, B, or C. Form A provides for the cable to be owned and controlled by Government, worked under Government authority, and kept in repair by the contractor for three years; under form B the cable is to be owned, maintained, and worked by a subsidised company; and under form C the cable is to be owned, maintained and worked by a company under a Government guarantee.

——— The Portsmouth Corporation invite tenders for the purchase of certain electrical plant at the Town Hall, Portsmouth, which is no longer necessary now that the building is connected with the central electric lighting station. Tenders much reach the Town Clerk by Saturday, September 22nd. Some further particulars appear in our advertisement columns.

——— The Postmaster-General invites tenders for the purchase of a quantity of old copper and other metals, insulated wire, and other old telegraph stores. Tenders must be sent to Mr. Charles E. Stuart, controller of stores, Telegraph-street, London, E.C., by noon, on Thursday, September 13th. Some further particulars appear in our advertisement columns.

Digitized by Google

TENDERS INVITED.—Our advertisement columns contain a notification that the proprietors of the Empire Palace of Varieties, Barnsley, require tenders for the lighting of the outside of the hall by electricity. These tenders must reach Mr. Edwin Haigh, the Manager, on or before Saturday, September 8th.

——— Tenders are invited for the erection of the electric light and power station at Shrewsbury, particulars of which can be obtained of Mr. A. E. Lloyd Oswell, Architect, Dana Chambers, Shrewsbury.

——— The Cheltenham Corporation invite tenders for the supply of junction boxes, covers, and other castings, which must reach the Town Clerk on or before September 8th.

TENDERS ACCEPTED.—The Electric Lighting Sub-Committee of the Edinburgh Town Council have accepted the tender of Messrs. S. Z. de Ferranti (Limited) for steam alternators, switchboards, and rectifiers, and that of the Silvertown Company for insulated cable, representing together between £4,000 and £5,000.

——— The tender of Messrs. Fletcher and Hirst, of Burnley, has been accepted by the Wolverhampton Corporation for putting the necessary wires and the selected fittings into the Corporation buildings to be lighted electrically, the amount of their tender being £609. The tender for the supply of the pendants has not yet been selected.

SALES BY AUCTION.—We would remind our readers that the sale by Messrs. Fuller, Horsey, Sons and Cassell, of the extensive manufacturing premises in the occupation of Messrs. Latimer Clark, Muirhead and Co., is to take place on Tuesday next at 11:30, and that the plant and machinery will be sold by them on Tuesday, Wednesday, Thursday, and Friday next at 11:30 precisely each day. Some particulars appear in our advertisement columns.

SALE OF PLANT.—Mr. F. D. Leslie, the Receiver and Manager of Messrs. Woodhouse and Rawson United (Limited) announces in our advertisement columns that the whole of the stock now at 88, Queen Victoria-street, E.C., and at Bradford, Glasgow, and Chiswick, consisting of dynamos, motors, electric and steam launches, and every requisite for electric lighting, will be on sale at considerably reduced prices until September 30th.

APPOINTMENT.—Mr. E. G. Jones, late assistant engineer to the St. James and Pall Mall Electric Light Company, has been appointed electrical engineer to the Corporation of Cape Town.

DISSOLUTIONS OF PARTNERSHIP.—Messrs. Sydney Cummins Smith and William Habgood, electrical engineers, Great Missenden, have dissolved partnership; all debts due to and owing by the late firm will be received and paid by Mr. W. Habgood.

——— In reference to the note in our last week's issue respecting the dissolution of the firm of Messrs. Donnison, Parmiter, and Barber, we are requested to state that the business is being carried on as usual at Manchester by Messrs. Parmiter and Barber.

BANKRUPTCIES.—Percy Hector Pitman, trading as P. Pitman and Co., hydraulic, electrical and general engineers, of 3, Park-road, Cheadle, Cheshire, has been adjudicated a bankrupt.

——— A first and final dividend of 3s. 4½d. in the £ in the estate of Selina P. A. Rowbottom, lately trading as S. S. Rowbottom and Co., electrical engineers, at 82, Abbey-street, Derby, is now payable at the Official Receiver's, Derby.

LIQUIDATIONS.—A petition has been presented for the winding up of Martiny (Limited), and is down for hearing at the Royal Courts of Justice, Strand, W.C., on October 24th.

——— The Ries Electric Specialty Company, of Baltimore, U.S.A., has made application for the appointment of a receiver to take charge and close up the business of the Company. Mr. Elias E. Ries, the President, states that this step is necessary, owing chiefly to internal dissensions amongst some of the stockholders; but he intends to shortly reorganise the Company under more favourable auspices.

POSTAL REGULATIONS FOR PRIVATE CARDS.—To-morrow (Saturday) the public will have the privilege of sending through the inland post, as postcards, private cards bearing halfpenny adhesive stamps. These cards must be composed of ordinary cardboard, not thicker than the material used for the official postcard. The form should be similar to that of the present postcard. The minimum size must not be less than 3¼in. by 2¼in., and the maximum size must correspond as nearly as may be to that of the inland postcard now in use. The regulation for the address side of the card is somewhat different to that now existing. Written or printed addresses may be placed on this side, and the words "immediate," "forward," "local," or similar instructions may be added, but no other written or printed matter will be allowed. On the reverse side any written or printed matter may be placed, but no adhesive matter other than a receipt stamp is permitted. The cards must not be folded, except, of course, in the case of reply postcards, to which the above regulations apply.

PERSONAL.—Messrs. G. E. Piggott and Co. desire us to state, in reference to a circular issued by Mr. Applegarth on the subject of a "Register" issued by them, that Mr. Piggott, on severing his connection with Mr. Applegarth, informed that gentleman of his intention of starting in business for himself and issuing a "Register," and that there is, therefore, no question of his having acted unfairly or improperly.

BRITISH EXHIBITS AT INTERNATIONAL EXHIBITIONS.—The British Exhibitors' Association have presented to the Secretary of State for the Home Department a petition containing an energetic protest against the failure on the part of the Department to appoint efficient executive officers at the late World's Fair at Chicago, to which reference is made elsewhere. The signatories point out that to exhibitors at foreign exhibitions, especially when held at a considerable distance from Great Britain, it is above all things necessary that efficient executive officers and assistants should be appointed to devote themselves exclusively to the interest and well-being of the British section, and to be in close touch and sympathy with individual exhibitors. This was most certainly not the case at Chicago. The petitioners also express strongly their opinion that the headquarters of the British section at these exhibitions should be regarded in future as the headquarters for the exhibitors also, who were at Chicago dependent on the generosity of the American authorities even for a room in which to hold their meetings. Owing to the very scanty decoration of the British Section, this was very much less attractive than other portions of the exhibition. This was especially noticeable, as every other nation exhibiting at the Fair were well catered for in this respect; and the petitioners (who represent nearly the whole of the British exhibitors at Chicago) conclude by calling the attention of the Home Secretary to the great importance of the above items to those firms who, at much expense and frequently at considerable inconvenience, participate in these exhibitions in order that British trade may be effectively represented.

CHLORIDE CELLS.—The Chloride Electrical Storage Syndicate (Limited), send us price lists and particulars of their traction (T_B) cells. The circular states that these cells can be employed for either high or low discharge rates, and are suitable for all classes of work where the cells are subjected to vibration.

MESSRS. E. DUCRETET ET L. LEJEUNE.—We have received from Messrs. Ducretet et Lejeune, of Paris, copies of pamphlets describing the electrical instruments manufactured by them. Among these we notice an ingenious system of long-distance thermometers, a recording pyrometer, and an electric meter.

ALLEGED THEFT.—On Monday, at the Glasgow Central Police Court, a man named Edward Morway, described as a Hungarian, was committed for trial for stealing a large quantity of platinum from premises occupied by Sir William Arrol and Co., by whom he was employed as an electrician, and for obtaining £64 from the firm's cashier by false pretences. It was alleged that he had sold the platinum to a Glasgow electrician.

BROMSGROVE.—The adjourned meeting of ratepayers to consider the question of lighting the town by electricity was held in the Town Hall on Thursday, last week, when a resolution in favour of permission being given to Messrs. Hemming and Co., of Birmingham, to erect the necessary plant was carried unanimously. Representatives of the Company were in attendance, and stated that, subject to receiving adequate promises of support, their proposals would be seriously pursued. It was proposed to use both steam and water power, the latter being utilised as much as possible.

BROUGHTY FERRY.—The Northern Electric Supply Company having informed the Police Commissioners of their intention to apply for a Provisional Order, the Borough Gas Committee have consulted an electrical engineer, and made inquiries, with the result that a special meeting was held on Monday to consider the advisability of the Committee applying itself for a Provisional Order. After some discussion the meeting was adjourned until Monday without a conclusion having been arrived at.

CHURCH LIGHTING.—St. Peter's, Eaton-square, S.W., is being installed for the electric light.

CLUB LIGHTING.—The Conservative Club, Glasgow, has entrusted the contract for the whole of the electric light fittings for the installation shortly to be completed, with Messrs. Rashleigh Phipps and Co., of London.

COLCHESTER.—Before coming to a decision as to the establishment of a central electric lighting station, the Lighting Committee of the Town Council have issued a circular to the inhabitants of the district proposed to be so lighted, with a view of ascertaining the probable demand for the current.

DENBIGH.—The Town Council have requested Mr. Vaughan Hughes to supply them with an estimate of the probable cost of lighting Denbigh by electricity, and the Town Clerk has been instructed to obtain what information he can as to municipal lighting generally.

Digitized by Google

DUNBLANE.—The Police Commission have decided to oppose any application made for obtaining an Electric Lighting Order, and will themselves apply to the Board of Trade for an Order.

DUNDEE.—The Gas Commission have authorised the extension of the electric light to the police offices.

ECCLES.—The Tramways and Lighting Committee of the Town Council have received a report from Dr. J. Hopkinson on the proposed electric lighting of the main thoroughfares of the borough.

EDINBURGH.—At the last meeting of the Town Council the Cleaning and Lighting Committee recommended that George-street, Charlotte-square, and St. Andrew's-square, and the streets leading from these to Princes-street, should be lighted by electricity; but after some discussion it was decided to wait to see the result of the electric lighting in the streets already agreed upon.

HERTFORD.—The Lighting Committee of the Corporation have drawn up their report recommending that the proposed electric lighting scheme be carried out as speedily as possible; that the engineer be instructed to prepare the detailed plans for carrying out the scheme, and the requisite forms of tender; and that application be made to the Local Government Board for their sanction to a loan of £6,000 for carrying out the scheme.

LEEDS.—The Lamp Committee of the Corporation have appointed a Sub-Committee to consider an offer recently made by the Yorkshire House-to-House Electricity Company to light certain of the streets of Leeds by electricity.

LEICESTER.—The Gas Committee reported at the last meeting of the Town Council that the electricity supply works were proceeding satisfactorily, and it was hoped that they would be able to supply the current by the end of October. The price has been fixed at 6d. per unit.——A special meeting of the Town Council was held on Tuesday evening, when the Finance Committee recommended the creation of £135,000 of Leicester Corporation Three per Cent. Redeemable Stock for the purpose of raising the money for the construction of water and electric lighting works. It was stated that the larger portion of this sum would be required for water purposes, £17,574 being the balance of the amount sanctioned by the Local Government Board to be expended for electric lighting purposes. The report was adopted.

LONDONDERRY.—At a special meeting of the Corporation, held on Friday last, a report was read from Mr. Christie, the resident electrical engineer, detailing a list of occasions on which the electric cables had fused. After a short discussion the meeting was adjourned for a week to enable Mr. Blake, the electrical engineer, under whom the works were constructed, to draw up and submit a report on the subject generally.

NEWCASTLE-ON-TYNE.—The Tramways Committee of the Corporation have received a communication from Messrs. Ledbitter and Harvey, suggesting that an electric tram line be run from the central station to a point opposite the church in Church-street, Walker, which they propose to work on the overhead system. Another tramway scheme discussed at the same meeting was for the putting down of a cable line, but Mr. Eustace Smith pointed out that owing to the section of the line being only about four miles in length, the expenses of a cable line would be prohibitive, as he had estimated the cost of working at 10d. per mile. The Committee, however, favoured the cable scheme, and requested Mr. Smith to consider the matter, and report to a future meeting of the Committee.

NOTTINGHAM.—The new electric light works in Wollaton-street are rapidly approaching completion. The boiler-house, engine-room, and battery department are practically finished, and as the whole of the plant has also been laid down, there is every probability of the installation being completed at an early date.

PONTYPOOL.—The electric light is to be turned on in the new market to-morrow (Saturday). The installation has been supplied by a Bristol firm.

WARMINSTER.—On Tuesday the Local Board had before them a recommendation of the Electric Lighting Committee that the electric light should be extended to the top of Town Hall Hill. Mr. Brown, of Walsall, the electrical engineer, had been consulted on the matter, and had arranged to shortly visit Warminster, and it was decided to adjourn the further consideration of the matter until he had advised as to the suggested extension.

WHITECHAPEL (LONDON).—The District Board of Works for Whitechapel have now under consideration various schemes for lighting the district by electricity. Prof. H. Robinson is advising the Board on the subject. It is intended to follow more or less the policy adopted by St. Pancras in the use of a combined dust destructor and electric lighting station and plant. Several schemes have been submitted by Prof. Robinson, and these are marked A, B, and C. By scheme A it is proposed to give every public lamp in the district a light of about 10 c.p. more than at present. The estimate for an installation for the compulsory area (Whitechapel-road, High-street, Commercial-street, Leman-street, and part of Commercial-road) only was £44,500, and the total annual cost £8,266. There would then be current available for private use of the value of £8,333, at 5d. per unit; and Prof. Robinson, who has surveyed the district, and compared it with his experience of St. Pancras, is of opinion that the demand will soon exceed the supply. The total capital expenditure for this A system would be £72,250, and the annual cost £13,691, with an estimated income from private lighting of £10,433, leaving £3,258 to be charged to public lighting, which now costs about £5,000. Scheme B provides 500 arc lamps, each of 250 c.p., contrasted with 26,000 c.p. by the A scheme. The total outlay under this latter scheme is estimated at £74,750, the annual charge £16,059, and the income at £10,108, leaving £5,951 for public lighting, or an excess of £951 over the present cost. Scheme C provides 300 arc lamps, each of 1,000 c.p. The capital expenditure is estimated at £84,250, the annual cost £16,969, and the income £8,333, raising the sum to be charged to public lighting to £8,636, or £3,636 beyond the present cost. These schemes each include in annual cost the payment of interest and repayment of load in 42 years, and full allowance is also included for depreciation of plant. The Electric Lighting Committee of the Board are in favour of a comprehensive scheme; but are not prepared to recommend either of the three above until their investigations, which are being diligently pursued, are completed. Mr. Thomas Catmur, on behalf of the Committee, submitted the report embodying these schemes to the meeting of the Board on Monday last, and said that it was clear that, if they had electric light, twice or twenty times the amount of light which they had in the district now would be provided; but, of course, they would have to pay an extra cost, and what that extra cost would be was the speculative item in any scheme adopted. The report was favourably received by the Board, although some anxiety was expressed about the dust destructor, lest its efficiency should be in any way impaired by having extra duties to perform. Mr. Catmur, however, assured the meeting that on this point the most careful investigation had been made by the Committee and their expert (Prof. Robinson), and the conclusion arrived at was that the efficiency of the destructor as a destructor would be increased rather than otherwise.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

COMPANIES' MEETINGS AND REPORTS.

Crompton and Company (Limited).

An extraordinary general meeting of this Company was held on Wednesday, at the offices, Mansion House-buildings, E.C., for the purpose of considering, and if approved, of confirming the following special resolution passed on August 13th :—

"*That the capital of the Company be reduced from £300,000 to £280,000 by cancelling paid-up capital which has been lost, or is unrepresented by available assets, to the extent of £20,000 by cancelling 4,000 Ordinary fully paid-up shares of the Company, numbered 2,785 to 6,784 inclusive, which have been issued.*"

The SECRETARY (Mr. Francis R. Reeves) having read the notice calling the meeting.

The CHAIRMAN (Mr. R. E. Crompton), after reminding the shareholders that the objects of the resolution were fully explained by the Chairman (Viscount Emlyn) at the meeting at which it was passed, formally moved its adoption, which was seconded by Mr. H. C. HAWKINS, and carried unanimously.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "The Electrician" Electrical Trades' Directory and Handbook, 1894, pages 274-300, *&c., &c.*]

BIRMINGHAM STAMPING AND TOOL COMPANY (LIMITED).—This Company was registered on August 22nd, with a capital of £6,000, in £1 shares, to carry on the business of iron, steel and other metal stampers, piercers, spinners, drawers, tool makers, engineers, machinists, &c.

JOSEPH COOPER AND SON (LIMITED).—This Company was registered on August 27th with a capital of £7,500 in £5 shares, to acquire two businesses of tool makers and ironfounders carried on at Birmingham, and to carry on the business of ironfounders, mechanical engineers, tool makers, metal workers, &c.

EXPLOITATION (LIMITED).—This Company was registered on August 24th, with a capital of £1,250, in £5 shares, to acquire, develop, and turn to account patents, inventions, licences, concessions, &c., and to carry on the business of mechanical, civil, marine, electrical, hydraulic and general engineers, patent agents, &c.

FORUM CRUCIBLE SYNDICATE (LIMITED).—Registered August 22nd, with a capital of £1,500, in £5 shares, to carry on business as crucible manufacturers and dealers.

LYNTON AND LYNMOUTH ELECTRIC LIGHT COMPANY (LIMITED).—This Company was registered on August 27th with a capital of £8,000, in 1,000 £5 per Cent. Cumulative Preference and 7,000 Ordinary shares of £1 each, to acquire and take over as a going concern the electric lighting business now carried on at Lynton and Lynmouth by the Lynton and Lynmouth Electric Light Company, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, and manufacturers of and dealers in electrical apparatus and materials. The subscribers (with one share each) are :—Harry E. Brougham, Charles J. Fox, Charles Geen, J. Hamilton Benn, H. S. Miller, W. T. Longstaff, and Hans H. Benn.

SAYCEE ELECTRICAL SYNDICATE (LIMITED).—This Company was registered on August 22nd, with a capital of £10,000, in £1 shares, to acquire the patent rights No. 14,056 of 1893, in respect of an invention for "Improvements relating to Primary Batteries," also the patent rights No. 21,420 of 1893, in respect of an invention for "Improvements in Primary Batteries," and the patent rights No. 3,674 of 1894, for "Improvements in Primary Batteries and the depolariser used therein," together with the full benefit of the said inventions in Great Britain and Ireland, Hungary, France, Italy, Belgium, Austria, Spain, and Germany. The subscribers (with one share each) are :—Henry Hall, Charles W. Bloomfield, Frederick Chipperfield, Richard Paris, Henry M. Bentley, William H. Rumball, and George M. Gordon.

SPENCER AND CO. (LIMITED).—This Company was registered on August 23rd, with a capital of £12,000, in £10 shares, to carry on the business of mechanical and electrical engineers, iron and brass founders, &c.

ELECTRICAL COMPANY (LIMITED).—The annual return of this Company, made up to August 14th, has been filed. The whole nominal capital of £15,000, in £5 shares, has been taken up, and all issued with £3 per share considered as paid. Upon each of these shares a call of £1 per share has been made.

ELECTRICAL POWER STORAGE COMPANY (LIMITED).—The annual return of this Company, made up to August 2nd, has been filed. The nominal capital of £100,500 is divided into 100 Founders' and 20,000 Ordinary shares of £5 each. 66 Founders' and 18,257 Ordinary shares have been taken up, and 15,120 of the latter class have been issued as fully paid. The full amount has been called on the Founders' shares, and a call of £3 per share has been made on the remaining 3,137 Ordinary shares. The calls paid amount to £9,386. 15s. 7d., leaving £354. 4s. 5d. as yet unpaid. £400 has been paid on 4 Founders' and 400 Ordinary shares which have been forfeited.

ELECTRIC SEMAPHORE SIGNAL SYNDICATE (LIMITED).—A letter from the Secretary states that this Company never proceeded to allotment, and that the only members are the signatories to the Memorandum of Association. Under these circumstances, therefore, it is not proposed to file a return.

ELECTRIC TRACTION COMPANY (LIMITED).—The statutory return of this Company, made up to August 3rd, has been filed. Only 7 shares of £10 each have been taken up out of a nominal capital of £300,000, divided into 29,880 Ordinary shares of £10 each, and 1,200 Deferred shares of £1 each. No calls have as yet been made upon these shares, and the original subscribers are the only shareholders.

EXCHANGE TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to August 15th, has been filed. The nominal capital is £246,250, divided into 8,125 "A" and 16,500 "B" shares of £10 each. Of these all the "A" and 16,200 "B" shares have been taken up, and all the latter have been issued as fully paid; while 2,125 "A" shares have been issued with £8 per share considered as paid. Calls amounting to £9 per share have been made on 6,000 "A" shares, and £1 per share has been called on the 2,125 "A" shares, resulting in the payment of £56,023, leaving £102 in arrears.

CITY NOTES.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended August 26th were £878, as against £719 in the corresponding period of 1893, being an increase of £159. The total receipts for the half-year amount to £6,942, as against £6,647 for the corresponding period of 1893, an increase of £295.

ELECTRIC CONSTRUCTION COMPANY (LIMITED).—Notice is given that the transfer books of this Company will be closed from Aug. 30 to Sept. 13, inclusive.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to appoint a special settling day in, and to grant a quotation to the scrip and fully-paid scrip of £1,100,000 Three and a-Half per Cent. Debenture Stock of the National Telephone Company (Limited).

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended August 24th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,545.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 851.—Vol. XXXIII. FRIDAY, SEPTEMBER 7, 1894. PRICE FOURPENCE *Annual Subscription (U.K.), 18s.*

NOTES.

The wide and unique experience of Dr. Fleming in the manufacture and characteristics of glow lamps enables him to write on many points connected with the use of lamps with greater authority than, perhaps, anyone else in this country. The extract from his Royal Institution lectures, which we print this week, deals with the important question of efficiencies. Dr. Fleming carefully distinguishes between luminous efficiency, or the proportion of "eye-effecting radiation" to the total radiation, watts per candle-power of a new lamp, total watts per total candle-power over the whole life, and over the useful life. The reciprocal of watts per candle, the most popular idea of efficiency of a lamp, was at one time called the "strain" by Dr. Fleming, and is measured in decimals of a candle-power per watt, or candle-power per kilowatt or horse-power. The use of this reciprocal has been advocated by Mr. Swinburne and others; but the watts per candle seems likely to remain in common use. There is no end to the elaborate tests and experiments which may be made with lamps; but Dr. Fleming, in this portion of his lectures, discusses those only which bear on the value of the lamp to the user. The average consumer cannot be expected to study the relations between volts, candle-power, and life, to say nothing of resistance, and watts per candle, and load-factors; but there are a few practical considerations which electrical engineers can bring to his notice, both in the selection and in the use of lamps. Dr. Fleming qualifies the paradoxical "smashing point" in a very practical way, and he unhesitatingly asserts that no hard and fast comparison between the cost of electric lighting and of gas lighting is possible.

The mode adopted by Mr. T. Parker for calculating the power required for the service of the Liverpool Overhead Railway is of some interest, and the results which are described in his Paper, which we print this week, show that the expectations thus formed, were fully justified. We do not propose to revive the rope-driving *v.* direct-driving controversy here, and would only observe that it was a great pity that dynamos of such high commercial efficiency should be driven by ropes. The Eickemeyer system of armature winding, which has been used in building the motors, is undoubtedly a good one; but Mr. Parker rather implies that much of the success of the work is due to it. The chief points of this winding seems to be the good mechanical method of forming the coils instead of winding them, the neat way of putting them together, and the ease with which this operation can be reversed, thus detaching any injured coil. As far as standing the stresses of actual running is concerned, there are other windings which we think would be as good; and, fortunately, the work in this case has been so satisfactory that freedom from breakdown has not called the detachable feature into use.

Among a few of the illustrations in Mr. Parker's Paper, which we have not reproduced, are the indicator diagrams of the steam engines. We alluded some time ago, in connection with a lecture by Prof. Kennedy, to the way in which indicator diagrams are used and misused, and observed that while they are of the utmost importance to the engineer who makes the test, they are, as a rule, of very little use as illustrations to the report on the test. There can be no doubt that in this case some serious error or errors have crept in, and it seems nobody's business to discover them. Mr. Parker did not make the tests, but has simply published them. Mr. Greathead assumes no responsibility for them. He does not agree with us that the results are too good to be true. Some light is thrown on them in the discussion on the two Papers, which we intend to reprint. Fortunately—very fortunately—these efficiency tests do not in any way affect the cost of working, which is, after all, the most important feature of the work. The Railway Company soon found after carefully watching the outlay, and noticing that the trains were running with perfect regularity and without breakdown, that the contractors were making money out of the contract for running the line at 4d. per train mile; and accordingly they terminated the arrangement, and at once effected a considerable saving. Many a contract of this kind for electric traction has been made, but we know of no previous instance of a voluntary termination resulting in a saving to the proprietors, and it is this which stamps the Liverpool Overhead Railway as a thorough success.

We print this week the second half of the Paper by Rössler and Wedding on alternate-current arcs. It is, perhaps, somewhat unfortunate that an attempt has been made by means of a reflector to imitate the distribution of candle-power of a continuous-current arc. Curves similar to those which we reproduce from the magnificent book issued by the Helios Company would be more instructive, though the photometric work would be more than doubled. The photometrical results are considerably inferior to those of continuous-current arcs, and part of this deficiency must be

Digitized by Google

attributed to the use of the reflector. The alternate-current arc has its uses where light is wanted above as well as below, and it seems better to measure it under these favourable conditions. A good deal yet remains to be written about alternate-current arcs, and no doubt much remains to be investigated. While it seems clear that a flat-topped current curve gives most light, the hum which such a current produces is, quite possibly, principally the fault of the lamp. Nothing is said in this Paper about the cause of or cure for the violet band which encircles the globe of most alternate-current arcs, and but little information is given about the lag of phase or its cause, or how a lamp may be made to run off a machine for which it has not been adjusted. The Hefner unit employed in these photometric measurements is the amyl-acetate lamp, and is about 0·98 of an English candle-power.

A proposal to revive an abandoned electrical unit may seem strange, but we none the less think that there is room for the volt-ampere under certain conditions. In the tests of Helios arc lamps, which will be found in another column, no attention has been paid to the small lag between volts and current, which is produced by an arc. The elaborate tests of Rössler and Wedding take this displacement of phase into account, and in the portion of their Paper which we printed last week, it was given at about one-eighteenth of a half-period. Where the lag is neglected, the product of volts and amperes might be called volt-amperes as of old, and thus be distinguished from true watts. We have adopted this expression in our reprint of the Helios tests.

It would be decidedly instructive if one could ascertain the exact amount of influence which the diminutive premiums annually offered by the Société d'Encouragement pour l'Industrie Nationale actually have on the industrial development of France. The Grand Médaille à l'Effigie d'Ampère, which this same Society recently presented to Lord Kelvin in recognition of his life's labours, may very possibly encourage others to deserve a similar reward. But the premiums of the Société d'Encouragement appear to be quite distinct from its medals; the latter are, apparently, meant to be honorary recognitions of scientific work of great ultimate or immediate utility; the former are evidently intended to stimulate invention. Inventors, it is true, are, like the rest of mankind, stimulated by nothing so effectually as by hard cash; but what useful purpose can be served in offering a few thousand francs for the "complete solution" of problems, the complete solution of which would any time these last 10 years have made the fortunate solver rich beyond the dreams of avarice?

In the list of premiums offered by the Société d'Encouragement for the years 1895-96, we note, firstly, one of £80 for the "complete solution" of the problem of economically producing ozone on a commercial scale. Now, if ozone possesses one half the advantages claimed for it as a bleaching and disinfecting agent, an £80 stimulant is quite superfluous. Similar amounts are to be presented to any gentleman who can devise a method of rapidly measuring the insulation of an electric supply network, or who can invent a 1-candle, 100-volt, 5-watt glow lamp. The *pièce de résistance*, however, is the premium of £120 offered to the individual who by scientific chemical synthesis, by the method of empirical messes, by burrowing into the bowels of the earth, or by any other means whatsoever, discovers—a substitute for gutta-percha. We have no desire to raise undue hopes, but if the individual who solves *this* problem completely will approach, say, the Telegraph Construction and Maintenance Company, we venture to think that that £120 premium will vanish from the inventor's mind, if ever it were present there.

The announcement made by the *Western Electrician* that there is a possibility of the National Electric Light Association and the American Street Railway Association being before long combined, may be taken as a sign of the predominant position which the electric tramway business has assumed in the States. The National Electric Light Association is, it has always seemed to us, an organisation which might be reproduced with advantage in this country, since it is such a happy medium between the ultra-commerciality of the Electrical Trades' Section and the severe science of the Institution of Electrical Engineers. The probability of such an organisation being formed in England is, however, somewhat remote, and were anything of the kind brought into being, we are afraid it would have to hold its "conventions" with closed doors, as is the case in America, notwithstanding the plaintive wail of the technical journals, with the Association of Edison Illuminating Companies. If the general public, for instance, were allowed to become familiar with all the practical details of alternate-current distribution, all the mystery, and, therefore, half the attractiveness of that system would be gone.

There was some ambiguity in part of our article on "The Sine-Curve Controversy" last week. We contend, with Mr. Steinmetz, that the flat-topped curve of magnetism is better than the sine curve. This means a peaked curve of volts. Our American friends, on whose side Prof. H. J. Ryan places himself, prefer the sine curve. When they speak of a sine curve of volts they assume, of course, a sine curve of magnetism also.

Hampstead.—October 1st has been fixed as the date for the public "inauguration" of the electric light at Hampstead.

Cable Interruption:

	Date of Interruption.
Zanzibar-Mombasa	September 4th.

The Late Werner Siemens.—The monument to the late Werner Siemens is to be erected at the corner of the Markgrafen and the Lindenstrasse in Berlin.

The Royal College of Science, Dublin.—The autumn session of this college commences on October 1st. Courses of instruction in the sciences applicable to the industrial arts are provided. Further particulars with regard to fees, &c., will be in our advertisement columns.

Long Distance Telephony in Servia.—A telephone line has just been completed between Belgrade and Nisch. The line is 125 miles long. It is only intended for use between the Government authorities in Belgrade and the King, whose residence is at Nisch.

Telephonic Development in New England.—Great activity among the local telephone exchanges is reported from New England. A great number of the systems are being entirely

Digitized by Google

rebuilt, with new and heavy poles, new wire, and improved construction generally, while the number of trunk-lines between the principal business points is being largely increased.

Obituary.—The death is recorded of Mr. Charles Wood, Chief of the Mechanical Engineering Department at the Silvertown Works. Mr. Wood was only 55 years of age, but had done 23 years' useful work for the Silvertown Company. Whilst at Silvertown Mr. Wood was largely responsible for the construction of the Company's cable machinery and electric lighting machines.

The Budapest Electric Motor Exhibition.—The Exhibition of electrically-driven machine tools, which we announced some months ago as about to be held at Budapest, has resulted in the getting together of 32 alternate-current motors and 42 continuous-current motors driving printing-presses, saws, ventilating fans, sewing machines, and ice-making machines, as well as drills and lathes.

Exports of Telegraph Wire and Apparatus.—During July the value of these exports reached a total of no less than £303,483, exports during the corresponding months of 1893 and 1892 being, respectively, £77,305 and £25,906. The following figures show the exports during the first seven months of this year as compared with similar periods in 1893 and 1892:—1894, £1,187,224; 1893, £556,500; 1892, £701,741.

The Electric Light in Japan.—According to a correspondent of the *Engineer*, electric lighting is progressing fairly rapidly in Japan, and two new plants have recently been put down—one at Okayama, and one at Maebashi, the former having a steam plant, and the latter a water-wheel. Both these places are now important towns, and the authorities, in adopting the electric light, have only followed an example set by other towns of the same standing.

The American Post Office and Electric Tramcars.—The two new postal trolley cars for Brooklyn, whose trial trips took place recently, will, says the *Electrical Engineer* of New York, greatly facilitate the free mail deliveries in the suburbs recently annexed to Brooklyn. The mail bags will be received from the stations through an open window on each side of the car and deposited in the same manner. The cars are both lighted and heated by electricity.

A Brave Telegraphist.—Among the acts of heroism reported by the newspapers in connection with the American forest fires is that of a young telegraph operator named Thomas Dunn, who stood by his instrument, although the flames were fast surrounding him, in order to despatch a message ordering a train to proceed to Hinckley to convey 300 persons to a place of safety. He got his message through, and the people were saved, but he himself perished.

City and Guilds Programme.—Messrs. Whittaker and Co., of Paternoster-square, have just issued a programme of technological examinations of the City and Guilds of London Institute for the session 1894-95. The programme contains regulations for the registration and inspection of classes in technology and manual training, a syllabus of subjects, a list of prizes for 1895, a list of teachers of the registered classes, and the examination questions for 1894.

Asbestos.—It appears that, owing to the presence of impurities, certain kinds of asbestos possess marked magnetic qualities. Mr. A. A. Campbell Swinton writes to say that not only can asbestos millboard be lifted by a strong magnet, but the individual fibres of soft asbestos packing are affected. He finds it possible to permanently magnetise a piece of asbestos millboard. It is clear, therefore, that this material is not suitable for use in connection with delicate instruments.

Heriot-Watt College, Edinburgh.—It is announced that the session 1894-95 extends from Tuesday, October 9th next, to Friday, May 31, 1895. The classes are suitable for students who have previously passed through the curriculum of a secondary school, and include physics and chemistry, mechanical engineering, and electrical engineering. A calendar giving full particulars may be obtained from the librarian at the college, or from the treasurer, 20, York-place, Edinburgh.

Aberdeen.—The municipal electric light accounts, which have just been issued, show a net loss for the period dealt with (eight months) of £292. The total capital expenditure comes out at £21,061. The working expenses for the eight months under review amounted to £289, the revenue coming short of this by £52. The total quantity of electricity generated was 9,833 units, of which 1,589 was used by public lighting, 6,581 by private consumers, and 261 in the works, leaving 1,402 units, or 14 per cent., unaccounted for.

Scottish Scientists and American Reviewers.—Transatlantic reviews of technical books have until very recently always been cast in a uniformly eulogistic mould, but we do not recollect having ever before seen quite so complete an abnegation of his function as is evinced by the reviewer in the following:—"In treating of a work like this, criticism would be out of place, and the reviewer will have done his work if he conveys to the mind of the reader a correct idea of the scope of the book. This can best be done by repeating the table of contents." The work which is here considered beyond criticism is Vol. II. of Lord Kelvin's "Popular Lectures and Addresses."

Lightning Conductors.—An evening newspaper, given to answering all manner of absurd questions in an appropriately absurd manner, recently addressed the following reply to an inquiry *re* the efficacy of lightning conductors:—"The efficiency or otherwise of lightning conductors is scarcely a matter which comes within the range of the subjects ordinarily dealt with in this column under the head of 'Money Matters,' and we do not claim to have any special qualification for expressing an opinion. Take it for what it is worth, our impression is that lightning conductors properly fixed and properly dealt with, when carried into the earth, are not 'a source more of danger than safety.' If improperly fixed they may certainly be a source of great danger."

Terrestrial Magnetism.—At a recent meeting of the Vienna Academy of Science Herr J. Liznar read a Paper on the 26-day period of the earth's magnetism. In a previous communication the author had compared the diurnal variation at stations in middle and high latitudes. In the present Paper the magnitude of the 26-day period variation for declination and inclination at the stations of Pulowsk and Jan Mayen were compared, and it was shown that the amplitude of the variation at the northern station is four times as great as at the southern. The author also considers that the small variations which constitute the 26-day period variation are not due to a direct magnetic action of the sun, but that they must have their origin in some secondary action of the same.

Magnetic Nomenclature.—In advocating the use of iron wire on the armatures of small dynamos, an esteemed New York contemporary is enabled to pen the following convincing sentence, which should be read and re-read by all who wish to be abreast of the very latest nomenclature developments:—"It is certain that the winding of an armature with iron wire will materially reduce the reluctance of the gaps, and, therefore, will economise in exciting power, for two reasons: First, directly, by lessening the total reluctance of the magnetic circuit, of which the air gap is the most prominent portion; and, second, indirectly, by reducing the magnetic leakage of the machine, which is the quotient of the sum of the permeances of the stray paths by the permeance of the useful path, the latter being practically equal to the reciprocal of the reluctance of the gap spaces."

The Future of the Oil Engine—The *Engineer* is of the opinion that we are probably destined to see in a comparatively short time a great development in the construction and use of the oil engine, and the rapid progress of the past year or so warrants the belief that another year will witness equally great strides. The oil engine offers so many advantages for small powers and for portable and traction purposes, that even an increase in the price of oil will not much decrease its rapidly extending application. The fact that it needs no boiler, no fire, no gas holders, and very little water, and that its fuel can be bought everywhere, must make it the future motor for very many purposes, not excepting launches. The objections with respect to smell will gradually pass away with the improvements which will make the engine as clean as a corporation water works pumping engine, and as free from offensive smell.

The Indo-Chinese Land Line.—For some time, says the *Pioneer*, negotiations have been in progress with China to secure the linking-up of the telegraph lines which have their termini in the Bhamo district and Yun-nan respectively. The Indian system has approached within a few miles of the extreme western frontier of China, while the Chinese wires have been carried well into Yun-nan. There is probably a gap of less than two hundred miles between the stations, and this could be bridged over in a few months if the Pekin Government and the Foreign Office came to an agreement on the point. Then there would be overland communication between India and China, and the cost of telegraph messages between the two countries would be considerably reduced. Both from a commercial and a political point of view it is most desirable that this through line should be completed ; but there is likely to be further delay now that China has her hands full with the war in the Corea.

Gas-Motor Cars in Chicago.—According to Mr. Roach, superintendent of the North Chicago Street Railway Company, gas-engine cars have there been found impracticable for street railway service. Speaking of his company's experience, Mr. Roach said: "Gas engines are all right in theory, but they are away behind the times. Our Company has spent $75,000 in buying, building, and improving gas motors, all to no purpose. It now has gas motors to sell. They made too much noise. The link-belt machinery and the exhaust of the engine was too much for even the Chicago public. So we took the motors off of the cross lines, where we were using them, and employed horses again." The Company's experience with steam motors was equally unsatisfactory, and finally it was determined to discontinue experiments in this line. Several types of storage batteries were also tried, but these were not adapted to the heavy business of the lines. The Company is at present wedded to the cable and horse systems.

Prof. von Helmholtz.—The following paragraph, which appeared in the *National Zeitung* of Friday last, and which we have good reason for believing to be absolutely correct, will reassure all those who have heard with concern of the recent severe illness of Prof. von Helmholtz :—To-day Hermann von Helmholtz completes his 73rd year. But the rejoicing natural on such an occasion will be sadly diminished owing to the severe illness which has struck down the aged *savant*. However, already the worst fears of the first weeks may be dismissed, for the general condition of the patient has of late so far improved that he once more follows with lively interest the progress of the work of the Physical-Technical Institute, over which he presides. The paralytic symptoms also have so far disappeared that remedial measures have been begun under the skilful superintendence of Prof. Renvers and Dr. Kirchhoff. There are good grounds for hoping that Herr von Helmholtz will before long resume his place as active head of the Reichsanstalt. May this anticipation be fulfilled, and his powers remain at the disposal of science for a long time yet.

High Speed v. Slow Speed Engines.—In a Paper recently read before the Iron and Steel Institute, Mr. D. Selby-Bigge gives some interesting figures relating to the performances of a 500-H.P. slow-speed horizontal compound condensing Van der Kerchove and a 300-H.P. Willans engine. The former runs at 66 revolutions, and drives direct on to a 20-pole fly-wheel Pieper continuous-current dynamo ; the latter runs at 350 revolutions, and is also coupled direct to a Pieper dynamo ; both combinations are at work at the National Arms Factory at Herstal, near Liége. The efficiency of the Van der Kerchove combination at full load is about 77 per cent., the dry steam consumption of the engine per I.H.P. per hour = 14·34lb., and the dry steam consumption of the engine per E.H.P. per hour = 18·75lb. On the other hand, the highest efficiency is got from the quick running plant. The efficiency of the Willans engine and the Pieper dynamo combined at full load is about 85 per cent., the dry steam consumption per I.H.P. per hour = 15·41b., and the dry steam consumption per E.H.P. per hour = 18·19lb.

Electroplating on a Large Scale.—Perhaps the largest piece of electroplating ever carried out is that which is being done in regard to the protection from rust of the iron and steel structure of the tower of the new City Hall of Philadelphia, now in process of erection and nearly completed. This work is being carried out by the Tacony Iron and Metal Company. It is a double process ; the object of the first stage being the protection of the metal from rust by electroplating it with copper to a weight of 14oz. per square foot of surface, and the finish being an electroplate coat of an alloy of aluminium and tin weighing 2½oz. per square foot—the purpose of this being to give colour, and also to prevent oxidation of the copper into a green skin of verdigris. The plan was adopted in preference to paint, on the score that the periodical renewals of the latter would cost £2,000 per annum. The total weight of wrought and cast iron to be protected is about 500 tons, extending to 100,000 square feet of surface. This process is, in effect, an attempt to remove the reproach of perishableness from structural iron and steel, and to make these materials last for ever without further protectionary measures of any kind.

Solar Electrical Energy.—According to Dr. M. A. Veeder (*Proceedings* of the Rochester Academy of Sciences, Vol. II., July, 1894), there is conclusive evidence that magnetic perturbations are not of thermo-electric origin, and are not connected with heat and light radiations. He holds, in short, says *Nature*, that there is no correspondence whatever between the behaviour of magnetic storms and the manner in which thermal and luminous radiations are originated and propagated from the sun to the earth. His idea is that electrical disturbances upon the sun are transmitted to the earth not by radiation but by conduction through the impalpable dust and *débris* with which interplanetary space is filled. Such meteoritic particles are composed of good conducting material, and an examination of a large number of meteorites has shown Dr. Veeder that they all possess magnetic properties which might have been produced by long-continued induction. Therefore he thinks that the origin of magnetic storms is as follows :—"Particular portions of the sun's surface and cooler immediate surroundings are electrified by what has every mark of being volcanic action. The motion of rotation of the sun carrying forward these charged portions of its surface, develops currents dynamically which act inductively along lines of force wherever there is conducting material within their scope. There is no conveyance by radiation or in a manner similar to that in which heat and light are conveyed from the sun. The laws governing the process are entirely different from those of radiation, and have reference to the principles of conduction as they appear under the conditions existing in interplanetary space. It is a mode of solar action that is distinct, and that must be considered by itself."

A War Balloon Struck by Lightning.—An alarming accident, happily not attended with fatal results, occurred on Wednesday afternoon at the Aldershot School of Military Ballooning. A new balloon, larger than any of its predecessors, was to have been "christened" by the Duchess of Connaught. This balloon had been inflated during the morning, and stood ready. It had been arranged that the Duchess was to cut the rope retaining the balloon, and that Lieut. Baden-Powell, of the Scots Guards, and two sergeants of Royal Engineers were to make a free ascent. The "Flo," the smallest military balloon, containing 4,700 cubic ft. of gas, was also inflated and bore a large Royal Standard. As soon as the Duke and Duchess of Connaught and staff arrived on the ground, this smaller balloon was sent up captive as a Royal salute. Lieut. Blakeney had intended to ascend in it ; but, as at this moment a strong wind arose, it was decided to send up the balloon without anyone in the car. As the rain began to descend more heavily the party repaired to the storehouse, and very shortly afterwards the accident happened. The balloon was held by a wire cable about 200ft. long, fixed to the drum on the balloon waggon. Suddenly it was seen to be struck by lightning, flare up and collapse. Loud shouts from the sappers forming the detachment at the waggon attracted attention, when it was seen that three of them were rolling on the ground, apparently in intense pain. It seems that the men were about to haul the balloon down by winding on the winch, the handles of which are covered with brass, when suddenly all who had hold of the winch were struck down. Every assistance was immediately rendered to the injured men. It was soon seen that, though evidently in great agony, none of the sufferers were very seriously injured.

THE EFFICIENCIES OF GLOW-LAMPS.

An electric glow lamp is a machine for transforming energy from one form, viz., the energy of an electric current, into another form, viz., eye-affecting radiation. As explained in my first Lecture, it transforms the electric energy into radiant energy, or energy of ether waves, only a fraction of which can impress the eye as light. This fraction varies from 3 to 7 per cent. This numerical expression for the "luminous efficiency" can be determined by suitable experiments in which the relative amounts of luminous and dark heat sent out by a glow lamp are separately measured. If a glow lamp **L** (*see* Fig. 1) is immersed in water in a transparent vessel **V** the water absorbs or stops nearly all the dark or non-luminous radiation, but permits a large fraction of the luminous radiation or light to pass out. By photometering the lamp both when in and when out of the water the fraction of the luminous radiation which is absorbed can be determined. By measuring the rise of temperature of the water which is created by the absorption of the radiation, both when the luminous radiation is allowed to pass out and when it is wholly stopped by blackening the lamp, we can determine the ratio between the amount of the radiation which affects the eye as light and that which cannot affect it at all. A well-devised series of experiments of this kind have been carried out by Mr. E. Merritt, at Cornell University, U.S.A. The result has been to show that, on an average, about 5 per cent. of the energy supplied to the

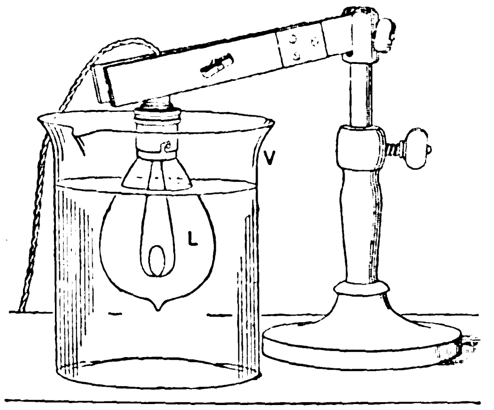

Fig. 1.—Glow Lamp Burning under Water.

glow lamp as ordinarily used is utilized to make light, and the other 95 per cent. is non-effective as far as the eye is concerned. Hence, if a glow lamp is supplied with 60 watts and gives 16 candles light, only 3 watts are really transformed into light, and the mechanical value of the light so produced is rather less than a quarter of a watt per candle.

This luminous efficiency varies with the temperature of the filament. At a low red heat it is not more than 1 per cent., but increases to about 5, 6, or 7 per cent. at the normal working temperature. Thus, for an Edison 16-c.p. lamp Mr. Merritt found the following figures when the lamp was worked at various pressures so as to give different candle-power.

It will be seen that the luminous efficiency increases as the "watts per candle-power" decreases—that is, as the temperature of the filament increases.

The "luminous efficiency" must be carefully distinguished from that which is sometimes called "the efficiency" of the lamp, and which is the reciprocal of the watts per candle or the number of candles light yielded per horse-power or per watt expended in the filament.

It will be convenient for me at this stage to enter a little more fully into the changes that go on in an incandescent electric lamp during its life. We have pointed out above the causes which are at work to change the surface and ultimately to destroy the carbon filament. These causes com-

Luminous Efficiency of a 16-c.p. Edison Glow Lamp.

mence to act from the very moment when the lamp begins to be used. If a carbon filament electric glow lamp is placed upon a circuit of perfectly constant pressure, and if the constants of the lamp—namely, the candle-power, the current, the resistance of the filament, the power taken up in watts, and the watts per candle-power—are measured at intervals, say of every 100 hours, it will be found that the changes which go

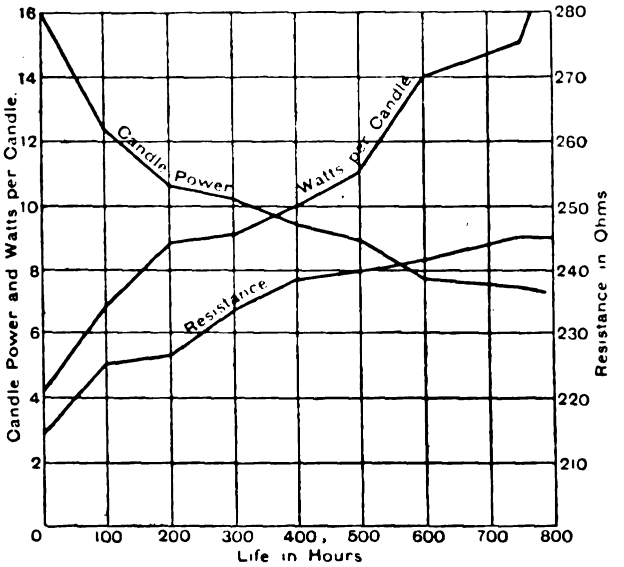

Fig. 2.—Curves showing the increasing resistance and diminishing candle-power of a Glow Lamp during its life.

on in the lamp are somewhat as follows:—During the life of the lamp there is a progressive rise in resistance, a progressive diminution in candle-power, and a progressive increase in watts per candle-power. An illustration of these changes is diagrammatically shown for certain forms of ordinary vacuum lamps by the curves given in Fig. 2. These curves are deduced,* not from observations on one lamp alone, but from the average of a large number. If, instead of working the lamp at its marked volts or normal pressure, we raise the voltage, say, 10 per cent. above the normal, changes of the same character take place, only they are very much accelerated, and the result for a collection of lamps worked at 10 per cent. above the normal pressure is given in Fig. 3. On the other hand, if we desire to keep the candle-power always constant, we have to continually raise the pressure, and at the same time we are increasing the watts per candle and the resistance of the lamp. These progressive changes are illustrated in the two curves in Figs. 4 and 5, in the first of which a 16-c.p. lamp was worked at continually-increasing pressures sufficient to keep the candle-power always constant, and in the second of which the candle-power was raised to four times its normal value and kept constant.

The value of a lamp to a user is not to be measured merely by the watts per candle-power it takes at the commencement of its life, but also, to a large degree, by the extent to which this consumption of energy and production of light remains

* From a forthcoming work on "Electric Lamps and Electric Lighting," by Dr. J. A. Fleming, to be published by *The Electrician* Printing and Publishing Company. All rights in text and illustrations are reserved.

* These curves are borrowed from a very instructive Paper by Prof. Nichols, of Cornell University, U.S.A., on "The Artificial Light of the Future."

Digitized by Google

constant during the life of the lamp. This is best expressed by the percentage of the variation of the candle-power during the life of the lamp when taken at equal intervals of time. A 16-c.p. glow lamp, taking say 60 watts at the commencement of its life, but which after two or three hundred hours in use is giving no more than 8 candles light, although taking the same power, is costing the consumer twice as much per candle at the end of this time as at the beginning. Some

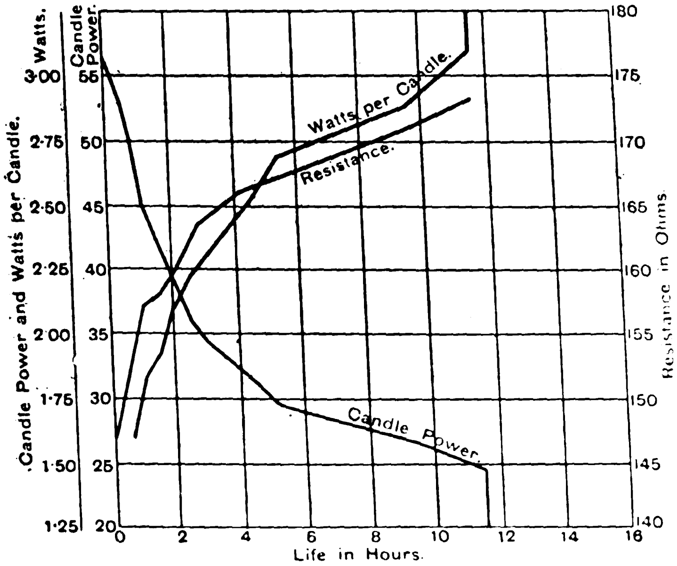

FIG. 3.—Curves showing the rapid decrease in candle-power and increase in resistance in a Glow Lamp worked at 10 per cent. above its normal pressure.

writers have, therefore, suggested that at the end of a certain period, when the candle-power has suffered a definite diminution in value, say, of more than 30 per cent., the lamp should be "smashed," and a new lamp put in its place. This, however, is not always advisable or necessary. If the lamp in the position in which it is being used is giving light enough for the purpose for which it is required, then, although its candle-power may be diminished, if the total

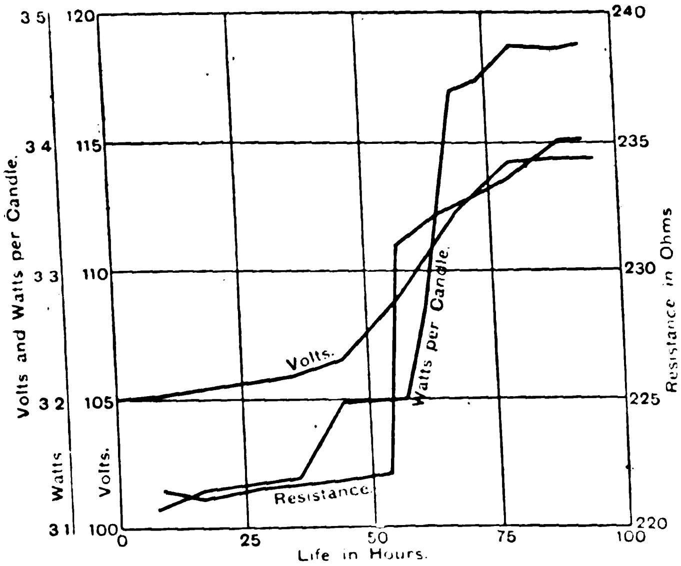

FIG. 4.—Curves showing the increase in Voltage required to keep the candle-power of a Glow Lamp constant.

power taken by the lamp is diminished also, the total sum which is being paid by the consumer for the energy supplied to that lamp is on the whole diminished, and therefore the lamp is costing the consumer less *on the whole* to maintain in action than a new lamp would do if it replaced the old one, although at the same time the cost of the lamp per candle-light may be considerably increased. Generally speaking, users of electric glow lamps have an idea that the lamp which lasts the longest is necessarily the best. From what has been stated above, it will be seen that it is not merely long life, but constancy of candle-power, combined with high luminous efficiency and low cost, which are really the factors determining the value of the lamp to the consumer. The duration of the lamp is intimately connected, apart from accidents, with the temperature at which the carbon filament is maintained, and this is determined by the watts per candle-power being expended in the lamp. Makers of glow lamps sometimes make statements which lead the uninitiated to believe that there is a certain "efficiency" or peculiarly low value of the watts per candle-power belonging especially to a certain make of lamp. It should be, however, clearly understood that any glow lamp may be worked at values of the watts per candle-power varying over very wide limits, but experience has shown that carbon filaments, as at present made, cannot be worked at temperatures higher than those corresponding to about 2 to 2½ watts per candle-power without very rapidly being destroyed.

A number of tests have been made by Messrs. Siemens and Halske on lamps of various types, and in which groups of these lamps were worked at different watts per candle-power from 2 to 4 and upwards. The lamps were measured at intervals of 100 hours, and the diminution in the observed

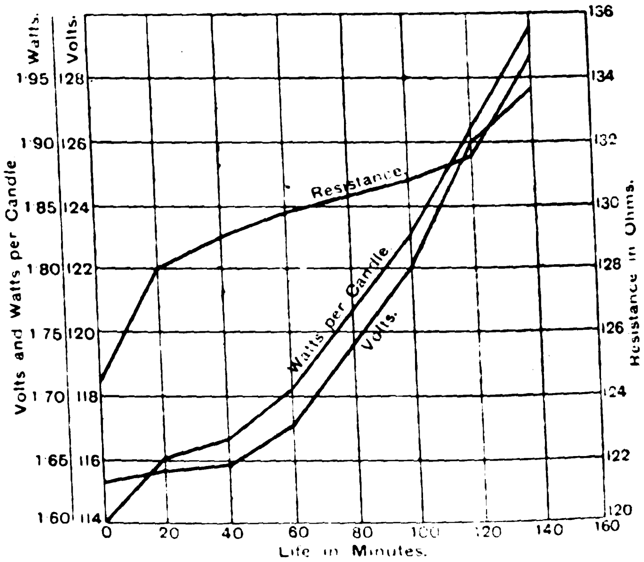

FIG. 5.—Curves showing the increasing Voltage necessary to keep the candle-power of a Glow Lamp constant and equal to four times its normal amount.

candle-power expressed as a percentage of the original candle-power was laid down in the form of curves. The results of these tests seemed to show that, on the whole, lamps worked at from 3 to 3½ watts per candle-power had a greater average constancy in candle-power than those worked at a lower number of watts per candle-power. That is to say, if we take a 16-c.p. glow lamp and work its filament at such a temperature that it is taking on the whole 32 watts, or 2 watts per candle-power, it may take less power to begin with, but it will not preserve nearly the same constancy of candle-power as if it had been worked at such a temperature that it absorbed from 48 to 56 watts at the commencement of its career; in other words, absorbed 3 to 3½ watts per candle-power. No hard and fast rule, however, can be laid down about these matters. No deductions can be made which have any great value from tests made upon a very small number of lamps. As I have previously stated, the lives of electric lamps are in this respect like human lives, and just as the insurance companies have to draw their deductions and to make their calculations for life insurance on the results of figures obtained from a very large number of human lives, so inferences made from the results of statistical tests carried out on incandescent lamps are only of use if they are made on a very large number of lamps. Broadly speaking, however, the duration

Digitized by Google

of an incandescent lamp is dependent upon the electric pressure at which the lamp is worked, and if a lamp is marked to be used on a 100-volt circuit, then if it is used on a circuit at a pressure of 105 volts, its life would be greatly abbreviated, probably to one quarter or one fifth of the time which it would last if worked at the normal pressure. On the other hand, if it is worked at a pressure of 95 volts, its duration, accidents apart, will be very greatly increased. It is useful, therefore, to have, under these circumstances, a general knowledge of what would be the variation in candle-power if the same lamp is employed at different voltages. The tables on the next page give the candle-power yielded by two particular electric glow lamps when worked at varying pressures, the first table being for a 100-volt 16-c.p. lamp, and the second table being for a 100-volt 8-c.p. lamp. A very cursory examination of these tables will show that the light given by the lamp varies enormously with the pressure, and that a very small diminution of pressure suffices to deprive the user of a very large fraction of the candle-power for which the lamp is constructed.

THE POTENTIAL AND CURRENT CURVES OF DIFFERENT TYPES OF ALTERNATORS, AND THEIR INFLUENCE ON THE CANDLE-POWER OF ALTERNATE-CURRENT ARCS.*

BY G. RÖSSLER AND W. WEDDING.

(*Concluded from page 526.*)

Part II.—Photometrical.

The lamp, as above described, was run with 10 amperes, and carried close above the arc the universally-employed white enamelled reflector, thus lighting only the space below it. The lamp was carefully regulated for each machine, and it was found possible, after some practice, to regulate with such accuracy that the maximum deviations were not more than 0·3 volt. That pressure was chosen for the measurements which kept the lamp in the most stable condition, the observations being always made at the same pressure, which kept very constant, and which varied on different days and for different machines from 28·8—31·1 volts. In order to attain an even consumption of the carbon during each set of observations each was begun after running the lamp for two hours, and the carbons used were cored carbons of the Siemens A type, 10mm. thick.

The photometric arrangements were those usual in the Berlin Electro-technical Laboratory. As comparison, a glow-lamp was used on each side, run at high efficiency to make it as white as possible, and whose pressure was controlled by a Weston voltmeter. After each set of observations the candle-power of each lamp was tested by comparison with a Hefner lamp. In order to determine as accurately as possible the distribution of illumination in two adjacent quadrants lying under the horizontal plane, about 17 observations for each quadrant, the angles being taken close together at about 45°, and further apart at the horizontal and vertical planes, and 6—12 observations were made on each photometer for each angle.

In circuit with the arc lamp was an inductionless resistance, on which, by means of an electrometer, the pressure for the determination of the current curve was read, a regulating resistance for the lamp, an ammeter by Schuckert, a Thomson balance to standardise it by, a Helios wattmeter, and a Cardew voltmeter. This last was on the terminals of the lamp, and in parallel with it the pressure coil of the wattmeter, also a connection for determination by the electrometer of the pressure curve (see Fig. 7). The standardisation of the voltmeter was done by the electrometer, of the ammeter by the Thomson balance, and of the wattmeter by both; and as ultimate standard the well-known compensation apparatus of the Reichsanstalt. It was found that the Schuckert ammeter readings had to be multiplied by 1·311 for the Ganz machine, with 40 volts; with the Wechsler machine the factor fell to 1·018, and for the Siemens to 1·013.

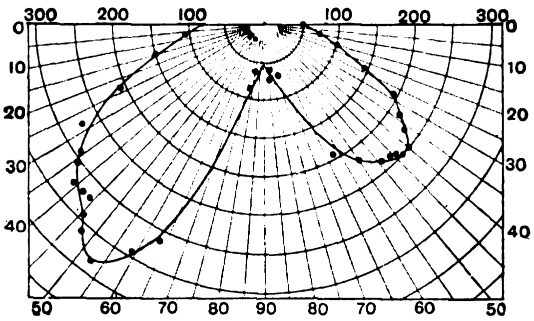

Fig. 12.

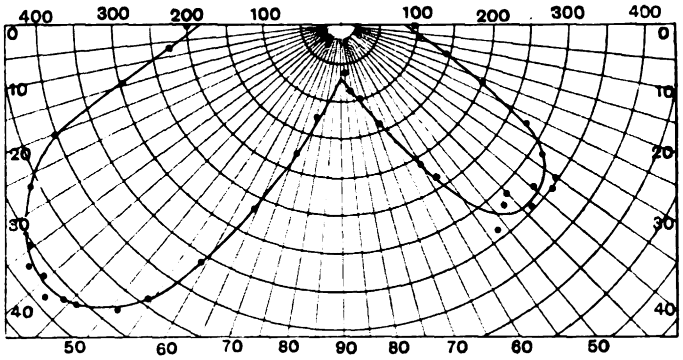

Fig. 13.

There are nine sets of observations for the Ganz machine, Table IV. gives the complete values for the various angles of one of these sets. The figures are the mean of from 6—10 observations.

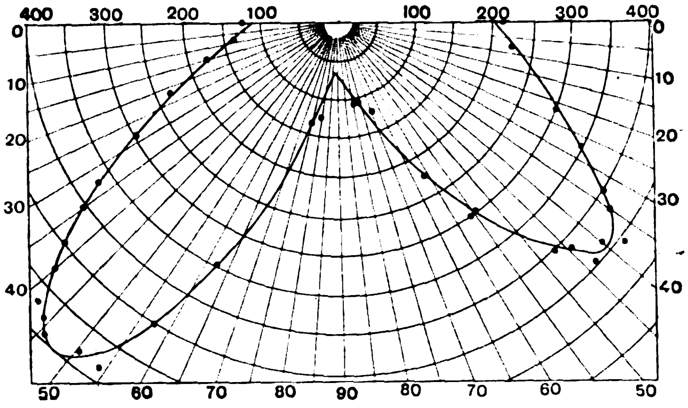

Fig. 14.

In the first three columns we find the electric quantities, allowing for the energy consumed in the instruments. The next four columns give us the photometrical measurements for each angle, which were made in pairs in the opposite quadrants. The last column shows the mean spherical intensity under the horizontal reduced to one watt between the lamp terminals as found by the usual geometrical construction. The variations occurring in the measurements of the candle-power between 30°—60°, are due partly to the reflector and partly to uneven consumption of the carbons.

Wechsler..................	0·906	0·906	0·90	0·907
	0·906		0·914	
Siemens and Halske ...	0·897		0·911	

The reflector is not to be regarded as a perfect mirror, and the carbons are, of course, not perfectly uniform. These variations are only photometrically observable, and are not of practical importance. The curve derived from these observations is given in Fig. 12. The spherical intensity is calculated for each direction, and the mean of these two values taken.

In the next Table are the results of the Wechsler machine, to which Fig. 13 is the curve. The mean spherical intensity has risen from 0·716 to 1·003 Hefner units per watt. The next Table gives the same curve for the Siemens machine, with Fig. 14 as its curve. The spherical intensity is here 1·078 H.U. In Table VII. is given a summary of all the experiments made on the machine.

It is seen from these results that the development of light does not perfectly follow the sharp ascents and descents of the curve of E.M.F. given by the Ganz machine, and, consequently, the energy is not fully utilised. Smoothing out the curve, as in the Wechsler, immediately increases the light given per watt by 44 per cent. ; or, put more vividly, if the Ganz machine were replaced by a Wechsler, one in every three lamps might be removed for the same illumination.

The third machine, that of Siemens and Halske, could only give the required volts at a higher frequency. When the frequency is raised 33 per cent. the light rises about 6 per cent. It is not impossible that the light evolved rises with the frequency, and Blondel holds it for certain, but our experiments do not furnish any very clear evidence one way or the other. On the other hand the observations on the third machine also show the same kind of difference in intensity of illumination when compared with the first.

From the form of the curves certain important conclusions may be drawn with regard to the illuminating power of arc lamps. If we take the ratio of the simple mean current M(J) to the value measured $\sqrt{M(J^2)}$, and similarly for the E.M.F., we find

	$\frac{M(E)}{\sqrt{M(E^2)}}$		$\frac{M(J)}{\sqrt{M(J^2)}}$
Ganz and Co	0·783	....	0·656
Wechsler.....................	0·906	....	0·907
Siemens	0·897	....	0·911

For a true sine curve the value should be 0·900. Since the value 0·907 differs by 28 per cent. from 0·656, and the photometrical measurements, which cannot be made with the same accuracy, give a ratio of 30 per cent., we may consider these as equivalent. There is thus ground for the conclusion that the development of light of an alternate current arc lamp is proportional to the simple mean value of the current.

If we try to make $M(J)/\sqrt{M(J^2)}=1$, then the current curve must have the shape shown in Fig. 15, which approaches that of the Siemens machine ; and the extra illuminating power may be partly due to this, as well as to the increased frequency ; unfortunately there is only one curve to be dealt with, giving the value $M(J)/\sqrt{M(J^2)}=0{\cdot}911$, and for the photometric observations there are only two sets, giving a value of 1·110, so that no definite conclusion can be drawn. But falling back on the first two results, we see that if the light varies as the simple mean value of the current, the quantity of light should rise from 1·024 to 1·13 ; and the lamp would give for a current maximum of 10 A a quantity equal to 1·13. Apparently it would be best to build machines whose curves approach the shape of Fig. 15.

There is, however, an objection to the universal use of such curves ; for if we take into consideration other phenomena we find that while with the Ganz machine the ordinary hum of the arc is increased to a rattle so loud as to make its use impossible in a room, the Siemens machine only makes an ordinary, but loud, humming, while the Wechsler machine makes the lamp burn almost silently. The same phenomena occurred with a Helios lamp. Taking this into consideration, we see that the sine wave gives the best results ; the development of light is fair, and the arc is silent.

In conclusion, we draw a comparison between the amount of light developed on direct and alternating currents. The experiment was made with a Siemens differential lamp, using a cored carbon 10mm. in diameter and a homogeneous one 3mm. The method and arrangement were as before, the current being supplied by accumulators :—

Mean volts in lamp.	Mean current in lamp.	Mean watts in lamp.	Mean spherical intensity under horizontal per watt.	Mean.
46·85	9·26	433·8	2·80	2·84
46·85	9·29	435·2	2·90	
46·85	9·25	433·4	2·82	

We have an average value of 2·84 H. U. per watt, which is very high, partly because of the very small lower carbon, and secondly, because we are dealing with higher amounts of power. If we avoid this by taking a case of a lamp of about the same power, as taken

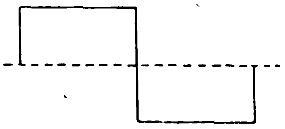

Fig. 15.

from the Table on page 149 of Herr Heim's book, "Die Einrichtung Elektrischer Anlagen," we should have a value of 2·64 H. U. per watt. It is, therefore, evident that for a given consumption of energy the illuminating power of a direct current arc is considerably higher than that of one run by an alternate current. This result confirms that already published as the results of experiments at Frankfort. A large part of this unfavourable result is due to the reflectors, which only reflect about 70 per cent. of the light evolved ; and there lies here some room for improvement.

If we put in series on a 110-volt circuit two of these direct current arcs taking 6·8 amperes at 42·4 volts ; and, on the other hand, with an alternate current circuit at the same pressure, use four alternate current arc lamps, we have the following output of light :

The direct current has an energy of 748 watts, of which $2\times288\cdot3=577$ watts are used in the lamps, and 171 in the resistances, and the light evolved is $577\times2{\cdot}65=1528$ H. U. mean spherical intensity under the horizontal.

With alternate current arcs taking 9·42 A., and using about the same power, all the energy is used for production of light, and with a sine curve (using Table IV.) we produce

$$4\times286{\cdot}8\times1{\cdot}024=1175 \text{ H. V.}$$

mean spherical intensity under the horizontal. Thus this arrangement also is more efficient with direct than with alternating currents.

Electrical Standards.—The British Association Committee appointed to conduct experiments for improving the construction of practical standards for electrical measurements, reported at Oxford that the work of testing resistance coils at the Cavendish Laboratory had been continued, a list of 43 coils tested being given. The report comprises several appendices, amongst others being those relating to experiments on the value of the ohm, by Prof. J. Viriamu Jones, and a comparison of some of the standards of the Board of Trade with those of the Association, by Mr. Rennie. The Committee report that the insulation of some of the coils referred to in their last report, which had been selected for the new standards of resistance as defined by the resolutions adopted at Edinburgh, had proved defective. The insulation of some of the other standard-ohm coils was also stated not to be satisfactory. In consequence of the difficulty met with in the insulation of some of the coils, it has been thought well to defer the purchase of other coils for which the grant of £25 was obtained last year. The Committee were of opinion that it was desirable to complete their set of standards by obtaining from Germany certified copies of the standards of the Reichsanstalt.

STEEL-PLATE PORTRAITS

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; and Dr. Heinrich Hertz, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar of Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

REFLECTORS AND REFLECTION.

The elementary idea of the business of an electric light engineer is to sell a dynamo, some lamps, switches, wire, and perhaps a steam engine, and to erect the plant and set it running. The result to the customer is that he gets some light, and if all goes well the engineer gets paid. A conscientious engineer will take care that the lamps are of good quality; he probably does not make them, but buys them. He takes care that the wire shall be of at least 98 per cent. conductivity, and of sufficient size to carry the current without appreciable drop of volts. Perhaps he makes the dynamo, and he justly prides himself on an efficiency well into the nineties. He may, if he is fastidious, see that the diagram taken from the engine has a sharp cut-off; all these little one or two per cents, he will tell you, go to make up an efficient and economical plant. The steam engine runs well, the dynamo works cool and without sparking, the wiring is in accordance with all regulations, and the lamps are up to candle-power. Nothing more can be done, the engineer and his customer are satisfied, and there is an end of it. If someone then tells the engineer that, by a simple and perhaps inexpensive improvement, the illumination would be increased 10 or 15 per cent., or that an equivalent saving of fuel might be effected, some attention might be given to it; but if the customer became convinced that by a simple and perhaps inexpensive improvement his light might be doubled, trebled, or more, he would surely blame the engineer for having neglected it.

Dr. SUMPNER has measured the reflecting power of white paper and other dull reflectors, and, in an article contributed by him to *The Electrician*, in February last year, he showed that when the reflecting power of the walls of a room is 50 per cent., the effect of the successive reflection doubles the illumination; and if walls and ceilings were well whitewashed the light would be increased fivefold. The engineer would probably excuse himself by saying that his work begins at the boiler or dynamo, and ends at the lamp; that he is not a painter or decorator; and that his customer can do what he pleases about whitewashing. Reflectors are to be found in his

Digitized by Google

price list, and will be "extras." He might further add that no book on electric lighting, on physics, or on photometry discusses the subject of diffused reflectors, or the reflecting power of dull surfaces, and that he, therefore, has not committed any fault in neglecting to recommend this improvement. Nevertheless, he would do well, we think, to regard a reflector as an actual source of light, and a very cheap one, too. If it is the business of an electric light engineer merely to sell dynamos and lamps, there is no more to be said; but it is his business to provide *light*, it is his duty to attend to the use of reflectors and reflection.

The summation of fractional series which Dr. Sumpner discussed gives very remarkable results when the reflecting power is 50 per cent. or more; but with a reflecting power of 20, which may perhaps be obtained from brick or stone outside walls of houses, the reflection will add only about 25 per cent. to the original source of light, and it is to be observed that where there is no ceiling—that is to say, in open spaces—the useful reflected light is very much less. Though the reflecting power of dull surfaces is, indeed, a true reflection and not as has been asserted, a mere diffusion, whatever that may mean, the reflected light leaves the surface in all directions. It is easy to produce a dull white surface in which no visible trace of direct reflection can be detected, even at high angles of incidence; but even with ordinary surfaces of stone and paint the direct reflection may be disregarded. Any direct reflection—as, for example, from the higher windows of houses—in street lighting means an entire waste of light, for the light is reflected skywards, and about one-half of the whole diffused reflected light is thus wasted. If, then, an addition of only 25 per cent. could be gained by yellowish walls and ceiling, the gain due to house fronts in an open street would be almost imperceptible.

The natural and direct distribution of light by continuous current arcs on fairly high pillars is excellent, and reflectors are of no use whatever in connection with them. Now, while this is excellently adapted for the lighting of open spaces where illumination on the ground is the chief consideration, there are not a few cases in which light is required on walls, or for purposes of diffusion by reflection on ceilings. In such cases it seems that alternate-current arcs would be very useful. It is clear that where the walls or other surroundings have but poor reflecting power, it is useless to cast light on them for the purpose of general illumination. Where no surroundings exist—as, for example, on one side of a sea-front or "marine parade"—it is difficult for anyone but an alternate-current enthusiast to see the sense of throwing a large proportion of the light upwards to the sky. The walls of railway stations and the façades of houses in most towns are not as a rule good reflectors, and it is, therefore, in general, useless to illuminate them, unless, perhaps, in some parts of Aberdeen, Nottingham, and Paris, where light-coloured stone or plenty of white paint is used.

Hitherto we have discussed the actual photometrical value of the illumination, but that is not the ultimate object of street lighting. Partly on account of circumstances connected with the contraction of the iris of the eye, to which we have recently alluded, and partly on account of the perfectly general desideratum of a pleasant bright appearance, the lighting of house frontages is, no doubt, useful. A comparison between two streets, one with a well distributed illumination of, say, three candle-feet, on the ground, with continuous current arcs, sending but little light on to the houses; and another with only two candle-feet on the street, and one candle-foot or so on the houses, would probably result in a verdict in favour of the latter: not because it would be more usefully lighted, but because the effect would be more pleasant.

The alternate-current arc as usually employed sends as much light upwards as downwards, it is practically equivalent to two small continuous-current arcs, one being inverted. For ordinary street lighting, especially where the houses are of a dingy colour, the light from the lower carbon—that is to say, the light sent upwards—is of hardly any use at all. In interiors, of course, the conditions are very different; but not all alternate-current lamps are silent enough to use indoors. This question of loss and waste of light has led to the use of rectifiers, and the only drawback to this method is that it reverts from low-pressure distribution with arcs two in series on 100 volts, or four on 200 volts, or five in series on 230 volts, as at Brighton, and employs a considerable number of lamps in series, thus increasing the risk of breakdowns. An attempt has been made to save some of the waste light by reflectors, and if alternate currents must needs be used, these reflectors will no doubt prove of considerable service.

In view of the calculations of Dr. Sumpner of the increase of illumination due to the successive reflection of good white reflecting surfaces, engineers who profess to supply light cannot afford to neglect such valuable assistance. The Paper by Herr Wiener, which we reprint from *Wiedemann's Annalen*, is perhaps of more scientific than practical interest; but so little has been written on the subject that every contribution to our knowledge of the reflecting power of white surfaces is of importance.

THE ALTERNATE-CURRENT ARC.

Very little has been published about the alternate-current arc. It is well known that most good arc lamps may be made to run with alternate currents if the core of the main solenoid be laminated, and slight alterations made in the windings and weights; but very little is generally known about the behaviour of the arc. Among other very interesting matter which is to be found in the remarkable book recently issued by the Helios Company, of Cologne, is a brief account of some photometric tests of alternate-current arcs. We extract the following curves and tables relating to them.

Fig. 1 shows the distribution of candle-power of arcs of about the same current, viz., 10·5 and 11 amperes; but in the one case taking 28·5 volts and in the other 32·5 volts. With continuous current the higher volts would give a longer arc, and much more light would be emitted, simply by reducing the shadow of the negative carbon. But with alternate currents a very different and hitherto unexplained result is produced. An increase of 14 per cent. in the volts, and nearly 10 per cent. in the volt-amperes, is accompanied by a decrease of more than 15 per cent. in spherical candle-power. The outer curve shows the candle-power at 28·5 volts, and the inner curve at 32·5 volts. It will be noticed that the increase of volts has evidently lengthened the arc a little, for the candle-power at 50° below the horizon has been increased by about 50 per cent., and at 60° it has been more than doubled; but in the more horizontal directions it has been greatly reduced.

The next diagram shows the candle-power with different currents, the volts being in each case maintained at the best pressure for the particular current. In the table which follows the figure it will be noticed that the volts diminish from 30 to 25, while the current rises from 8 to 50 amperes. It seems from these curves that a 10-ampere arc is very inefficient, compared with the larger ones, but the descriptions accompanying the tests do not give much information about the carbons or other details of the experiments. The irregular shapes of the curves are no doubt due to the conscientious plotting of actual observations with no attempt at "smoothing." The average

Digitized by Google

shape probably resembles the well-known loop or oval of the continuous current candle-power diagram. There actually appears to be more light thrown skywards than on the ground with 50 amperes, but this may be accidental.

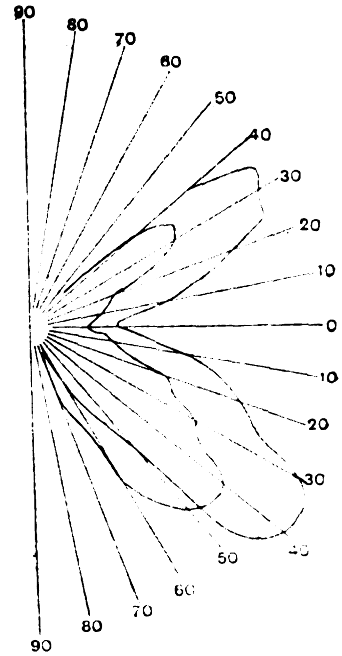

FIG. 1.—Curves showing the candle-power of an alternate-current arc measured at different inclinations with the horizon, and the reduction of candle-power produced by an increase of volts.

—	Volts.	Amps.	Volt-amperes.	Horizontal c.p.	Maximum c.p.	Sperical c.p.
Outer curve ...	28·5	11·0	313	150	550	275
Inner curve ...	32·5	10·5	343	93	423	205

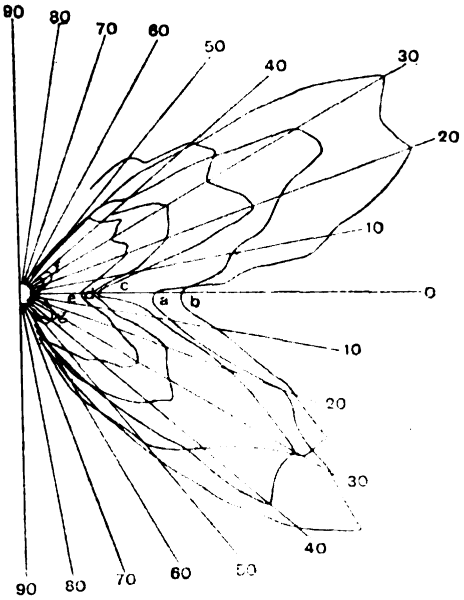

FIG. 2.—Curves showing relation of current to candle-power in an alternate-current arc.

Curve.	Current. Amperes.	Watts.	Volts.	Horizontal c.p.	Greatest c.p.	Spherical c.p.
a	50	1,250	25·0	1,630	4,840	2,625
b	30	825	28·0	1,800	3,880	2,200
c	20	500	27·5	940	3,760	1,500
d	16	468	28·0	925	2,160	1,200
e	15	413	27·5	670	1,570	870
f	10	313	28·0	150	550	275
g	8	250	30·0	92	530	250

The third diagram shows the remarkable effect of the Helios reflector. The inner curve is the candle-power without the reflector, the slightly reduced size of the upper dotted loop being, we suppose, accidental. The outer curve represents the distribution of candle-power with the reflector. This would show a very satisfactory result for a silvered reflector, whether of glass or of polished metal, but we were surprised to learn on

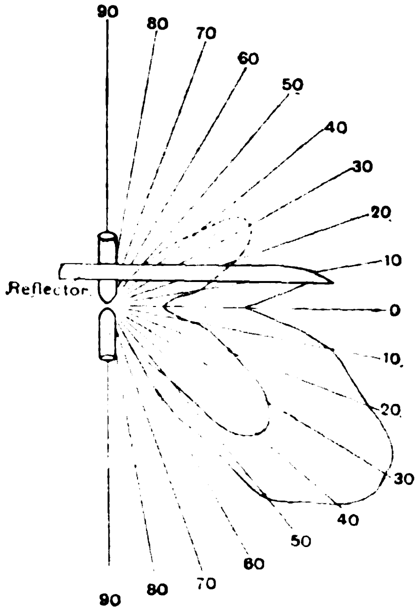

FIG. 3.—Candle-power of alternate-current arc, with and without reflector.

—	Lamp for	Consumption in watts.	Horizontal c.-p.	Greatest c.-p.	—
Inner curve	10 amp.	310	150	550	275 spherical c.-p.
Outer curve	10 amp.	310	372	912	498 hmisphricl c.-p.

making inquiries that it consists of a white enamelled iron disc with a slightly curved edge. Ten Helios lamps, with these reflectors, are being used at Newcastle for street lighting.

In connection with Mr. Dobson's Paper on workshop lighting by inverted arcs (see *The Electrician*, Vol. XXXI., Oct. 27, 1893, p. 701, we called attention to the necessity for arranging the reflector to subtend a large angle to the source of light. In order to carry out this condition and at the same time to avoid a large and clumsy reflector the Helios Company place it very close to the arc, and accurate focussing of the lamp is therefore necessary. A silvered reflector would soon be ruined by the heat if fixed in this position.

INTEGRATORS, HARMONIC ANALYSERS, AND INTEGRAPHS.*

BY PROF. O. HENRICI, F.R.S.

The first planimeter, properly so called, was invented by a Bavarian—Hermann—who, however, published no description of his instrument. A little later, Gonnella, of Florence, re-invented practically the same instrument; but, from the want of skilled labour in Italy, he was compelled to send his designs to some of the watchmakers in Switzerland in 1825. In the following year a Swiss engineer, Oppikofer, brought out practically the same design.

According to an estimate made by Bauernfeind, of Munich, at this period a billion areas had to be estimated annually in Europe, so that the practical importance of getting a reliable instrument was very great.

An instrument on Oppikofer's design was made in France by Ernst, and was there known as Ernst's planimeter. In England, about this time, Sang's planimeter was made. In Germany improved instruments of the same type were known as Wetli-

* A Paper read before joint meeting of Sections A and G, British Association.

Digitized by Google

Hansen planimeters. They are all practically of Gonnella's and Oppikofer's design, with very little difference.

In 1854 Amsler made his first planimeter, which created quite a revolution in this class of instruments. His first paper on the subject was published in 1856 and contains a great mass of information on various types of planimeters.

Classification of Planimeters.—Professor Hele-Shaw in his paper on "Mechanical Integrators"* bases the classification of planimeters on the mechanism used, and particularly on whether slipping or no slipping takes place. A better classification seems to me to rest on their geometrical properties.

Sir Frederick Bramwell, at the Brighton meeting of this Association, gave the first account in English of the theory of Amsler's planimeter, and then expressed his surprise and wonder at the fact that there could be any connection between the area of a closed curve and the motion of a tracing point

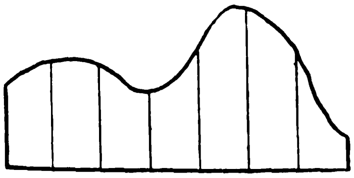

FIG. 1.

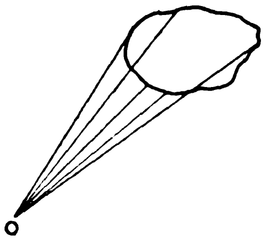

FIG. 2.

moving round its boundary. At first sight there is apparently no connection. But consider the given area as generated by the motion of a straight line. A line moving in its plane has two motions possible, translation and rotation; the line itself may either be of fixed or variable length. Adopting this as the basis of classification there are three types of planimeter:—

(1) In instruments of the first type, or orthogonal planimeters, the area is generated by the motion of a line of variable length which moves without turning (Fig 1); corresponding to a system of rectangular co-ordinates.

(2) In planimeters of the second type, the generating line is of variable length, and always passes through a fixed point (Fig. 2); corresponding to a system of polar co-ordinates.

(3) In the third type, the area is swept out by a line of fixed length.

Planimeters of the third type.—Let Q T (Fig. 3) be a rod of fixed length l; its motion into any neighbouring position Q′ T′ may be decomposed into a motion of translation into Q′ T″,

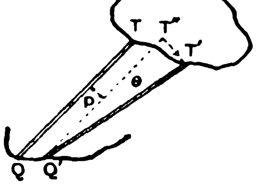

FIG. 3.

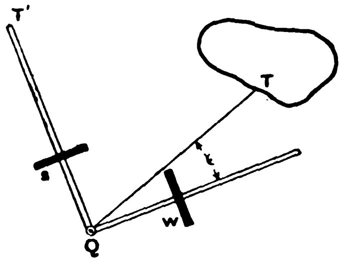

FIG. 4.

and a motion of rotation through the angle T″ Q′ T′ = θ. The area swept out by the rod is $lp + \frac{1}{2}l^2 \theta$, where p is the length of the perpendicular between the two neighbouring parallel positions of the rod. Now, if the rod ultimately return to its initial position, its ends Q and T will have described closed curves. There is a geometrical theorem, which I shall not attempt to prove here, that the area swept out by the rod in a complete cycle is the difference of the areas of the curves described by its ends. Now, if Q moves to and fro along a curve, the area described by it is zero, and the straight line sweeps out an area exactly equal to the area of the curve (T). Therefore area of given curve $= l \Sigma p + \frac{1}{2} l^2 \Sigma \theta$.

But by coming back to the initial position of the rod, $\Sigma \theta = 0$, and

$$\text{Area} = l \Sigma p.$$

* Proceedings of the Institution of Civil Engineers, Vol. 82.

Now suppose on the rod there is fixed a wheel which can turn with its axis parallel to the rod, as the rod moves the turning of the wheel will be equal to p; and if the total rolling of the wheel be w,

$$\text{Area} = l\,w.$$

This is the whole theory of the Amsler planimeter. In the Amsler planimeter the point Q is guided by the pole-arm in an arc of a circle.

I have dwelt at length on this part of the subject because of its importance with regard to the errors of the instrument. It does not matter where the wheel is fixed along the bar, or whether it be on a bar parallel to the original bar, provided its axis is parallel to the bar. In the Amsler instrument non-parallelism is one of the most important errors; the magnitude of the error can be determined as follows:—

Let the axis of the wheel (Fig. 4) make an angle ϵ with Q T; let Q T′ be equal to Q T and at right angles to the axis of the wheel; and let another wheel, whose total rolling is s, be fixed with its axis parallel to Q T′; then it is easily proved that the area

$$(T) = l \cos \epsilon,\ w + l \sin \epsilon,\ s.$$

Hence, unless s or ϵ is zero there will be an error, which is sometimes very serious.

Now the rolling s measures the slipping of the wheel w, due to the motion of translation of Q T′, and this slipping introduces a still more serious error. In 1855, Clerk-Maxwell pointed out slipping was a serious drawback, and he proposed, but did not carry out, an integrator without slipping.

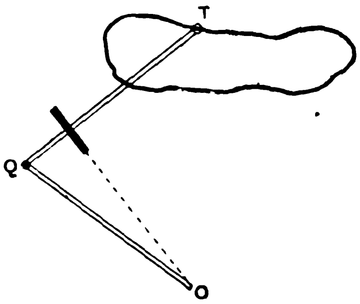

FIG. 5.

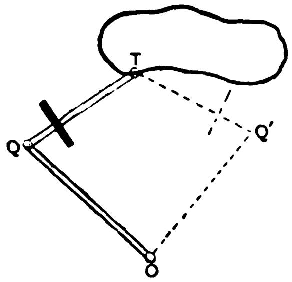

FIG. 6.

The Amsler instrument of 1856 has been improved, especially by Coradi of Zürich. In Coradi's "precision-planimeter" the wheel rolls on a prepared surface, with the object of avoiding the errors due to slipping. The errors due to slipping depend upon:—

(1) The resistance to the slipping of the wheel, and therefore on the nature of the surfaces of contact;

(2) The resistance of the wheel to turning, including the bearings resistance of the rolling wheel and the counter gear;

(3) The amount of slipping of the wheel on the paper.

The errors due to slipping will be reduced, therefore, by reducing these resistances. Again, if the plane of the wheel passes through o (Fig. 5), in moving T on a circular arc with centre o, the wheel will not roll at all, but slip. Hence, in using the instrument, the pole should be chosen so that such positions are avoided. Coradi has found that by varying the position of the pole the area registered varies, and has given rules for obtaining the best results. It should be remembered that the Amsler planimeter, by skilful use, is capable of very great accuracy.

Improvements by Coradi.—The Amsler instrument cannot be turned round; but, in a recent instrument by Coradi, the rod and the pole arm are connected by a spherical joint, so that it can be used with the joint first on one side, then on the other side (Fig. 6). The effect of this is to eliminate the error due to obliquity; in one position ϵ is positive, and in the other negative; thus the most important error in the Amsler planimeter is eliminated.

A number of new constructions have been made with the object of avoiding the slipping altogether. Clerk-Maxwell devised an instrument, which has never been carried out. Amsler, also, in his Paper of 1856, had foreshadowed a great

Digitized by Google

many schemes which have been afterwards re-designed by others. In his Paper of 1884 he designed an instrument with no slipping, but had not carried it out.

A planimeter to be successful commercially must be (1) easily handled, (2) accurate, (3) cheap.

Coradi's Spherical Planimeter.—In this the slipping is reduced to a very small amount, and for ordinary purposes the instrument is of greater accuracy than is really wanted. For engineering purposes the simple Amsler planimeter is accurate enough. For special purposes the spherical planimeter is very convenient.

Another Planimeter is that in which the distance moved normally by the rod is measured by the *slipping* of the wheel. A knife-edged wheel rolls on the paper, and can slip along a spindle at right angles to the arm (Fig. 7), thus taking the place of the Amsler recording wheel. Amsler described an instrument of this kind, in which, however, the knife-edged wheel was fixed to the spindle, which again slipped through the rod.*

This instrument has been made in America especially for measuring the areas of indicator diagrams. Now it follows from what I have said about the Amsler planimeter that the sliding rod must be at right angles to the arm. In the Hine-Robertson planimeter this is not the case, and I can conceive no reason for the construction actually used. (Fig. 8.) The rod is bent, and the sliding bar is at right angles to the straight portion of the rod, instead of being, as it should be, at right angles to the straight line Q T. Prof. Perry tells me that in the hands of his students it gave an accuracy greater than the ordinary Amsler planimeter. That the instrument gives good results is due to the fact that the areas measured are small,

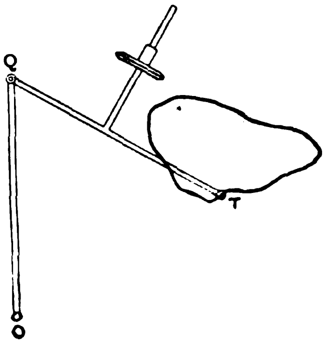

Fig. 7.

and that if the indicator diagram be low down the error due to obliquity is very small. In fact, one can get one position for a given area in which the error is zero.

Integrators are not used so much by engineers as they might be. Amsler's moment-planimeter gives—for one tracing round a given curve—the area, the first moment about a given straight line, and a third reading, by means of which with a little arithmetic the position of the mass centre and the moment of inertia about an axis through the mass centre are obtained. These are just the three quantities an engineer wants in determining the strength of a beam. Shipbuilders use it a little more, but not so extensively as it deserves. Amsler has made a few hundred moment-planimeters, while he himself had made over 12,000 planimeters up to 1884.

To return to instruments of Type 1, this planimeter gives always the area from the starting point to any point one likes. If a recording pencil could be attached to the instrument it would be an *integraph*, which draws the integral $\int y\,dx$, y as a function of x being given not as an expression, but as a curve drawn on the paper.

The integraph of Abdank-Abakanowicz was one of the first conceived, and is similar to that of Mr. Vernon Boys, a model of which is exhibited. The history of this instrument is rather interesting. Mr. Boys, one evening, had been reading a book on the Integral Calculus, went to bed, but instead of going to sleep invented the instrument; the next day he began to make it, and on the third day he finished it. A knife-edged wheel rolls on the paper, and is guided so that the tangent of the angle its plane make with the axis ox (Fig. 9) is equal to the corresponding ordinate y of the given curve. The ordinate Y of the curve, described by the knife-edged wheel, is then such that $\frac{dY}{dx} = \tan\phi = y$, and therefore $Y = \int y\,dx$, or the curve described by the knife-edged wheel, is such that its differential co-efficient is equal to the ordinate y of the given curve. To make the wheel actually draw the curve on the paper, a piece of thin blackened paper is placed blackened side downwards between the wheel and the drawing paper: a very clearly defined curve is the result.

Abdank-Abakanowicz introduced the same principle in his design, which he submitted to Coradi, and the instrument exhibited is the result. If one is given a function—not by an expression, but by a curve—the instrument will give the integral of the function as a curve; so that, for engineers, I think integraphs have a great future.

I think the first conception of an integraph is due to Lord Kelvin; but in the instrument suggested by him the integral is recorded on a cylinder and not on a drawing board, which is more convenient. He also mentioned that it would be possible to design instruments to give integrals of certain differential equations. His brother's cylinder-ball-and-disc integrator forms the basis of this design.

Sharp's integrator is not based on the *tangent* principle, but on what might be called the *sine* principle. It is curious to consider how the mechanism of this integrator reduces to somewhat the same thing as in *tangent* integraphs, but the geometry is essentially different. I have had this model made, it was only finished a few days ago, so that practical tests have not been made. It is essentially an integraph; but by the addition of the third carriage, as in the model, one can integrate the differential equation

$$\frac{dy}{dx} + ay + f(x) = o$$

a being a constant and $f(x)$ being given by a curve. If I move the tracer over the given curve $f(x)$, the pencil draws the

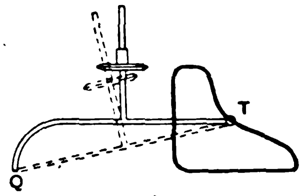

Fig. 8.

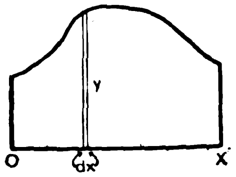

Fig. 9.

integral of the differential equation. If one wants to integrate differential equations of higher order, additional integrators must be added to the instrument. Any linear differential equation of the second order might be integrated by Sharp's instrument; the mechanism would not be too complex.

A great many observations are obtained by physicists and recorded as curves. It seems to me that to be able to work with these curves, as with expressions, is very desirable. I have no time to enter into this now; to see what means there are in existence for dealing with curves the results of observations, and to see whether these means cannot be generalised.

It would be desirable to have differentiographs, but the mechanical differentiation of a given curve seems so far impossible. The only way I think possible is to have the given curve engraved on a plate of metal, so that the tracer follows the curve accurately. It is quite impossible to get a satisfactory differentiator in which the tracing point is guided by hand.

Harmonic Analysers will give the equation to a curve if the curve itself is given. Amsler, in 1856, gave designs for a harmonic analyser; but the first carried out was by Lord Kelvin for the analysis of tides. One of his design is at the Meteorological Office, and has been used for years. This is quite a large, heavy instrument, and cannot be moved about.

Some years ago I thought, in following Clifford's remarks on Fourier's theorem, that a simple harmonic analyser could be got, and devised the instrument here shown, in which an Amsler planimeter rests with its pole and recording wheel on a plane surface subjected to a simple harmonic motion in its own plane, while the tracer moves along a fixed straight line.

* See *The Electrician*, Vol. XXVI., p. 432.

Digitized by Google

I then, by transforming the integral, designed another instrument, which gave two coefficients for one tracing of the curve. I then adopted an inversion by Mr. Sharp, and got another instrument made by Coradi. Last year he proposed the addition of a sphere, and the mechanism comes very near that of Professor Hele-Shaw. This instrument works so very easily that I cannot express my admiration sufficiently for the skill which the instrument maker has put into it. That the instrument is so perfect is altogether the work of Coradi. It will give the first five terms of Fourier's series, *i.e.*, ten integrals for going once round the curve.

Applications.—Obvious applications are to the analysis of meteorological observations, and to the analysis of dynamo curves of varying strength, &c. Professor Perry, for instance, tells me that his knowledge of valve gears of steam engines has been greatly increased by submitting their motions to harmonic analysis.

APPENDIX.

Harmonic Analyser.—Fig. 10 is an illustration of an harmonic analyser with one integrator by Coradi of Zurich. This has already been described by Prof. Henrici in "On a new

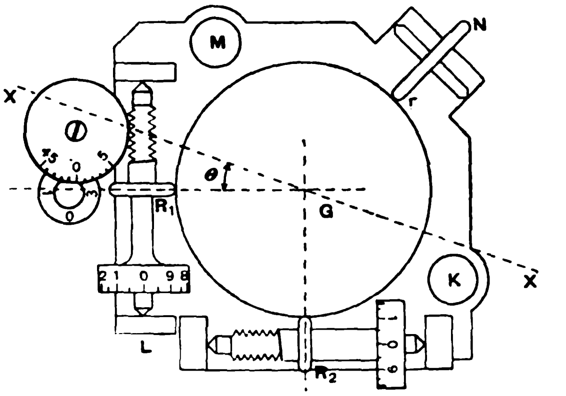

FIG. 11.

Harmonic Analyser," *Philosophical Magazine*, July, 1894. The long rectangular frame of the instrument rests with three wheels on the drawing-board. One of these, D, in the middle of the front serves merely as a support. The other two, E E, are fixed to the ends of a long axle which runs along the back of the frame. This may be called the "shaft." It is placed parallel to the axis of x. The instrument can therefore roll over the paper in the direction of the ordinates y. If thus can be moved through a distance equal to the base c to which the curve is drawn. To the carriage a silver wire is attached, which is stretched along the front of the frame, and then, by aid of the guide pulleys l l over the pulley H on the top of the spindle S. By giving the pulley H a suitable diameter the spindle can be made to turn n times round, whilst the tracer describes the whole base. If the tracer on following the curve has reached a point P then the spindle will have turned through an angle $n\,\theta$, where θ corresponds to the x of P.

The spindle has firmly attached to its lower end a square frame K L M N (Fig. 11) by aid of two solid rods K and M. This frame holds two registering wheels R^1 and R^2, with axes K L and L M at right angles. Between these lies the glass sphere G, resting with its lowest point on the cylinder belonging to the shaft. A third wheel r at N is, by aid of a spring, pressed against the sphere to secure contact between the latter and the registering wheels. If now the tracer follows the curve the frame will turn with the spindle, and the three wheels will carry the sphere with it, which will turn pivot-like on its lowest point. If, as in Fig. 11, the plane of one wheel R^1 makes with the axis of x an angle $n\,\theta$, and if in this position the tracer, and with it the whole instrument, is moved through the distance $d\,y$, the shaft will turn proportionally to $d\,y$, as will also the sphere about its horizontal diameter $x\,x$ parallel to the shaft. The turning communicated to R^1 will be proportional to $\sin n\,\theta,\ d\,y$, and that communicated to R^2 will be proportional to $\cos n\,\theta,\ d\,y$. If the tracer moves round the whole curve, these two wheels will therefore register numbers proportional to A_n and B_n. The dimensions are so chosen that the readings give $n\,A_n$ and $n\,B_n$ in centimetres.

Fig. 12 illustrates an analyser with five spindles, giving the first five pairs of coefficients A, B, in Fourier's expansion, for *one* tracing of the curve. The integrators are the same as in Fig. 10. The pulleys at the top of the vertical spindles have their diameters in the ratio $1;\ \frac{1}{2};\ \frac{1}{3};\ \frac{1}{4};\ \frac{1}{5}$; so that the angular velocities of the spindles are in the ratio $1;\ 2;\ 3;\ 4;\ 5$. When the instrument is not in use each of the glass spheres is held firmly between two celluloid rings, placed one above and one below it. The same screw which is used to press the wheel r against the glass sphere serves to release the sphere from the celluloid rings.

Sharp's Integraph.—The mechanism of the integrator has been described in a Paper read at the Physical Society, June 22, 1894. Fig. 13 is a diagrammatic plan of the instrument exhibited. The frame, rectangular in plan, rests by three wheels w, w, and w, on the paper; two of these wheels are fixed on the same shaft, which is set parallel to the direction

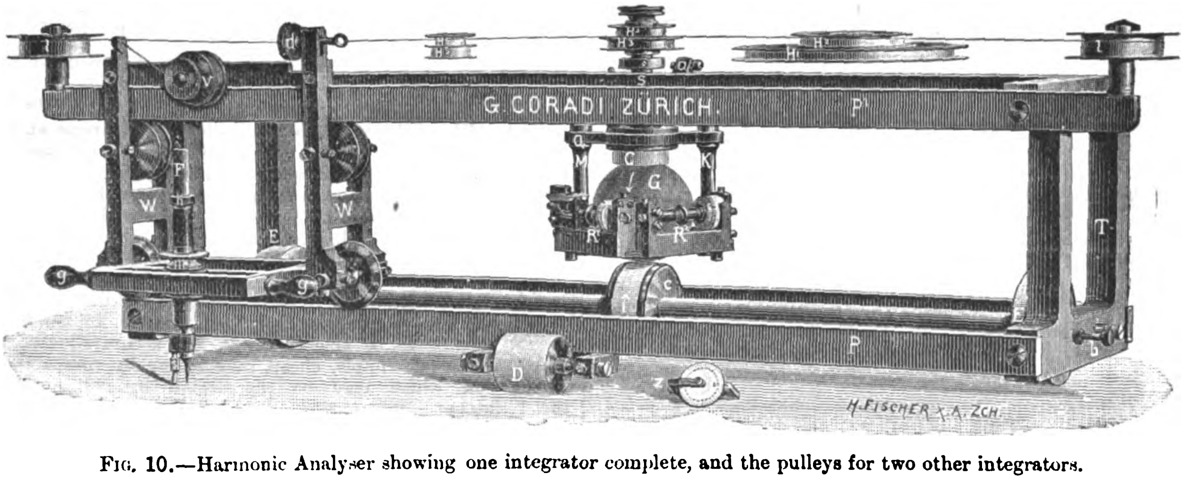

FIG. 10.—Harmonic Analyser showing one integrator complete, and the pulleys for two other integrators.

moved through a distance, $d\,y$, the shaft will turn through an angle proportional to $d\,y$. The shaft carries a short "cylinder," C, above which is a vertical "spindle," S, whose geometrical axis cuts that of the shaft. A pulley, H_3 or H_4, is fixed near the top, and the integrating apparatus proper near the lower end of the vertical spindle.

The spindle is turned as follows: Along the front of the frame runs a carriage, W, to which the tracer F is fixed. This of the ordinates y. On this shaft is formed a spherical enlargement b, on the top of which rests the horizontal cylinder c. This cylinder is pivoted on a frame carrying also the pulley p_2 with vertical axis; the frame can run on rollers on another frame which forms one rigid piece with the lever l, and which can turn about the axis of the vertical spindle s. The vertical spindle s is carried by a bridge, B B, underneath which the integrating cylinder c and its frame can swing freely. A carriage

Digitized by Google

carrying the tracer T_1 can run freely along the rail R_1, parallel to the axis of y. A pin t at the end of the lever l engages in a slotted groove of the tracer carriage parallel to the axis of x.

Let the axis of x pass through the axis of the vertical spindle s, let ϕ be the angle the axis of the cylinder makes with the axis of y, and let c be the length of the lever l, then

$$\sin \phi = \frac{y}{c}.$$

If, while the lever is in this position, the tracer T_1, and with it the whole instrument, be displaced a distance dx, the turning

cessively round the pulleys $p_1, p_2, p_3, p_5, p_6, p_7$ and then fastened to the tracer carriage T_2. If the tracer T_2 move over a given curve $f(x)$, then evidently the pencil P will draw a curve which is a particular integral of the differential equation

$$\frac{dy}{dx} + cy + f(x) = 0,$$

c being a constant.

In order to avoid the use of springs or weights for keeping the wires taut, the wires and guide pulleys are duplicated as shown.

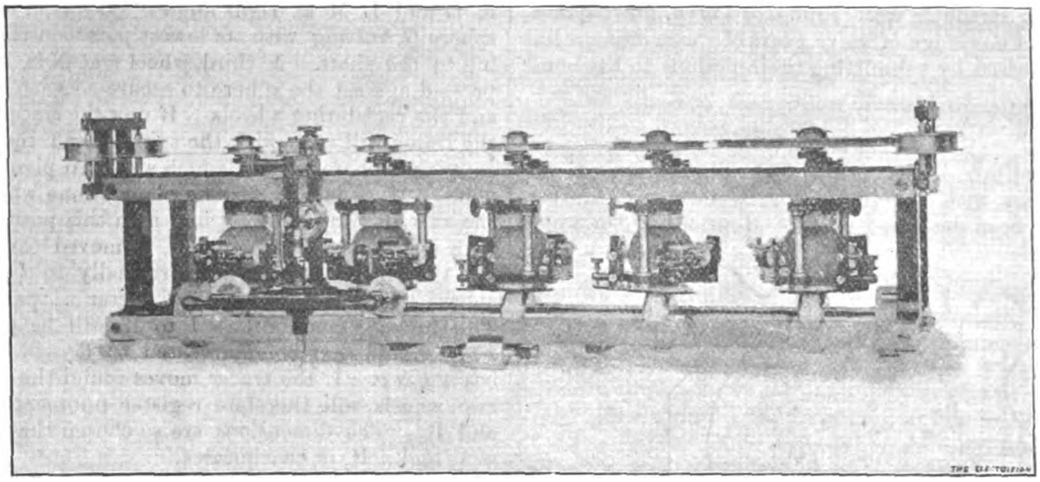

Fig. 12.—Harmonic Analyser with five integrators.

of the sphere b will be proportional to dx, and if there is no slipping between the sphere b and cylinder c, the turning of the cylinder about its axis will be proportional to $\cos \phi \, dx$, and the travel of the cylinder along its own axis will be proportional to $\sin \phi \, dx$, *i.e.* to

$$y \, dx$$

That is, the displacement of the cylinder carriage, and with it the pulley p_2, along its axis is proportional to the area of the given curve.

This displacement is transmitted to the carriage carrying the pencil P as follows: A pulley p_1 co-axial with the vertical

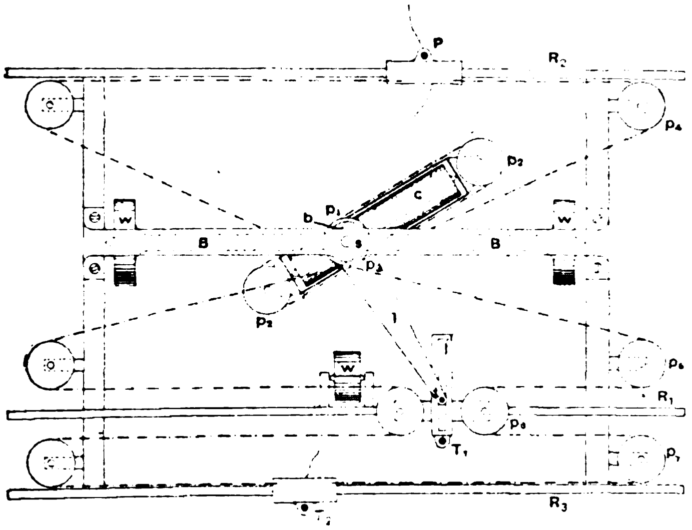

Fig. 1

spindle s, is *fixed* to the bridge B, a silver wire is wound round p_1, round the loose pulley p_2, round a *loose* pulley, p_3, co-axial with s, then round a guide pulley p_4, and fastened to the pencil carriage, which is free to move along the rail R_2 parallel to the axis of y. Thus, if no motion be given to the instrument in the x direction, a motion of the tracer T_1 in the y direction will produce no motion of the pencil P.

A third carriage carrying a tracer, T_2, moving along the rail R_3 is added to the instrument. A second wire is wound suc-

DISCUSSION.

Prof. EVERETT said that the first account of Amsler's planimeter of which he knew was given in Rankin's "Applied Mechanics." The treatise on "Mensuration" in Weale's series, published 1864, contained three different proofs of the property of the instrument. One of these proofs was due to J. R. Hyde, and consists in reducing it to particular case of Guldin's theorem: The length of a line multiplied by the normal distance moved through by its middle point is equal to the area swept out by the line. He had taught his classes for some years previous a similar proof, considering the bar to revolve about the point where the wheel is. A rigorous proof is obtained as follows: If any polygon moves in its own plane, the change in the area of the polygon is equal to the sum of the areas described by its sides. In the present case the polygon reduces to a triangle, of which two sides are of fixed length, and the length of the third side is variable. The change of area of the triangle—after the tracing point has moved once round the given curve—is zero, and therefore the area swept out by the three sides in zero. The area swept out by the pole-arm is, of course, zero; and therefore, with proper attention to sign, the area swept out by the bar is equal to that swept out by the third (variable) side of the triangle. But the area swept out by the variable side is $\frac{1}{2}\int r^2 d\theta$, the area of the given curve; which is therefore equal to that swept out by the bar, and registered by the wheel.

Prof. HELE-SHAW: It is impossible in the time at our disposal to properly discuss the Paper. The classification of planimeters which Prof. Henrici has adopted, and which admirably explains their action, is a geometrical one; the classification given by myself is a mechanical one. It is, perhaps, only natural that a mathematician should give a geometrical and an engineer a mechanical classification. I should like to discuss at length—but cannot on account of time limits—the question of classification. What we are interested in is the obtaining of a practical working instrument. There seems to be two distinct and different kinds of instrument; the one, expensive, complicated, difficult to use and requiring a special training to be able to use it, but accurate; the other, a workshop instrument, simple, cheap, easy to use by comparatively unskilled hands, and which may be represented by its latest development, the "Hatchet" planimeter. I think it would be desirable to have on some other occasion a discussion on this instrument.

Prof. C. V. BOYS: The only point to which I would like to refer is the question of making differentiators, and on this point, unless I have misunderstood him, I venture to differ from Prof. Henrici. The process of integration smooths off angles and irregularities, and if the given curve is irregular in outline the integral curve will be smoother and more regular. The process of differentiation, on the other hand, magnifies any irregularity in the given curve. I agree with Prof. Henrici that it is impossible to make a differentiator moved by a tracing point guided over a given curve. But take the case of my own integraph, consider the rolling wheel which draws the integral curve; it may be viewed as the front wheel of a bicycle. If the rider of the bicycle can so control his steering that the front wheel follows exactly a curve drawn on the ground, the case would be analogous to the conversion of the integraph into a differentiator. Let the given curve, the differential of which is required, be drawn on the paper, and let

Digitized by Google

the instrument be guided by moving the tracing point up and down in the y direction as the instrument moves in the x direction, so that the rolling wheel moves over the given curve; the tracing point will then describe a curve which is evidently the differential of the given curve, since the given curve is the integral of the curve described by the tracer.

THE DIFFUSION OF LIGHT BY DULL SURFACES.*

BY CHRISTIAN WIENER.

Historical Data, and Nature of Dispersion.

The investigations concerning the dispersion of light by dull surfaces described and discussed in the following Paper, were suggested to me by the problem, appertaining to my teaching subject of descriptive geometry, of representing bodies with their appropriate degrees of brightness. The richest sources of theoretical and experimental investigations capable of affording a basis for the solution of this problem are even now found in two works dating from the middle of last century, viz., Lambert's *Photometria* (Augsburg, 1760), and Bouguer's works on optics (Paris, 1729 and 1760). These works have, up to the present, hardly been utilised for that purpose, and I have, in my treatise on descriptive geometry, attempted to draw upon them to a greater extent. Now, whereas the intensity of illumination of an element of the illuminated surface is known to be proportional to the intensity of the source divided by the square of the distance from the element and multiplied by the cosine of the angle of incidence ϵ, the brightness of the element as it appears to the eye is proportional to that intensity of illumination and to the reflective capacity (Lambert's *albedo*). But the direction along which the element is seen may also have some influence. This influence is determined, according to Lambert, by the cosine or *Lambert's law*, according to which a surface element which diffuses the light received, reflects under an angle of reflection a an amount of light which is proportional to cos a. But since the apparent size of the element is also proportional to cos a, the brightness of a dull surface is, according to Lambert's law, independent of a, or the surface appears with the same brightness from whatever point it may be observed.

But that Lambert's law is not generally true was already shown by Bouguer's observations. He found, in a manner also adopted in my own experiments, that when the direction of incidence and of vision were nearly parallel, the brightness was not proportional to cos ϵ, as it should have been according to Lambert; but that with increasing ϵ it decreased more rapidly than cos ϵ.

In drawings, Lambert's law, although not strictly correct, is employed almost exclusively, and with good effect, the brightness being taken as proportional to cos ϵ. On the other hand, it has been proposed to make the brightness equal to cos ϵ . cos a, and again to cos ϵ : cos a. The substitution of cos ϵ . cos a is, however, certainly incorrect. For that would make the brightness zero for $a = 90^\circ$, or for places where the lines of vision touch the surface, *i.e.*, at the boundary. This is in direct opposition to common observation. The substitution of cos ϵ : cos a was proposed by Brisson (in his edition of Monge's *Géometrie Descriptive*, 1827). According to that law the boundary should appear brightest, and Brisson really refers to the circumstance of the full moon's limb appearing brightest, although containing the terminator between light and darkness, and therefore the least illumination. But Bouguer and Zöllner explain this phenomenon by the obvious consideration of the strong inequalities of the moon's surface, and as a matter of fact a body with a smooth but matt surface does not show a brighter contour (as will also be shown later on), especially if the contour is also the boundary between light and shade.

Herr Lommel† has also made some theoretical investigations into the diffusion of light by starting with Fourier from the supposition that this diffusion does not proceed from the surface, but from volume elements of the mass of the body, as is demanded by the colouring of the diffused light. For opaque, solid-glowing bodies he thus arrives at the cosine law; for the length of the path described in the interior of a body by a ray of light before its complete absorption depends only upon the absorptive power, but not upon the angle of emergence a, so that the vertical depth of this diffusing layer, and hence also the amount of the diffused light must be proportional to cos a. This result was confirmed by Herr Möller‡ by observations of glowing metal plates. In a later Paper§ Herr Lommel investigated the brightness of diffusing bodies, and followed up the gradual absorption of the light penetrating to a certain depth and its emergence. He thus arrived at a formula for the intensity of the reflected light, which depends, after the absorptive and diffusive power of the substance and the thickness of the diffusing layer—the latter only of importance when very thin—only upon the angles of incidence and emergence ϵ and a, and is symmetrical with respect to these, so that the quantity of the light reflected by an element of the surface is not altered by exchanging the incident and emergent rays.

These results are based upon the tacit assumption that no reflection takes place, and that the surface is perfectly matt or rough. And for such surfaces they are perfectly cofirmed by Angström's extensive observations on the diffusion of radiant heat carried out at Strasburg.* By smoking with various substances, or by decantation from liquid suspension he produced perfectly matt or rough surfaces, which showed no reflection even at high angles of incidence, and found the above laws confirmed within a fair approximation. But other bodies, such as paper and cast gypsum showed increased brightness in the direction of reflection. . . .

The explanation of the diffusion of light by dull surfaces has been based upon two assumptions. The first is that of the penetration of the disturbance to a certain depth, and the radiation in all directions of this disturbance out of the layer penetrated. This view is supported by the colour possessed by the dull surfaces, and by many experiments, such as those of Angström, according to which the diffusion increases, within certain limits, with the thickness of the dull layer laid upon a previously smoked surface; thus, in the case of magnesia 0·26mm. thick it was, *ceteris paribus*, about double what it was with a thickness of 0·05mm.

It was upon a different hypothesis that Bouguer based a detailed theory of the diffusion of light. He supposed the rough surface to consist of a large number of small plane-reflecting surface elements lying in all directions. The total area of these surfaces in a given direction is greatest in the direction of the general surface, and decreases as the angle to it increases, thus producing a preponderating reflection in the sense of the effect of the general surface. To determine the amount of the surface elements in a given direction, Bouguer measured for different bodies the brightness observed when the directions of incidence and emergence very nearly coincided. Since in this case, according to his assumption, it is only the surface elements perpendicular to this direction which have any effect, and these are always at the same zero angle of incidence and emergence, the total area of the surface elements thus arranged is proportional to the brightness produced. . . . In making the amount of reflected light only dependent upon the direction of the bisector of the angle between the incident and the emergent ray, but not upon the magnitude of this angle, he neglected the fact that with a large angle of incidence the reflection is much stronger than when it is small, although on another occasion he proves it experimentally in the case of pure mirrors. His limited experiments with dull surfaces did not bring him face to face with the contradictions of his theory by the facts, as he only observed with the incident and emergent rays coinciding.

We therefore arrive at the result that in the case of dull surfaces we have to deal both with a penetration of the rays and with a diffusive reflection by small surface elements. But these circumstances are so different with different degrees of roughness and with the different forms of the prominences that in each case nothing but observation will give a clue to the actual state of things.

Let me therefore now describe the observations made in 1883 with the assistance of my son Otto in the case of cast gypsum, as well as the surfaces of brightness resulting from these observations.

The Diffusion of Light by Cast Gypsum.

I procured two equal square plates of 25cm. side, made of the best white gypsum, and illuminated them in an otherwise dark room by one stearine candle (six to the pound) each. I could enlarge their flames by bending the wicks into the interior of the flame, and kept the flames as much as possible of equal size. As a unit of brightness I adopted that shown by such a plate when illuminated perpendicularly by a candle at a distance of 1 metre, and seen perpendicularly. The directions of illumination and vision could not really coincide, but since the brightness does not change much with small deviations from the angles of incidence and emergence, both angles could be taken as equal, and equal to zero. The distance of the observer's eye from the plate has no influence upon the brightness. The light was shaded from the eye by a screen. When the distance of the light from the first plate (which we shall denote by I.) was altered from 1m. to am., with $\epsilon = a = 0^\circ$, the brightness changed in the proportion 1 : a^2, and this served as a measure of brightness for the second plate (II.). The latter was placed so that its margin and that of I. apparently coincided, and that it was observed by the eye under the angle of emergence a. It was then illuminated by a second candle at a distance of bm. at an angle of incidence ϵ in such a manner that the azimuth (the angle between the plane of incidence and that of emergence) was ν. The two sources of light were screened in such a manner that each of them only illuminated one of the plates, and that neither

shone into the eye. Then plate I. was shifted until both plates appeared equally bright at their apparently coincident edges, so that their images coalesced, and observation was aided by holding in front of the eye a screen with a hole through which one could only see small and apparently nearly equal portions of the two plates. Then on measuring the distance of Plate I. from the light, and finding it $=a$, the brightness of the two plates was $1:a^2$, and the brightness H of Plate II. would, with the light at 1m., be $H=b^2:a^2$. But this is the quantity required, viz., the brightness exhibited by Plate II., at an angle of incidence ϵ, an angle of emergence a, and an azimuth ν, when illuminated by a light at a distance 1m.

To measure these last three angles, or rather to produce certain magnitudes of them, I cut a circular disc of cardboard of about 18 cm. radius, cut it through along one radius, and made a light cut along the radius produced, and along another radius at right angles to it, so that by bending a solid angle could be produced (Fig. 1), with two right-angled sides and angles, but so that the third side and angle could be changed together from 0° to 180°. On placing this variable side upon the plate of gypsum, the edge not lying on it represented the normal to the surface, the rectangular sides bounded by it were used as planes of incidence and emergence, and the third or variable side gave its azimuth. The azimuth angles being divided from 30° to 30°, the angles of incidence and emergence from 15° to 15°, and also indicating 82½° and 86¼°, and a string attached to the vertex being directed in those planes towards the eye and towards the light, it gave the angle of incidence and emergence, while the basal semicircle showed the azimuth. The movable right angle was sometimes fixed on a certain azimuth by paper strips stuck on, so that all measurements could be taken for that azimuth in succession.

In this manner the brightnesses were measured for the values of ν, a, and ϵ referred to, two or more readings—in rare cases only one reading—being taken for the same angles. Thus, for $\nu=30°$, $\epsilon=30°$, and $a=75°$, the distance of Plate II. from the light was $b=1·225$m.; then Plate I. was shifted under perpendicular incidence and emergence until it appeared to fuse with II., and its distance from the light was then found to be $a=1·465$m. At a

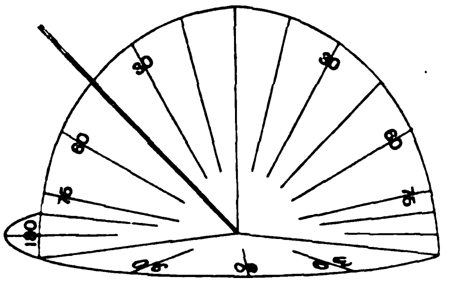

Fig. 1.

distance of 1m. the brightness of II. would then have been $H=(1·225:1·465)^2=0·701$. A second reading gave $a=1·225$m., $b=1·405$m., whence $H=0·762$.

To obtain a measure of the accuracy attained, I placed the two plates of gypsum side by side, and exposed them at their edges to vertical illumination by the same source. Then I had one of them shifted until the images appeared to fuse, measured the distances of the movable one, and found them to vary between the extreme limits 0·746 and 0·774m., and therefore their brightness between $(1:0·746)^2$ and $(1:0·774)^2$; *i.e.*, between 1·797 and 1·666, or by 0·131. The greatest relative variation was, therefore, $0·131:1·738=0·075$, where 1·738 was the mean brightness. But the greatest departure from the mean was 0·072, and the relative departure $=0·072:1·738=0·0406$. The mean relative error was, therefore, $=0·0196$. The uncertainty was greater when two lights were employed, whose difference was then brought into play. The differences between two measurements could then amount to 0·1 of the brightness; in rare cases to 0·15. On the average the relative departures of two measurements from each other was 0·06, hence the departure from the mean 0·03. If, on the other hand, differences of brightness of 0·01 and less could be observed—as in the case of a feeble grey ring on a white background, produced on a rapidly rotating white disc by a black streak—it must be borne in mind that in this case only one source of light was brought into play, and that the eye is peculiarly sensitive to such a ring surrounded by white spaces.

Considering the error attached to the measurements, their comparison had to be undertaken with all the greater care. This was done geometrically according to the law of continuity. Surfaces of brightness could be drawn, after Bouguer's example, in various ways. If, for a certain incident ray—that is, for a certain value of ϵ—the brightness H is cut off along each ray proceeding from the same point, F, of the surface, the terminals of these lines representing the apparent brightness of the surface form a surface called the surface of brightness. By Lambert's law this brightness would be uniform and $=\cos\epsilon$, and therefore the surface of brightness a hemisphere of this radius. But if along these rays are cut off the quantities of light radiated from the same surface element, taken as the unit of surface, these quantities being $=H\cos a$, we should obtain another surface, that of radiated quantities of light, and this would by Lambert's law be another sphere, but touching the surface in F, and of a diameter equal to the radius of the first hemisphere. Finally, we may draw from F a fixed emergent ray, with constant a, and cut off along each ray incident upon F of the same intensity, the brightness imparted to the surface under its influence. This might be called the *surface of illumination*, since for every direction of illumination it gives the brightness along a fixed line of vision. It differs from the surface of brightness by touching the illuminated surface in F, whilst the surface of brightness cuts it along an extensive curve, because for glancing rays of light the brightness becomes zero, but remains finite for glancing visual rays. By Lambert's law we should have to cut off the brightness $\cos\epsilon$ along each incident ray, hence the surface would be a touching sphere of unit diameter; it would be independent of a, and, therefore, the same for every direction of the emergent ray. In the following we shall only consider the brightnesses, but not the quantities of light radiated by unit surfaces, so that we shall only have to deal with the surfaces of brightness and of illumination.

Now, these surfaces are continuous, and by means of their continuity we may correct the errors of the measurements. In the surfaces of brightness ϵ is invariable; and on laying a plane through the normal to the surface we obtain a curve of intersection for whose two halves we have the azimuths ν and $180°-\nu$ with constant ν, in which H only varies with a. We shall call such a curve a *meridian curve*. But if we describe an intersecting cone with F for its apex and the surface normal for its axis of revolution, *i.e.*, with constant a, H will vary with ν. Such a curve we shall call the *cone curve*. In the same manner the surface of illumination gives meridian curves and cone curves.

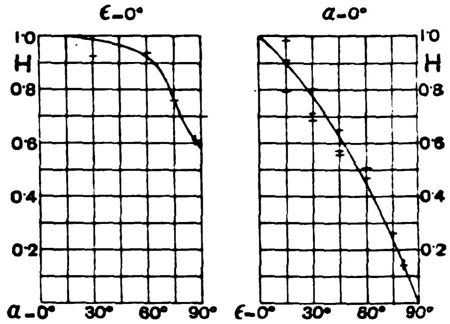

Fig. 2.

Since H depends upon the three independent variables ϵ, a, and ν, we obtain these curves by leaving two of the latter quantities constant; then H is only dependent upon the last of the three variables. Since ϵ, a, and ν are angles, and H a ray, each of the curves is given by polar co-ordinates. Cutting off on these rays the values of H obtained by measurement, the curve drawn through their terminal points will not be continuous on account of the errors of measurement, and we must then draw a continuous curve as far possible approximating to the points derived from observation. Thus we attain three species of curves:

(1) With constant ϵ and ν, the meridian curve a H.
(2) With constant a and ν, the meridian curve ϵ H.
(3) With constant ϵ and a, the cone curve ν H.

The last curve lies on a cone of revolution, and takes two forms, since in one case the constant ϵ denotes a fixed incident ray, and the curve lies on the cone $a\,\nu$, and in the other case a denotes a fixed emergent ray, and the curve lies on the cone $\epsilon\,\nu$. But the determining elements ν H are the same in both cases. Thus we obtain essentially only the three kinds of curves enumerated above. If one of these curves, *e.g.*, that for a H, belonging to a certain ϵ and ν, is kept continuously in the neighbourhood of the observed points, then we have a fixed system of four co-ordinate values of ϵ, a, ν and H for each ray of this curve. But the curves ϵ H and ν H contain the value of H for the same ray, and must yield the same value of H for it. Hence we are given the difficult problem of drawing three groups of curves, a H, ϵ H, and ν H which approximate to the points derived from observation, which are continuous, and in which the three values of H corresponding to the same a, ϵ, and ν are the same. The number of curves depends upon the intervals chosen. For measurement I usually chose intervals of 30°, for drawing usually 15°; in the measurements I chose for ϵ and a the angles 0, 30, 60, 75, 82½, 86¼, and 90°—the last angle being the limiting angle, obtained by con-

Digitized by Google

tinuous extrapolation—for ν the angles 0, 30, 60, 90, 120, 150, 180°. I drew 41 such curves by their polar co-ordinates, this producing true meridian curves, and the cone curves on the developments of the cones. But I found that the sensibility of the eye for continuity was not as great as could be desired, and I, therefore, proceeded to rectangular co-ordinates. A constant H gives with polar co-ordinates a circle, in rectangular ones a straight line. The deviations from a straight line can be more delicately perceived than those from a circle, and also in other curves deviations were more readily detected in rectangular than in polar co-ordinates.

To give an idea of the latter curves I have reproduced some of them. Fig. 2 gives the two most important ones, that for $\epsilon=0°$, *i.e.*, for the vertically incident ray, and for $\alpha=0°$, or the vertically emergent ray, for both of which ν is without influence. Fig. 3 gives the series of curves ϵ H for $\alpha=75°$, and for ν successively

2. As α further increases from 60° to 90°, the brightness on the whole diminishes, and at the limit of $\alpha=90°$, or with a glancing visual ray, it is about 0·6 times that at $\alpha=0°$.

3. On the side opposite to the incident ray—*i.e.*, on the side of reflection—the brightness is greater than at the corresponding points of equal α on the same side.

4. The reflection is more pronounced and evident the larger the angle of incidence ϵ. With $\epsilon=45°$, and even more with $\epsilon=60°$, it is shown by increased brightness, but not as yet by a clear reflected image or by superior brilliance. The greatest brightness H amounts for $\epsilon=60°$ to 1·03, whilst the mean brightness is somewhat smaller than cos ϵ or 0 5, and this applies to $\nu=180°$ and $\alpha=67°$, *i.e.*, in the case of an angle of emergence which is greater than the angle of incidence (60°). Even with an azimuth less than 180° a decided increase of luminosity is perceptible, up to $\nu=162°$. For $\epsilon=75°$

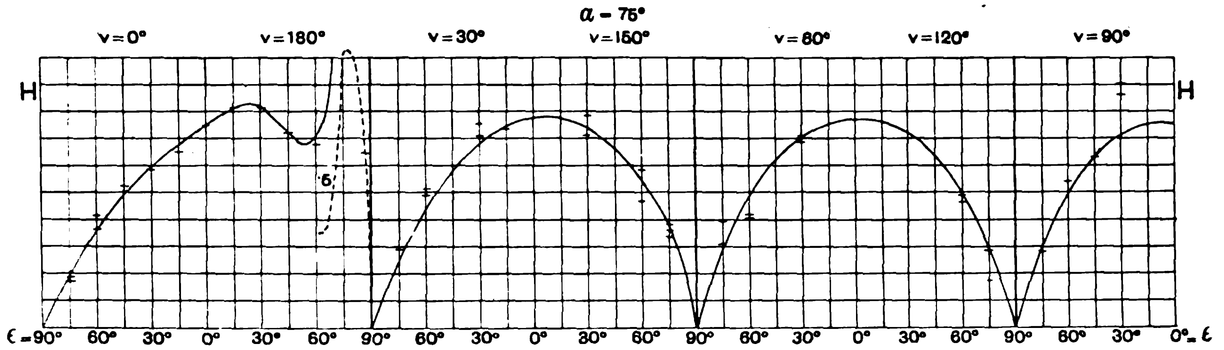

Fig. 3.

=0 and 180, 30 and 150, 60 and 120, and 90°. The ordinates H are filled in for the given values of ϵ, and the observed values of H are indicated by small dashes. Thus we obtain an idea of the degree of accuracy. Here we see that the observations for $\alpha=75°$, $\nu=90°$, $\epsilon=30°$ strongly diverge from the curve drawn, so that these observations are useless; perhaps in this case the sources of light had become very unequal. When $\nu=180°$ we observe the pronounced effect of reflection; the curve in this case could for some distance only be given in half ordinates. Twenty-three such series were drawn. These curves, like those for polar co-ordinates, had to be drawn so that they most closely approximated to the points of observation that they were continuous, and that each ordinate H, recurring in each of the three groups, had the same value at least three times. Thus the transition between neighbouring curves also became continuous. . . .

reflection and brilliance becomes evident, between $\alpha=73°$ and 90°, strongest with H=2·2 when $\alpha=79°$ and cos $\epsilon=0·26$. When $\epsilon=82\frac{1}{2}°$, reflection extends from $\alpha=73°$ to 90°, and is greatest with H=5·2 when $\alpha=85$ and cos $\epsilon=0·13$. For $\epsilon=86\frac{1}{4}°$, reflection extends from $\alpha=78\frac{1}{2}°$ to 90°, and is greatest with H=14·4 when $\alpha=88°$ and cos ϵ =0·07.

We notice, therefore, that reflection is always greatest with an angle of emergence α, always somewhat larger than ϵ. If we assume with Bouguer (confirmed by these results) that the area of the reflecting surface elements becomes larger as the angle between them and the general surface decreases, the phenomenon of α being larger than ϵ for strongest reflection is easily explained. For perceptible reflection α and ϵ are angles which exceed 60°, and do not differ much among themselves. If we now leave ϵ constant and make α exceed ϵ somewhat, then $\alpha-\epsilon$ and $\alpha+\epsilon$ will also increase as

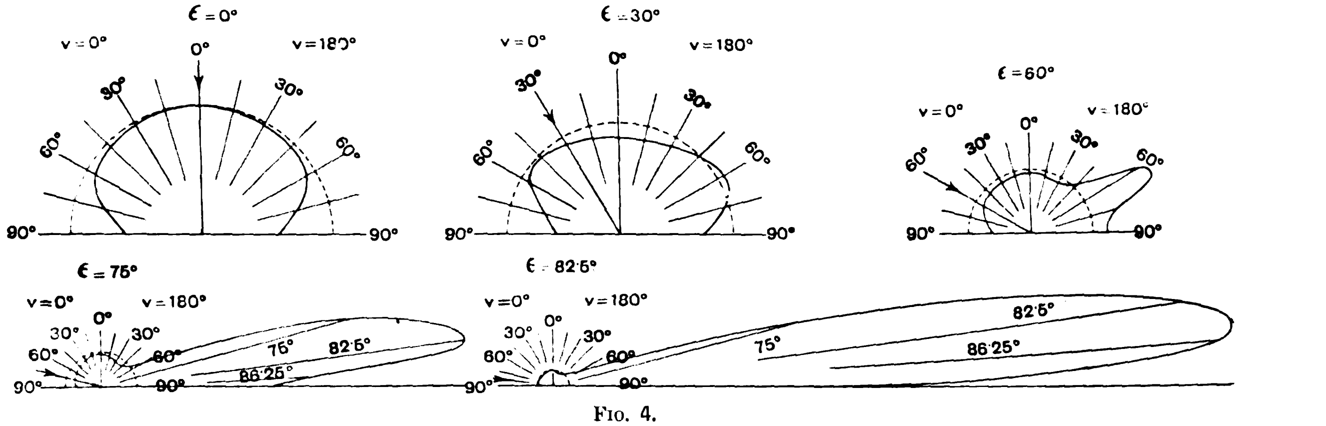

Fig. 4.

In Fig. 4 are given the meridians of incidence upon the surfaces of brightness, *i.e.*, for $\nu=0$ and $=180°$, and for $\epsilon=0$, 30, 60, 75, and $82\frac{1}{2}°$; the dotted semicircles are put in with radii cos ϵ, and therefore belong to the surfaces of brightness corresponding to Lambert's law, which are hemispheres.

In Fig. 5 are drawn the meridians of the planes of emergence for those surfaces for $\alpha=0$ and $=60°$; the dotted circles belong to the surfaces of illumination according to Lambert, which form equal whole spheres of unit radius independent of α. . . . .

From these results I have in the introduction drawn conclusions respecting the process of diffusion of light by cast gypsum and by dull but not rough surfaces in general. Concerning the observed strength of diffusion by cast gypsum we can draw the following conclusions from the tables, or from the diagrams and models :—

1. With a constant angle of incidence ϵ and an angle of emergence varying between 0° and 60°, the brightness is pretty uniform, and usually somewhat smaller than that demanded by Lambert's law.

α increases. But the angle between the reflecting surface elements and the general surface is $\frac{1}{2}(\alpha-\epsilon)$, and the total area of these surface elements decreases as α increases, but not much, since $\alpha-\epsilon$ always remains small. But $\frac{1}{2}(\alpha-\epsilon)$ is the angle of incidence and reflection for these surface elements, and as it increases the amount of reflection also increases, especially, of course, with higher angles of incidence as here supposed. This increase therefore exceeds the former decrease, so that the strongest reflection takes when $\alpha > \epsilon$.

As regards, therefore, the imitation of brightness in painting, we see that fairly true results are obtained by observing in general Lambert's law, by reducing the brightness to 0 6 times that obtained according to Lambert at high angles of emergence, especially with glancing visual rays; but, on the other hand, by employing higher lights as the point of reflection is approaching, which pass into shining spots as the angle of incidence ϵ increases

It is very desirable that further investigations should be undertaken with different bodies of different qualities of surface, and

Digitized by Google

with more delicate means than those at the disposal of the author, and that the surfaces of brightness should be determined in each case. For the art of painting such experiments would be of special

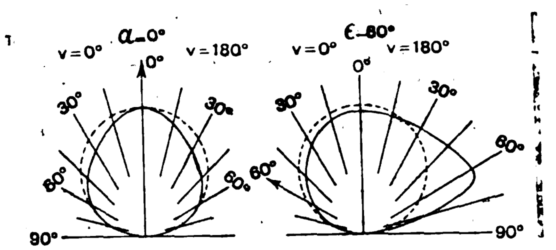

Fig. 5.

value in the case of dress materials, such as linen, cotton, silk, and velvet; and, further, the establishment of colour scales based upon these values.

THE ELECTRICAL EQUIPMENT OF THE LIVERPOOL OVERHEAD RAILWAY.

BY THOMAS PARKER, M. INST. C.E.

(*Continued from page 523.*)

When the Overhead Railway Company in 1891 decided to employ electric traction for their trains, the Electric Construction Corporation of Wolverhampton tendered for the equipment of the line, and secured an order for the complete installation, comprising boilers, engines, steam-pipes, dynamos, rolling-stock, station-lighting and signals. The plant was required to run a three-minutes' service on a double line 6 miles in length, and to accomplish this distance in twenty-nine minutes, including stops of half a minute at each one of thirteen stations. Each train was to consist of two cars, each car carrying fifty-six passengers, and being of an estimated weight of 12 tons 10 cwt. without motors.

To meet this service, twenty trains running at one time would be necessary, and in considering the power required at the dynamos, the subject was approached from its elementary basis. Curves were drawn to show the energy absorbed by one loaded train at every point in the whole length of the line, assuming various accelerations and intervals during which the brakes might be applied to bring the train to a standstill, the weight of a loaded train, with motors, being assumed to be 34 tons. These curves were modified and checked by the results of experience on ordinary railways, until results were obtained which would meet the service required. In most cases the stations were so near one another (in one instance under 300 yards, and in others 400 yards) that the brakes had to be applied long before the train could attain a uniform speed, the greater part of the energy supplied to the motors being expended in accelerating the motion of the train, which was required by the specification to attain a speed of 30 miles per hour, if necessary. From these curves it was an easy matter to calculate the power required for the whole service. This gave, allowing for the various electrical losses which were capable of being estimated, 1,200 to 1,400 amperes at 500 volts, which was the electrical pressure decided upon, or nearly 900 E.H.P. This was split into three units, and to allow for one spare, it was decided to use four dynamos for the generating plant, each having a normal output of 475 amperes at 500 volts, at 420 revolutions per minute, or, say, 1,200 E.H.P. in all.

Dynamos.—These are of the double limb type, with a magnetic circuit above and below the armature, the poles being cut through horizontally along the centre line to allow the upper part to be lifted readily. They are shunt-wound, of "drum" type, with stranded conductors. The resistance of the armature is 0·01 ohm, and that of the shunt is 75 ohms, the electrical efficiency of the machines being 97·7 per cent. The armature and shaft weigh 3 tons, and the complete machines 21½ tons each. Each dynamo is driven by nineteen 1¼-inch cotton ropes, from a horizontal compound engine, indicating 400 H.P. at full load.

The armature shaft carries a half-coupling, by which it is connected to the pulley shaft, which runs between two bearings; the armatures can thus be easily removed without disturbing the pulley and ropes. The dynamos are built on lines sufficiently massive to be capable of producing a much greater output than the normal for a short period without injury. They can check the engines, in the event of too heavy a call being made upon them, and so prevent any serious damage occurring to them in case of a continuous short circuit on the line.

Switchboard.—The switchboard was designed to ensure safety and simplicity in working. The current from each dynamo is connected to common omnibus bars through an ammeter and automatic magnetic cut-out, so that all can work in parallel. These cut-outs, which protect the generating plant, are also used as switches, and are thus always kept in working order. They are adjusted to break the circuit automatically when the current exceeds double its normal value, *i.e.*, 1,000 amperes, and have proved most effective. They came into frequent use whilst the trial runs were being made, before the contractors for the permanent way had finished their work on the overhead structure, when trolleys and materials lying about the line were continually causing short circuits. An iron bar could also be used in case of necessity at any part of the line as a main switch, to cut off the current by short-circuiting the conductor to the rails, without any other communication with the generating station, and it is probable that this was resorted to many times unnecessarily. A similar form of switch is used on the cars, and the guard can, independently of the driver, by applying the brakes, cut the current off the motors, and bring the train to a standstill.

From the omnibus bars the current passes through a main magnetic cut-out (adjusted to break circuit with a current of 3,000 to 4,000 amperes) to the centre conductor, from which the moving trains collect their current, by four $\frac{37}{13}$ "Callender" lead-sheathed and steel-armoured cables laid under the road between the generating station and the overhead structure.

Conductor.—The main conductor is of steel, 4 sq. in. in section (Fig. 1), rolled in lengths of 32ft. 6in., and weighs about 40lb. per lineal yard. It is supported between the main rails on wooden cross-sleepers, and rests on porcelain insulators. The insulators were designed for use with oil, but as the average leakage over the whole line is only 2 to 3 amperes this has been thought to be an unnecessary refinement. The steel channel is not rigidly

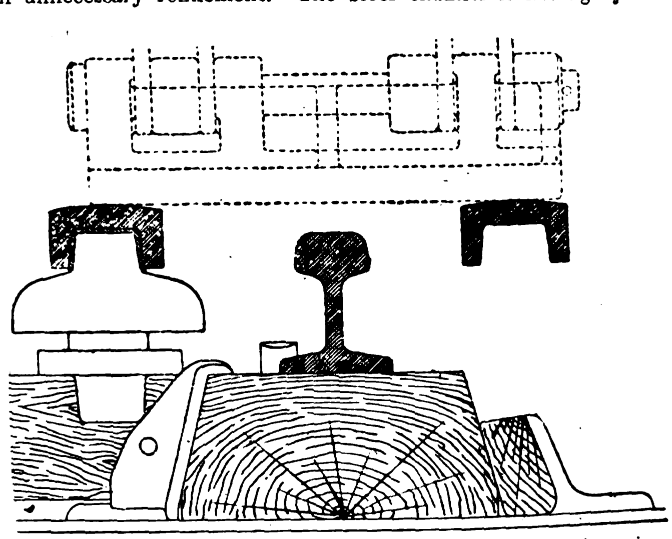

Fig. 1.—Section through main-conductors, rail, and sleepers at a crossing.

attached to the insulators in any way, and is supported by them at every 7ft. 6in., except where joints occur in the conductor, in which cases the insulators are 2ft. 6in. apart. The lengths of conductor are electrically connected by flexible copper straps. There are no feeders, and the return circuit is through the rails, which are united by wrought-iron bonds riveted to the web and bridging across the fish-plates. All four rails are cross-bonded at the stations, but are insulated from the structure by longitudinal sleepers. They weigh 56lb. per lineal yard. The return circuit has thus a sectional area of, approximately, 22 sq. in. At each station there is a cross-over road, and, in order to surmount the difficulty of carrying the charged conductor past the main rails at these points, it was broken, and each end was bent parallel to the main rail for some distance on each side of it (Fig. 2), being electrically connected under the rail, and fixed ⅜in. each above it. The collectors on the cars were made wide enough to bridge across the gap thus formed, without breaking the circuit.*

Cars.—The cars are of the "double-bogie" type, each car being an independent unit. To meet the conditions of the work, a motor was built with the armature direct upon the axle (of the type usually adopted by the author's firm for traction work) to give the torque effort required with ordinary "drum" winding four layers deep. Although this machine did all that was required of it in a test in the shops, the armature winding appeared so unsatisfactory mechanically that it was decided to experiment with a coil winding, and, after some practice, an armature was built with coils on Mr. Eickemeyer's system, described as a "winding composed of detachable counterpart coils, each of which is placed in immediate contact

* For illustration of these collectors, and for views of the line and engine room, see *The Electrician*, Vol. XXX. p. 422.

Digitized by Google

with the periphery of the armature core." This allowed a thoroughly mechanical construction, and gave entire satisfaction, the actual results having so far borne out expectations, and no one of those built has shown any signs of weakness or of deterioration. The motor occupies the front half of the bogie truck. The magnets (which are of the horizontal "double-circuit" type) are maintained in correct relation to the armature axle by two cast-iron flitch frames, carried by forged extensions of the magnet yokes (Figs. 3, 4 and 5). The weight of the magnets is taken off the axles by means of adjustable springs suspended from the bogie-frame and attached to brackets at each end of the motor. To retain the magnets in a correct horizontal position, a lever arm projects from the inside end of the motor, and is attached to the bogie-truck beyond the bolster by rubber spring pads, top and bottom. The motors are series-wound, and develop 40-H.P. for any length of time without undue heating. The armature resistance is 0·67 ohm, and that of the field-magnet coils is 0·37 ohm. A large torque effort in this case was the chief object aimed at, the motors being coupled at the time of starting in series across the 500 volts without any resistance in circuit. The tractive force of each motor at the rim of the wheels (2ft. 9in. in diameter) with 100 amperes exceeds 1,450lb. (about 87lb. per ton of trains). Fig. 6 gives curves of torques and saturation of the magnets with various currents. The weight of each motor with its axle, but without the wheels, is 3 tons, and that of the motor-truck complete is 5 tons 7cwt.

That these motors will stand any stresses they are likely to be called upon to bear has been proved, and this fact has been found to be of great service in actual running; for, before the drivers were properly educated to their work, they frequently, on finding any difficulty with either motor on the train, such as brush-leads working loose, or brushes making bad contact, cut that motor out of circuit by means of a plug provided on the driving switch, and continued the traffic with one motor to the end of the line.

Control of the Trains.—The cars are furnished with both compressed-air and hand brakes. The switch gear is so arranged that when two cars are coupled together to form a train (Figs. 7 and 8, p. 520 ante). there is a driving-box at each end. But only one set of handles is provided for manipulating the switches, and these the driver takes with him from one end of the train to the other, when he arrives at the end of the journey. Either the driving or trailing motor can be plugged into circuit at will. The switches comprise a magnetic cut-out switch for making and breaking circuit, a driving switch which arranges the two motors, first in series and then in parallel (with a resistance in series with each), and, to attain a speed of 30 miles per hour as required by the specification, inserts a resistance in parallel with the field windings. A reversing switch is also interlocked with the driving switch, which must be turned to the series position before the currrent can be reversed.

Lighting and Signals.—The stations are lighted by 50-volt glow lamps worked by accumulators fixed underneath the platforms. The signals are automatic, and are worked from the same source. These accumulators are charged from the main dynamos in two loops, those of the northern portion of the line being charged in series in one loop, and those of the southern end in another one. At each station two independent batteries are fixed, coupled to a switchboard, so that either battery can be connected to the charging, or to the lighting circuit. These switches are so interlocked that both batteries can never be cut off the station circuit at the same time, although both can be run in parallel on to it. In this

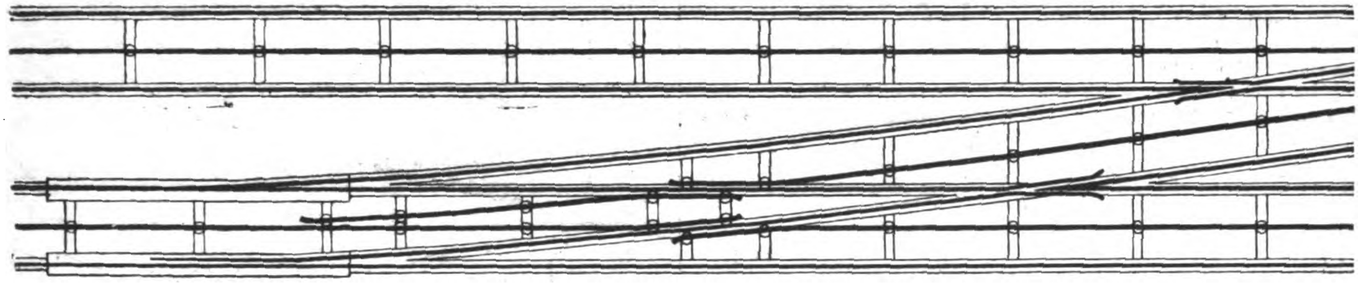

FIG. 2.—Plan of cross-over road showing method of bending the charged conductor (thick black line) to avoid passing the rail return.

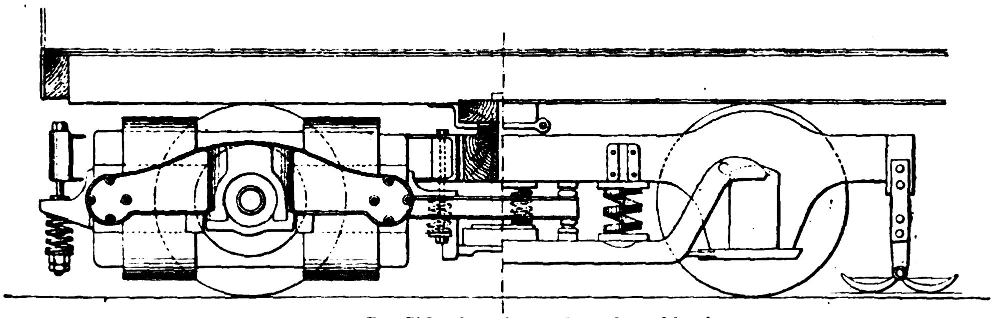

FIG. 3.—Side elevation and section of bogie.

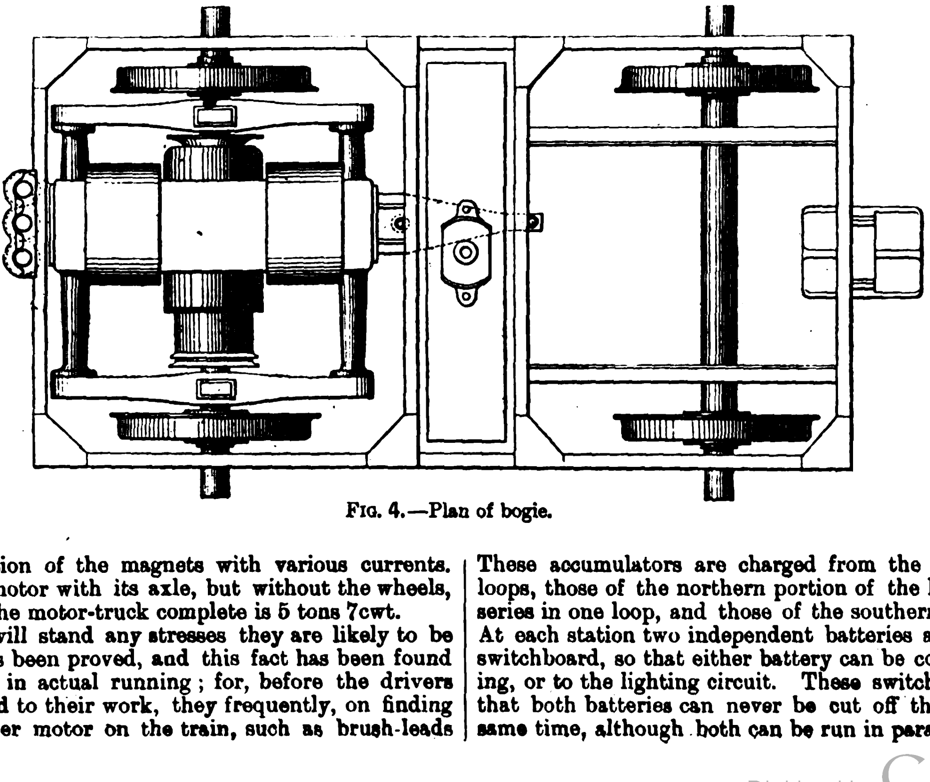

FIG. 4.—Plan of bogie.

Digitized by Google

case the charging-main is short-circuited through the station so as not to interrupt the circuit for the batteries at the other stations. The batteries can never be on the charging circuit and on the station circuit simultaneously. These conditions were required by the Board of Trade.

Power at the Generating Station.—The efficiency of indicated horse-power to electrical horse-power on the line is very high, and results are given of special tests with carefully calibrated instruments. For this purpose No. 1 engine and dynamo were used. This engine had been running for some weeks, and was in thorough working order, the valves being carefully adjusted to give the best diagrams. The tests were taken after the engine had been running the traffic all day, when the load was transferred to a water-resistance tank. They lasted over three hours and a half, volts, amperes, and speed being kept constant, and readings and diagrams taken every half-hour. The details are given in the Appendix, and the diagrams of this and of each of the other engines in the

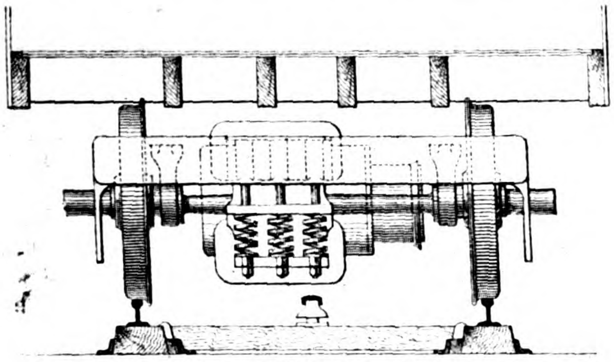

FIG. 5.—End elevation of bogie.

station running under ordinary conditions are given in the Paper. These diagrams were taken on both cylinders simultaneously by Tabor indicators. The electrical current was measured by a Kelvin hecto-ampere balance, and the pressure by a Kelvin electrostatic voltmeter. The results of the tests are :—

	Inches.
Diameter of high-pressure cylinder.....................	15½
,, ,, low-pressure ,, ...	31
Length of stroke	36

Mean efficiency (E.H.P. to I.H.P.), 88 per cent.
Coal consumed, 4,032lb.
Total E.H.P. hours, 1,195.
Coal per E.H.P. hour, 3·37lb.
Coal per I.H.P. hour (efficiency 88 per cent.), 2·96lb.

These results are eminently satisfactory, and are borne out by the low coal consumption in practice, of which mention will be made later.

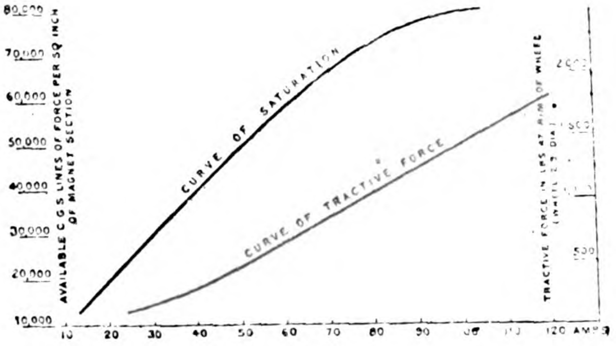

FIG. 6.

Curves are given (Fig. 7 being a sample) showing the power absorbed by a train during an experimental run covering the length of line at present open (5⅛ miles) in 24min. 57sec., with intervals of 25sec. stoppage at the stations, or an average running speed of 15·1 miles per hour. Also during one journey performed in 23min. 47sec., or at the rate of 16·1 miles per hour.

The particulars of these trials are :—

MARCH 5, 1893. FIRST JOURNEY.

Herculaneum to Alexandra (return). One train on line.

Loaded with 8 tons (iron weights).
Total time on journey, 24min. 57sec.
,, ,, current is on car, 17min. 7sec.
,, ,, train is standing, 4min. 35sec.
Total distance run, 9,030·4 yards = 5 miles 230 yards, say 5⅛ miles.
Average speed while running, 15 miles per hour.
,, ,, including stops, 12·3 miles per hour.
Average current per train while running, 82·7 amperes ; including stop, 67·3 amperes.
,, E.H.P. per train while running, 54·4 E.H.P., including stop, 44·4 E.H.P. = 33,300 watts approximately.
,, electromotive force, 485·2 volts on car.

MARCH 5, 1893. SECOND JOURNEY.

Herculaneum to Alexandra (return). One train on line.

Loaded with 8 tons (iron weights).
Total time on journey, 23min. 47sec.
,, ,, current is on car, 15min. 18sec.
,, ,, train is standing, 4min. 40sec.
,, distance run, 9,030·4 yards, say 5⅛ miles.
Average speed while running, 16·1 miles per hour.
,, ,, including stops, 13 miles per hour.
,, current per train while running, 90·8 amperes ; including stops, 73 amperes.
,, E.H.P. per train while running, 57·1 E.H.P., including stops, 46 E.H.P. = 34,500 watts approximately.
,, electromotive force on car, 484 volts.

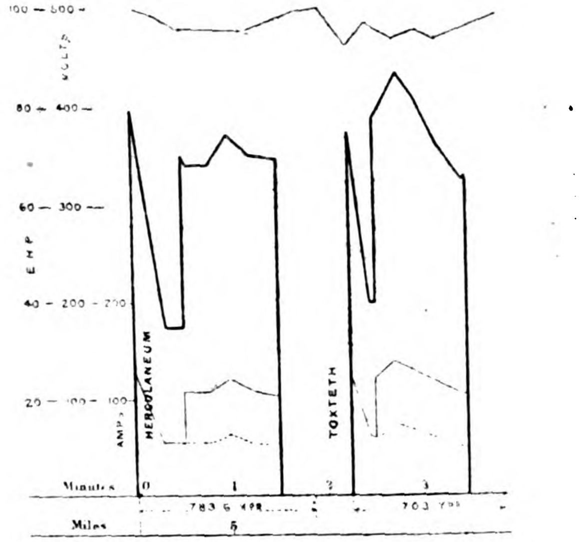

FIG. 7.

The weight of a car complete without passengers is 15½ tons. For the test each car was loaded with 4 tons, making the total weight of the train 39 tons. The average power absorbed was 44·4 E.H.P. at 15·1 miles per hour, and 46 E.H.P. at 16·1 miles per hour.

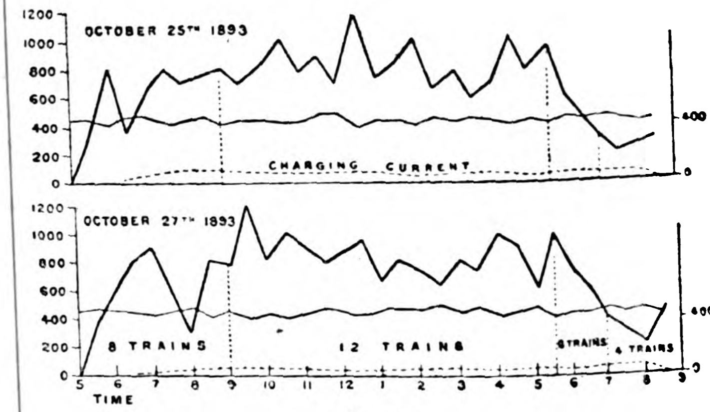

FIG. 8.

To compare this with the conditions of actual running, curves taken from the daily log-sheet are also given (Figs. 8 and 9) of the output from the generating station. Readings of volts and amperes were taken every half-hour. These readings include the current used for charging the station-batteries, and for a motor at the car-shed to drive air-compressors, &c. The battery charging current is also given. These curves show the current taken at different times of the day when the train-service varies ; and the advantage of a large number of trains in reducing the maximum current per train is at once apparent. When seven trains are in service, the maximum current attained is approximately 860 amperes, or, say, 123 amperes per train. This is twice the average current required by each train, whilst with twelve trains the maximum current from the generating station is 100 amperes per train, or only about one and a-half times the average current. Making the necessary deductions for battery charging and car-

Digitized by Google

shed, the average demand for power continuously, with twelve trains running, is 37 E.H.P. per train. A plan of the line, with the distances between the stations, is given in Fig. 1, p. 493 ante.

A comparison of the consumption of coal when the number of trains is varied is interesting. During the month of April and part of May there were seven trains on the line, giving a ten-minutes' service from 5.10 a.m. to 6.40 p.m. During this period the coal burned was 22·55lb. per train mile. This includes coal for all purposes, no deductions being made for charging the station-batteries, &c.

From June to the beginning of October the train service has been as follows:—

5. 0 a.m. to 9. 0 a.m. eight trains in service.
9. 0 a.m. „ 5.30 p.m. twelve „ „
5.30 p.m. „ 7. 0 p.m. six „ „
7. 0 p.m. „ 8.30 p.m. four „ „
giving a five-minutes' service from 9.0 a.m. to 5.30 p.m.

The coal used for all purposes per train mile has been—

	Lb.
April	25·16
May	20·03
June	18·97
July	18·27
August	16·95
September	17·20

These figures show a continual steady decrease in fuel consumption. That for August is abnormally low, due to extra traffic during the holiday week, the car mileage on the 7th of that month being 21 per cent. greater than usual. On that day the trains carried 48,000 passengers, each train during the middle part of the

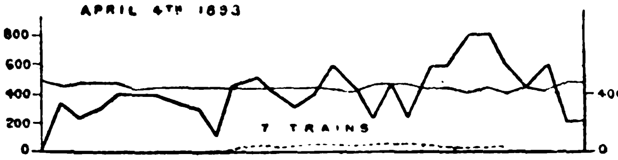

FIG. 9.

day being loaded with over three hundred people. The average weight of slack burned during the four months of June, July, August, and September, inclusive of all battery charging and power at the central station and car shed, was slightly less than 17·8lb., or, allowing for energy expended otherwise than on the trains, it may be taken at 17lb. per train mile.

TABLE SHOWING COAL CONSUMED PER KILOWATT-HOUR, &c.

—	Kilowatts generated.	Lbs. per kilo-watt-hour.	Lbs. per E.H.P.-hour.
April	69,954	8·40	6·32
May	86,627	6·90	5·17
June	97,789	7·10	5·30
July	109,909	6·70	5·00
August	117,843	5·95	4·44
September	119,328	5·81	4·34

During four days in June, owing to the dock from which condensing-water is drawn being emptied, the engines ran non-condensing, and an additional boiler was required.

The coal used is small Lancashire slack, having the following composition:—

	Per cent.
Fixed carbon	70·08
Volatile hydro-carbon	16·47
Sulphur	1·92
Moisture	3·01
Ash	8·51

Its calorific value is approximately 75 per cent. of that of best Welsh coal. The price of the slack which was used until the latter part of August was 5s. 10d. per ton; but since that date, owing to the strike in the coal trade, coal has been procured from various sources at prices ranging up to 17s. 6d. per ton.

Cost of Working.—Under their agreement, the contractors engaged to run the service of trains for the Liverpool Overhead Railway Company, and to supply all power, maintenance, drivers, superintendence, &c., if required, for a period of two years, for the sum of 3½d. per train-mile, which was estimated upon an average daily running of 2,400 miles. At the present time only 5¾ miles of line have been opened for traffic, and the contractors have received 4d. per train mile, as with a five-minutes' service, the total train mileage is necessarily decreased on the shorter line. For current to charge the station batteries 7d. per unit is received, which includes the maintenance of lighting and signal plant. In the Table on next page are given figures analysed from the actual working costs during the months of July, August, and September.

The increased cost of running during August and September is fully accounted for by the item of coal; and, taking into consideration the fact that the Overhead Railway Company has not employed so rapid a service as was at first anticipated, the average running per day being only about 1,350 train miles, the figures indicate most favourable results; as, even with this mileage, the trains were run at a fair profit for July and August, and it is evident that, with coal at a normal value, the line can be run at a cost within that guaranteed by the contractors.

In designing and executing the work described, the Author has received valuable assistance from Mr. J. H. Woodward, Assoc. M. Inst. C.E., and Mr. E. S. G. Rees, members of his staff, and from Mr. C. A. Rowlandson, M. Inst. C.E., who acted as the contractors' representative; and he further desires to acknowledge his indebtedness to Mr. S. B. Cottrell, Assoc. M. Inst. C.E., the Engineer and Manager of the Liverpool Overhead Railway Company.

Cost of Working, including the Lighting of Stations and the Signals.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The Corporation of South Shields invite tenders for a large quantity of plant, apparatus, and instruments, of which particulars are given in our advertisement columns. Copies of specifications, &c., can be obtained at the Borough Electrical Engineer's Office, South Shields, on and after the 17th inst.; and tenders must be sent in to Mr. J. Moore Hayton, Town Clerk, not later than October 31st.

——— The County of London and Brush Provincial Company require tenders for the supply and delivery of about 700 tons of 2in. and 2½in. cast-iron spigot and socket pipes. Further particulars can be obtained of Mr. A. J. Lawson, engineer and manager of the Company.

——— The Corporation of Cardiff invite tenders for wiring the Town Hall and market buildings, and supplying and fixing cables, casings, &c. Tenders must be sent in by the 12th inst.

——— The Corporation of Portsmouth invite tenders for the purchase of certain electrical plant at the Town Hall, Portsmouth, for which tenders have to be in not later than 6 p.m. on the 22nd inst.

TENDERS ACCEPTED.—The tender of Messrs. T. Scott and Co., of Birmingham, has been accepted by the Wolverhampton School Board for the installation of the electric light in the Walsall-street New School, for the sum of £233. 10s.

——— As stated in our issue for the 24th ult., the tender of Messrs. Crompton and Co. has been accepted by the Southampton Harbour Board for work in connection with the lighting of the Town Quay. Twenty-four tenders were received by the Harbour Board.

——— The Reading Electric Supply Company (Limited) have accepted the tender of Mr. E. Blackwell, of Reading, for basement, &c., works, at their central station, Western-road.

——— The tender of Messrs. Paterson and Cooper has been accepted by the Worcester Watch Committee for wiring the generating station at Powick for the sum of £206.

——— The tender of Mr. Grossmith, of Portsea, has been accepted for the electric light fittings for the new technical school.

CONTRACTS OPEN.—Our readers are reminded that the tenders for the supply of junction boxes, covers, and other castings for the Cheltenham Corporation, in connection with their electric lighting scheme, are due to-morrow, September 8th, as are also the tenders for the lighting of the outside of the Empire Palace of Varieties, Westgate, Barnsley. The tenders for the supply of arc lamp-posts (contract No. 18) have to be sent in to the Corporation of Edinburgh by the 17th inst. Particulars of the last-named contract may be obtained of Prof. A. B. W. Kennedy, 14, Old Queen-street, Westminster, S.W., or at the offices of the resident engineer, Dewar-place, Edinburgh.

APPOINTMENTS VACANT.—The Vestry of St. Mary, Islington, require a road foreman to take charge of a gang of men engaged in the laying of conduits and cables and other work in connection with the electric lighting of the parish. Applications have to be sent in to the electrical engineer, the Vestry Hall, Upper-street, Islington, N., not later than the 10th inst.

——— The Gas Committee of the County Borough of Salford require a properly qualified mechanical and electrical engineer to act as clerk of the works and superintend the erection of central station plant. Some further particulars are given elsewhere; and applications must be sent in before 5 p.m. on September 15th.

SALE OF ELECTRICAL ENGINEERING WORKS AND PLANT.—On Tuesday last the important electrical engineering works at Westminster, lately in the occupation of Messrs. Latimer Clark, Muirhead and Co., came under the hammer. Messrs. Fuller, Horsey, Sons and Cassell, of Billiter-square, conducted the auction. For the leasehold interest of the premises, which was held for a short time at a ground rent of £400 per annum, no bid was obtainable, and the sale of the plant and machinery, stock and stores, was immediately proceeded with, and the prices obtained, considering the present depressed condition of trade ruled exceptionally high. The small hand lathes from 3in. to 4½in. centres fetched up to £6 each, and the larger lathes in proportion. The 6in. screw-cutting lathe we noticed realised £40, Brown and Sharp's No. 1 size milling machine £91, and the Taylor and Hobson's engraving machine £28. The moulding and planing machines in the pattern-makers' shop, being old fashioned, went at proportionate prices. As regards steam power, the Galloway boiler, 6ft. diameter, 18ft. long, was knocked down at £136, and a 16in. centre screw-cutting lathe, with 15ft. bed, realised £150. The sale will be continued this day (Friday).

PLANT FOR SALE.—The sale is announced of the whole of the stock, at 88, Queen Victoria-street, and at Bradford, Glasgow, and Chiswick, of Woodhouse and Rawson United (Limited). Full particulars can be obtained of Mr. F. D. Leslie, receiver and manager, 74, Coleman-street, E.C.

LIQUIDATIONS.—A meeting was held at Birmingham last week of the creditors of Messrs. Woodall and Son, glass manufacturers, of the St. George's Glass Works, 10, Great Hampton-street, and Barr-street, Birmingham, at which a committee of creditors was formed to carry out the conditions of a deed of assignment by which the debtors have conveyed their estate to the trustee (Mr. W. N. Fisher, of 4, Waterloo-street, Birmingham, chartered accountant) upon trust to collect, sell, and realise same, and divide the net proceeds amongst the creditors. The trustee has the power to carry on the business in the meantime. Creditors in person or represented are requested to send their assent to the arrangement to the trustee at once.

——— From a summary of the Liquidator's accounts in the matter of Poole and White (Limited), just issued by the Liquidator, it would appear from the accounts from September 15, 1893, to March 31, 1894, that calls have been made by the liquidator to the amount of £200, and costs have been incurred to the amount of £123. 5s., leaving a balance of £76. 15s. Creditors and contributories are informed that any further information can be obtained on application to the Liquidator, Mr. E. Wilding, 2, Clement's-Inn, London, W.C.

——— A first and final dividend of 11s. 6d. in the £ is payable at the Official Receiver's office, 24, Railway-approach, London Bridge, S.E., in the matter of Moses Humm, of 8, West-bourne-road, Forest Hill, London, S.E.

——— The first meeting in the matter of P. H. Pitman, trading as P. Pitman and Co., hydraulic, electrical and general engineers, 3, Brook-road, Cheadle, Cheshire, takes place to-day at the Official Receiver's Office, Stockport, at one o'clock. The examination of the bankrupt takes place at the County Court, Stockport, on October 18th, at 11:30 o'clock.

LISTS OF CREDITORS.—The following is the list of the principal creditors in the failure of George Forrest and Son (Limited), of 2, Great New-street, E.C. :—

Bankers' Claims	£930	10	0	Highton and Co.	£34	19	6
S. C. Cupes	228	0	0	Lithanode and General Electric Company ..	22	5	0
C. S. Drighton	87	12	0	Russell, Innes and Son (Limited)	62	16	3
R Dyas	20	10	0	T. Smith and Co.	48	5	10
Edison Swan United Electric Light Co	36	14	11	W. Sugg & Co.(Limited)	21	17	2
Ellis&Sons, Birmingham	40	8	6	Smith and Sons	18	16	2
T. Glover and Co	21	12	6	H. Selim	93	5	0
General Electric Co. ...	18	10	11	Shaw Bros.	209	0	0
W. T. Glover and Co., Salford	17	10	6	J. Wilkinson and Sons..	21	0	6

(Remainder of London).

——— The following list of creditors in the winding-up of the Collier Audible Telephone Syndicate (Limited) is issued :—

A. R. Bennett, Manchester	£20	0	0	W. Heys, Manchester..	£87	0	0
A. T. Collier, St. Alban's	66	14	7	Leslie Antill & Arnold, London	67	6	10
Flocton & Co., Sheffield	20	19	8	H. Matthews, Manchester	14	12	8
General Electric Co. ...	23	14	3	David Moseley & Sons, Manchester	21	9	0
W. T. Glover and Co., Salford	10	13	0	Nicholson, Graham and Graham, London	99	4	0
W. B. Haigh and Co., Oldham	23	19	9	Shepherd and Sons, Cleckheaton	55	10	0
Haseltine, Lake and Co., London	19	17	0				

——— In the failure of Arthur Shippey, electrical engineer, of 13, King-street, Cheapside, London, E.C., the following is the list of principal creditors :—

Edison & Swan United Electric Light Co......	£130	0	0	Hepburn and Son	14	10	0
The Electrician Printing and Publishing Co....	12	10	0	*Industries*, Manchester.	30	0	0
Gartside, J., Ashton-under-Lyne	158	0	0	Johnson, Mathey and Co.	£33	0	0
General Electric Company	18	18	0	Nettlefold and Sons	157	0	0
Gulcher Electric Light and Power Company.	160	0	0	Pieper and Sons, Liege.	80	0	0
				M. Politzer	30	0	0
				Rooks and Co.	113	0	0
				Electrical Engineer	18	0	0
				Tongue and Birkbeck ..	33	0	0

Fully Secured Creditors.

Bolling and Lowe	85	0	0	P. Mason	200	0	0
Davis and Son	45	0	0	Mackey, Mackey & Co.	240	0	0
I. E. A. Gwynne	1,360	0	0	Reed and Son	30	0	0
Hepburn, Son & Cutliffe	179	0	0	R. Stuart	91	10	0
J. Garnham	100	0	0	L. A. Bailon	75	0	0
F. Hill	61	11	8	Bankers' claims	120	0	0
Lovering and Co.	55	0	0				

Partly Secured Creditors.

J. Bennett (exors. of) ...	50	0	0	Liabilities on bills	300	0	0

(Remainder of London).

DISSOLUTION OF PARTNERSHIP.—The partnership existing under the firm of John Sykes and Sons, machine makers, of Turnbridge, Huddersfield, has been dissolved. Debts will be paid by Mr. E. Sykes, who continues the business.

Digitized by Google

DISSOLUTIONS OF PARTNERSHIP.—The partnership hitherto existing between Frederick Nettlefold, William Richardson, and Edward Nettlefold, trading as Richardson, Ellson and Co., electric light fittings manufacturers and mediæval metal workers, of Brownlow-street, High Holborn, London, W.C., has been dissolved.

——— The partnership between Samuel Barton M'Clellan and Walter Samuel Newbould, electrical engineers, of Ludgate-hill, London, E.C., has been dissolved.

——— The partnership existing between J. H. Cundall and Messrs. Cundall and Venner, Cannon-street, London, E.C., consulting civil and electrical engineers, has been dissolved.

MARTINY (LIMITED).—The hearing of the petition for the winding-up of this Company is to take place at the Royal Courts of Justice, Strand, W.C., on October 14th. The petition has been presented by Messrs. W. F. Malcolm and Co., of 36, Leadenhall-street, E.C.

TECHNICAL EDUCATION.—The London County Council Technical Education Board will in October proceed to award not more than 200 junior county scholarships in secondary education, of which 130 will be for boys, and 70 for girls. The object of these scholarships is to secure for promising pupils the necessary pecuniary assistance to enable them to continue their studies in technical and manual instruction. Further particulars can be obtained at the Council Offices, Spring-gardens, London, W.C.

THE NEW LINE INTO LONDON.—Tenders are now invited for the construction of the extension of the Manchester, Sheffield, and Lincolnshire Railway into London. The line will be 112 miles in length, and its total cost is estimated at £6,500,000. Sir Douglas Fox is engineer-in-chief of the line, the contracts for which are divided up into seven parts.

LEGAL.—BRAULIK v. SHARP AND KENT.—In the City of London Court, Mr. George Braulik, of Upper Thames-street, E.C., claimed the sum of £2. 2s. 6d. for electrical goods supplied to the defendants, Messrs. Sharp and Kent, electrical engineers, carrying on business at Victoria-street, Westminster, S.W. Mr. Money-Kent, one of the defendants, said that the goods were bought "on appro," and the plaintiff's traveller admitted taking the order on those terms, but said it was explained at the time that if the defendants desired to keep the goods for a fortnight or three weeks the plaintiff would be willing to allow this to be done. The defendants had, however, kept the goods for twelve months. Mr. Kent said he bought the goods "on appro," which meant, in the electrical trade, that if they were not sold they were to be returned. Mr. Commissioner Kerr, before whom the case was heard, said he did not know the meaning of the term "on appro" in the electrical trade, and decided to adjourn the case until Oct. 4th for trial before a jury.

MESSRS. JOHNSON AND PHILLIPS.—This firm report renewed activity in their cable department, particularly in the rubber shops in the manufacture of house-wiring cables and wires. It is noticeable that the majority of engineers now specify that only stranded conductors shall be employed.

CROMPTON'S POCKET COMPENDIUM.—A new edition of Messrs. Crompton and Co.'s pocket price list and useful formulæ has just been issued. The printed matter bears date July, 1894, although the lettering on the cover gives January. The price-list pages are *fac-simile* reductions of the large catalogue issued by the firm, and the work of reduction is very creditable. The little book contains explanatory notes on a variety of subjects, price lists of combined engine and dynamo plants, travelling cranes, hoists, instruments, apparatus, &c. As the reduction of the pages from 11in. by 8½in. to 4¼in. by 3⅜in. makes the reading difficult, a microscope is issued with each copy, for which a pocket is provided in the cover. Besides price list, telegraph code, &c., many useful notes and formulæ and a good wire table are given. We can vouch for the popularity of the previous edition of the pocket catalogue and formulæ, and hope similar success will attend the new venture.

COOKING BY ELECTRICITY.—Messrs. Crompton and Co. are showing electrical heating and cooking at the Food and Cookery Exhibition, Manchester, and their demonstrations are creating general interest. Several dinners have been cooked, and the new electric grill, recently brought out, is stated to cook to a nicety at a small expenditure of current.

ANOTHER WORLD'S FAIR.—An official movement is on foot to arrange for another great World's Fair, to be held in New York in 1898, to which the Municipal and State authorities have given their approval. The business houses of the city give the scheme only lukewarm support, as experience has proved that the few brief weeks of extra business is followed by a long period of depression.

AUCKLAND (NEW ZEALAND).—The City Council have been invited to a conference with the Harbour Board with a view of arranging for combined action in the matter of the electric lighting of the town and harbour.

BELFAST.—The Corporation have agreed to the proposal of the Electric Light Committee on the subject of rebates to be allowed to consumers of electric current, these rebates amounted to 2½ per cent. on quarterly accounts of £2. 10s. to £5 to 17½ per cent. on accounts of £70 and upwards. The Committee's report states that the works in connection with the central station and the laying of the mains are progressing satisfactorily, and that some of the engines have undergone preliminary tests.

BRISTOL.—The applications for the electric light from the Corporation mains is far in excess of expectations. During last week orders for no less than 1,000 lamps were received, although the dark evenings have not yet set in. It is intended to use about 500 incandescents to light the museum in the Queen's-road.

CEYLON.—It is stated that the introduction of the electric light into Ceylon is attracting much attention, and planters are making serious inquiries into the probable cost of the substitution of electric light for the kerosene lamps now used in their factories.

CHELMSFORD.—The Board of Trade have given the Town Council sanction for the erection of overhead electric lighting wires in certain new streets, &c., on condition that in the event of certain wires being placed underground, a portion of those overhead now sanctioned are also to be put underground. A number of up-to-date transformer pits are being provided for the underground work. The street lighting, by both arc and glow lamps, appears to give great satisfaction. Electric fire alarms have been erected throughout the town, and are reported to have proved successful.

CHURCH LIGHTING.—The Duke of Norfolk has recently presented the City of Norwich with a handsome Roman Catholic church, erected on the most commanding site in the city from the designs of Sir Gilbert Scott. The interior is 150ft. in length and 64ft. in width. The church is lighted thoroughout by electricity.——St. George's Church and the Roman Catholic chapel, Sansome-street, Worcester, are to be lighted electrically from the Corporation mains.——The vicar of Jesmond church, Newcastle-on-Tyne, has recommended that the electric light be introduced. For this, and other improvements to be made, a sum of £550 is estimated to be required.

DARLINGTON.—In 1890 the Corporation obtained powers for lighting the borough by electricity. No action has been taken since that time by the local authorities, who are, however, still anxious to retain the powers, and have by deputy interviewed the Board of Trade upon the subject. Mr. Hopwood has informed the Corporation that the powers will not be withdrawn, and as the Corporation desire to enlarge the proposed lighting area, all possible assistance will be given by the Board of Trade.

DOLGELLY.—The Local Board have received a communication from Messrs. Hall and Company with regard to the proposed purchase of the electric lighting plant. It was, however, decided that as arrangements were pending for the lighting of the town by gas the Board were not prepared to make any offer to Messrs. Hall and Co.

DOVER.—The local electricity supply company have issued a notification that they hope to be in a position to supply current for light and power by the end of the current month.

DUNDEE.—Messrs. Urquhart and Small have sent in their report to the Gas Committee on the addition which Mr. W. H. Brownlee, the electrical engineer, proposes should be made at the central station. The report points out that the amount of current applied for already amounts to nearly 3,500 amperes, of which 80 per cent. may be required at one time, so that the total plant at present available (with an actual capacity of about 3,000 amperes) would not prove sufficient in the event of a breakdown or a machine going out of repair. It is, therefore, recommended that additional plant should be put down, consisting of a 560-ampere dynamo and a 200-I.H.P. engine, with an additional boiler. This additional plant is estimated to cost about £2,500. The Gas Committee recommend the adoption of the report, but that the new boiler and portion of the engine power be dispensed with.

THE ELECTRIC LIGHT IN JAPAN.—The Foreign Office has recently issued an interesting report by Mr. Hensley, a representative of this country in the Mikado's country. The report states that there are now eleven electric light companies in full work, with an aggregate paid-up capital of $1,674,000 out of an authorised capital of $2,477,000.

ECCLES.—The Town Hall, Tramways, and Electric Lighting Committee have visited Whitehaven to inspect the electric lighting arrangements in that town, but report to the Town Council that they are not in a position at present to make any recommendation on the subject.

ELECTRIC TRACTION IN ROUMANIA.—The town of Jassy is about to be provided with a system of electric tramways, the municipal authorities having, it is stated, recently decided to grant a concession to private parties for the establishment and operation of such a system. Particulars of the proposed concession may be had from the Town Hall, Jassy.

ELECTRICITY.—"Electricity is in its Infancy."—*Financial News.*

Digitized by Google

EMBEZZLEMENT.—Isaiah Parton, aged 29, was sentenced at Brighton last week to four months' imprisonment with hard labour for embezzling various sums, the moneys of the Brighton and Hove Electric Light Company (Limited), and also falsifying the books of the Company.

FOOTBALL BY THE ELECTRIC LIGHT.—The electric light is now frequently used in the north to enable football matches to be played at night. On Tuesday last a match between the Rochdale Hornets and Rochdale and District was played by the aid of the electric light before 3,000 spectators, and was concluded without hitch or accident.

GOOLE.—An extensive range of buildings for the new Market Hall is to be shortly erected from plans prepared by Mr. Tenant, of Pontefract, at an estimated cost of about £12,000. The buildings are to be fitted throughout for the electric light.

GLASGOW.—At a meeting of the Joint Committee appointed to consider the cost of lighting the public thoroughfares by electricity, the Electric Lighting Committee represented that as the cost of each of the public lamps is £30 per annum it would be impossible to continue the old charge of £20 per lamp per annum, and the Committee proposed that £26 should be the charge fixed in future. The Sub-Committee decided to report the matter to the Watching and Lighting Committee for consideration.——It is considered probable that the renewed applications for the extension of the electric lighting mains to the Park-terrace and Park-circus district, will be granted, and the Sub-Committee on electric lighting have recommended that the mains be extended, the estimated cost being £6,000.——The Gas Committee have decided to make no increase or decrease in the price of gas or electric light. The former remains at 2s. 6d. per 1,000, and the latter at 6d. per unit.——The Corporation Water Committee will shortly be prepared to supply hydraulic power for hoists and other purposes at a rate considerably below that charged by London companies.

HERTFORD.—In reference to the introduction of the electric light into this town a special meeting of the Town Council was called last week to decide upon the policy to be adopted. After some discussion, it was decided to call a public meeting to consider the matter.

ILKLEY.—A Local Government Board inquiry has been held here into an application for sanction to borrow £2,600 for improving and enlarging the gas works recently acquired by the Local Board at a cost of nearly £60,000. The application was opposed by Mr. Gaunt, who stated that the electric light was badly wanted at Ilkley, and it was more than likely the ratepayers would very soon insist upon having it. He considered, therefore, that the Local Board would have been well advised to have commenced by adopting the electric light, and if that had been done they would have purchased the gas works at a much lower sum than had now been paid for them.

INVERNESS.—The Town Council have received intimations from two companies of their intention to apply for Provisional Orders to supply the town with the electric light. It was decided to refuse the consent of the Council to both applications, and to remit the matter to the Law Committee with a view to considering the town's position in the matter.

ISLE OF MAN.—A Liverpool journal states that the success of the Douglas and Laxey electric tramway has led to a proposal to construct another electric line from Laxey, the terminus of the Douglas Company's line, to Snaefell, and that the construction of the roadway is to be commenced immediately.

LANCASTER.—It has been decided to add 10 Crompton arc lamps to the electric lighting of the town market.

LEICESTER.—Alderman Lennard, at the last meeting of the Corporation, in moving the adoption of the Gas Committee's report with reference to the electric lighting undertaking, referred to a circular issued by the gas department some three years ago, in which it was stated that consumers using electric current would have to pay between two and three times as much more for light as by using gas. That statement was made at a time when lamps were much dearer and less efficient than now, and such improvements and reduced prices had taken place that electricity might be looked upon as about equal in cost to gas, and he did not think that any shopkeeper would find his bills heavier at the end of the quarter if electricity were used in place of gas, and there were many important advantages outside the question of actual cost. They had a considerable demand for current up to the present time, although the undertaking was not nearly complete. Current equal to about 1,300 16-c.p. lamps had been applied for. Although they had decided to fix the price at 6d. per unit, there was no finality about this charge, and he hoped that the time would come when they would be able to propose an appreciable reduction in the price per unit.

LINCOLN.—The Town Council have decided to oppose the application of the Brush Provincial Company for a Provisional Order to light the district by electricity. The Council have expressed themselves prepared to undertake the work of lighting the district by electricity "as soon as they are satisfied that the true interests and advantage of the citizens demand such a mode of lighting."

MELBOURNE (AUSTRALIA).—In connection with the electric lighting of this city the City Council have accepted the offer of Messrs. G. and C. Hoskins, to machine dress 217 35ft. poles, and 1,127 30ft. poles, and to fit them with such arms as may be required at £1. 9s. 3d. and £1. 4s. 3d. respectively per pole, or a total cost of £1,683. 17s. A plan and specification has been approved for the supply and erection of iron columns, and the supply and laying of iron pipes in connection with the placing underground of the electric light wires in front of the Equitable Life Assurance Society's buildings at the corner of Collins and Elizabeth-streets, the cost of which will be defrayed by that society. It has been decided to invite tenders for carrying out the work according to the plans submitted. The tender of Messrs. Glover and Nixon for the sum of £58. 15s. has been accepted for the supply of 300 cast-iron pole irons required in connection with the electric lighting of the city.

MOTHERWELL.—On Tuesday last the Motherwell Commissioners had under consideration a notice from the Scottish House to House Electric Lighting Company intimating their intention to apply to the Board of Trade for a Provisional Order, and asking the consent of the Commission to the proposal. On the recommendation of a Special Committee, consent was not given, as the Commissioners were already in consultation with Mr. Mavor, of Glasgow, with a view to formulating a scheme for lighting the town by electricity.

NEW SWINDON.—A proposal to apply for an Electric Lighting Order has been referred to the Electric Lighting Committee of the Local Board.

PORTSMOUTH.—The report of the Electric Lighting Committee was dealt with at this week's meeting of the Town Council. The report states that, estimating the present rate of increase in the applications for electric current is maintained, the plant at present provided will be altogether insufficient to meet the demand, and that it will not be advisable to await this increased demand before taking steps to procure additional plant and apparatus. For these additions it is estimated that a further sum of £6,000 will be required, and it is therefore recommended that an application be made to the Local Government Board for sanction to borrow a further sum of £20,000, but only £6,000 of this sum to be at present obtained. A statement of the expenditure up to date accompanies the report. The Finance Committee comment upon the above report, and recommend that application be made for only £6,000, the amount immediately required. On Saturday of last week applications were made for no less than 886 16 c.p. lamps. The number already in use, and to which that 886 must be added, is 3,740. The rate of progress will be shown by the following fortnightly record:—June 5th, 2,094; June 20th, 2,508; July 4th, 2,863; July 18th, 3,087; August 1st, 3,517; August 15th, 3,674; August 28th, 3,740. Soon, too, the technical school and the public baths will have the system laid on, and they will raise the total number of 16-c.p. lights in use to about 5,000. That number will keep in full working the whole of the dynamos at the central station, leaving no machinery to fall back upon in case of contingencies.

ST. GEORGE'S (LONDON, W.).—On the ground that the Company have no powers to lay electric light mains in St. George's Parish, the Vestry have declined to give permission to the St. James and Pall Mall Company to lay an electric main in New Bond-street, W.

SUNDERLAND.—The exhibition which is shortly to be held here is to be lighted throughout by electricity.

THE BRAZILS.—It is stated that a number of Santos capitalists have offered to illuminate the city of Santos by electricity.

THEFT.—The Hungarian, Edward Morway, who was remanded last week, was sentenced at Glasgow on Tuesday last for swindling Sir William Arrol. The prisoner represented that he had a valuable electrical patent, and Sir William took him into his employment, fitted up premises for him at great expense, and purchased a quantity of expensive material, including £200 worth of platinum. It was only when the platinum began to disappear that the fraud was detected.

THE MIDDLE TEMPLE.—During the Long Vacation the library and the famous Elizabethan Hall of the Middle Temple has been fitted with the electric light. This hall is one of the few remaining historic buildings in London associated with the name of Shakespeare.

PRESTON.—The Markets and Town Hall Committee of the Town Council have appointed a sub-committee to consult with Dr. Hopkinson as to the lighting by electricity of the Town Hall and Public Hall.

TRAMWAY CAR LIGHTING.—The London Tramway Company have decided to use the electric light on the cars running over their Streatham Hill route. The lamps are now being fitted to the cars.

Digitized by Google

ULVERSTON.—The Rural Sanitary Authority have decided to again take the matter of electric lighting into consideration.

UP-THAMES PLEASURE LAUNCH.—A new pleasure steamer, intended for service between Richmond and Hampton Court, was, we regret to learn, launched from the yard of the Thames Electric and Steam Launch Company, at Eel Pie Island, Twickenham, on Saturday last. The new boat is designed by Mr. W. S. Sargeant, and affords accommodation for 300 passengers. The vessel is propelled by a single screw, having three blades of Bull's metal supplied by the Phosphor Bronze Company, and is fitted throughout for the electric light. So large a vessel cannot fail to prove an intolerable nuisance on this part of the Thames.

WORCESTER.—The Watch Committee, at its meeting on Friday last, received a report from the sub-committee on electric lighting, which stated that a large number of applications had been received for the electric light, and those granted included several churches. It was stated also that the Dean was anxious to instal the light in the cathedral. The committee recommend the Corporation to vote a sum of £1,000 as working capital to pay the cost of such extensions as the committee decided were necessary.

WREXHAM.—The Board of Trade have intimated that they are prepared to defer the consideration of the question of revoking the Provisional Order of the Wrexham and District Electricity Supply Company (Limited) for twelve months.

COMPANIES' MEETINGS AND REPORTS.

Electric Construction Company (Limited).

The following report of the Directors of this Company, for the year ended June 30th last, is to be presented to the shareholders at the first annual general meeting, to be held on Thursday next, the 13th inst., at the Cannon-street Hotel, London, E.C., at 2:30 o'clock :—

During the year shares and debentures of other companies have been sold at a profit of £15,764. 10s. The profit and loss account shows a gross profit of £55,362. 2s. 9d., and, after deducting all general charges, interest on debentures and borrowed capital, and cost of maintaining buildings, plant, and patents, and allowing the sum of £3,000 for depreciation, there remains £18,467. 13s. 8d., which the Directors recommend should be appropriated as follows :—

£12,500	0	0	in reducing the amount at debit of "shares and debentures of other companies' account."
1,888	2	1	in writing off the reconstruction and preliminary expenses, and
1,819	6	0	in paying the dividend on the Preference shares at the rate of 7 per cent. per annum for the year, leaving
2,260	5	7	to be carried forward to next account.
£18,467	13	8	

The working expenses compare favourably with those of the old Company, and further economies will be carried out as opportunity offers. The liabilities of the Company have been reduced during the year by £48,236. The business has, to some extent, been interrupted by the reconstruction of the Company and the reorganisation at the Bushbury Works, and under the circumstances the results for the year may be considered satisfactory. The Directors have confidence in the ability and loyalty of the staff, and, with the excellent factories and capable artisans of the Company, improved results to the shareholders may reasonably be expected.

Several important electrical contracts have been carried out during the year. The working of the Liverpool Overhead Railway was handed over to that Company to their entire satisfaction on January 1st last. The electrical tramway of the South Staffordshire Tramways Company continues to be worked by this Company, and the cost of working for a period now exceeding eighteen months demonstrates the great superiority and economy of electricity as compared with other modes of traction. Numerous orders for electric lighting and other applications of electricity are being executed.

Sir Daniel Cooper, Bart., and the Right Hon. David Plunket are the retiring Directors. Sir Daniel Cooper offers himself for re-election, but Mr. Plunket, in consequence of other engagements, retires, and the Directors recommend that the vacancy be not at present filled up. Messrs. James Meston and Co., who were appointed to audit the accounts issued with this report, offer themselves for election as auditors for the ensuing year.

The Collier Audible Telephone Syndicate (Limited).

The statutory meetings of the creditors and shareholders of this Company were held last week at the offices of Mr. Winearls, Assistant Official Receiver, Carey-street, London, W.C.

The proofs having been dealt with, the Chairman said the usual statement of the Company's affairs had only recently been filed, and the Official Receiver's observations upon the case would have to be sent out to the creditors and shareholders at a later date. The syndicate was registered in April, 1891, to acquire and develop certain inventions of Mr. A. T. Collier for improved telephonic receivers and transmitters, and to carry on the business of a telephone and electrical manufacturing and supply company. The nominal capital of this syndicate was £9,000, the promoters being the London and Colonial Finance Corporation (Limited). When the Directors went to allotment about £2,400 had been subscribed, and immediately afterwards the syndicate commenced business, which appeared to have consisted exclusively of experimental work in connection with Mr. Collier's inventions. The working capital was put at £3,000, and, upon its being exhausted, loans were raised by means of debentures, and otherwise, to carry on the business. In 1892 the Collier-Marr Telephone and Electrical Manufacturing Company (Limited) was formed to take over the assets of the syndicate, the consideration being £50,000, payable in cash and shares. The syndicate in October, 1892, for the purpose of carrying out the sale to the Company, went in voluntary liquidation ; but eventually a compulsory winding-up order was made upon a petition lodged by a creditor. The unsecured claims, which in 1892 amounted to £1,525, had been reduced to £606 at the date of the winding-up order. It was alleged that some of the creditors had been paid in preference to the remainder, but this was a matter which would be dealt with by the liquidator later.

A section of the meeting urged the appointment of Mr. B. Davies, of Messrs. Isaac Coop, Davies and Co., chartered accountants, Coleman-street, E.C., for the post of liquidator, but the majority voted in favour of leaving the case in the hands of the Official Receiver to be wound up in the usual manner, and the Chairman finally intimated that the question would be referred to the Court for decision.

CITY NOTES.

AFRICAN GOLD RECOVERY COMPANY (LIMITED).—It is stated that the actions brought by this Company which have been for some time pending in the Transvaal Courts, in which the validity of its patents for treating mine tailings, &c., have been contested, resulted in a victory for the Company, who have received payment of royalty from the various defendants.

BABCOCK AND WILCOX (LIMITED).—The Directors of this Company recommend the payment of dividends for the half-year ended June 30th last at the rate of 15 per cent. on the Ordinary shares, and 6 per cent. on the Preference.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended September 2nd were £794, as against £747 in the corresponding period of 1893, being an increase of £47. The total receipts for the half-year amount to £7,736, as against £7,394 for the corresponding period of 1893, an increase of £342.

COMMERCIAL CABLE COMPANY.—This Company announce the payment of a quarterly dividend of 1¾ per cent. on the outstanding stock of the Company, payable on October 1st. The transfer books are closed from September 20th to the morning of October 2nd.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of August are £2,800, as compared with £2,851 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—This Company's estimated traffic receipts for the month of August, 1894, amounted to £1,583, as against £1,670 in the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of August amounted to £60,279, as against £51,991 in the corresponding period last year, being an increase of £8,288.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of August amounted to £44,638, and to £41,791 in the corresponding period of 1893, being an increase of £2,847.

ELECTRIC CONSTRUCTION COMPANY.—It will be seen from the report of the Directors (which appears elsewhere) that the wise course has been taken of writing off out of the profits of the year from the debit of shares and debentures in other companies the considerable sum of £12,500. Notwithstanding this, the year's profits allow the full dividend on the Preference shares, of £3,000, being written off to depreciation, and of the carrying forward of £2,260.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for the month of August, 1894, amount to £26,800, and from January 1st to August 31, 1894, £182,200. In the corresponding months of 1892 and 1893 the amounts were £175,600 and £180,000 respectively.

LEICESTER.—The Corporation invite tenders for £135,000 in Three per Cent. stock, to be redeemed at par in 1944, unless previously cancelled. The proceeds of this loan will be devoted to the construction of waterworks and electric lighting works, and is secured on the Borough fund and rates and revenues of the Corporation, including water, gas, and electric lighting revenues. The list closes to-morrow (Saturday).

MERSEY RAILWAY COMPANY.—At the half-yearly meeting of this Company, held last week, Mr. A. B. Kitching, who presided, stated that the Directors had caused inquiries to be made as to the practicability of working the railway by electricity, and so far as these inquiries had gone the information they had received was encouraging. They were awaiting further information and details before coming to a decision on the subject.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended August 31st (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,542.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts for this Company for the two weeks ending August 31st were £1,702, as compared with £1,737 for the corresponding period of last year.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 852.—Vol. XXXIII. FRIDAY, SEPTEMBER 14, 1894. PRICE FOURPENCE Annual Subscription (U.K.), 18/.

NOTES.

Compared with the ordinary run of accounts those published by electric lighting concerns under the auspices of the Board of Trade are models of clearness and explicitness, although no more than other human documents do they tell the truth, the whole truth, and nothing but the truth. However, taking them for what they are, these Board of Trade accounts tell something even to the uninitiated, and much to those who delight in analyses and "odorous comparisons." Clear and explicit as these accounts usually are, however, we do not remember to have seen any quite equal to the just-issued 1894 electric lighting accounts of the Glasgow Corporation, the main figures of which we gave some weeks ago.

The second year of the Glasgow municipal station shows, indeed, a deficit like the first; but it is a considerably diminished one (£607 as against £1,773), and likely, by the look of the accounts, to be converted next year into a profit; that is to say, if the lowering of the price of the Board of Trade unit from 7d. to 6d. brings about the anticipated growth in the consumption of current. Although the Glasgow station does not, more than any other municipal venture of the kind, as yet show any symptoms of the overwhelming superiority of municipal management regarded purely from the £ s. d. point of view, now almost out-of-date, it may be of interest to note that the generating expenses at Glasgow are a little over 2d., as against 2½d. with the Kensington and Knightsbridge Company, which is worked on the same system, and has a capital expenditure and output of the same order of magnitude. This is a good figure, but is, no doubt, quite accounted for by the difference in the price of fuel in Glasgow, and in Kensington, and by the fact that in Glasgow nearly 30 per cent. of the total units are sold in connection with the public lighting, with its steady load and long and definite hours. When we come to total cost per unit sold, including the sums set aside for depreciation, the Glasgow and Kensington figures are respectively 4⅜d. and 4¼d. We observe that the units unaccounted for still amount to 16 per cent. of the total number generated, the figure for the previous year having been no less than 26 per cent. This is, probably, as much a matter of meters as of mains.

We are glad to receive support, though in guarded language, from Dr. Fleming, in the sine curve controversy, and await with interest the result of his experiments. Meanwhile, it seems that the whole American nation has not risen up against us, but that, if left to themselves, the Americans will settle the matter for themselves without our assistance. Mr. Shand, whose name is well known in connection with the old Thomson-Houston Company, though he concludes the letter which we print this week with a verdict of not proven, amply confirms our views in the rest of his letter. To one short paragraph we would particularly draw attention, with the view of simplifying the debate: "Of course, in particular transmissions, when the use of alternators giving sine waves appears desirable, they will be met as special cases, and so treated."

We reprint in another column a brief description of the ingenious method adopted at Bangor (Me.) of working a small trolley line on the three-wire system. Mr. Carrol's experience at Bangor is of interest not only on account of the potentialities of the three-wire solution of the problem of the earth return, but because it shows that with a little care and thought the plan may be made quite workable even on a small scale. Necessity was the mother of invention in this instance, as in most others. A water power-house, situated 4½ miles from the nearest feeding point, the refusal of the "earth," even, with a river in obliging proximity, to act gratuitously as an electrical waste pipe, and the impossibility, in view of the relatively large capital outlay, of a copper return of the orthodox kind, all combined to make Bangor (Me.) famous as the first town, or ought we to say city, to adopt the three-wire system of electric traction.

Higher commendation of electric traction could hardly b given than is to be found in the remarks made by Sir William Forwood in the discussion at the Institution of Civil Engineers on the Liverpool Overhead Railway, and which we print in another column. This railway, of which he is Chairman, was commenced with the idea of using steam, but after he had visited America, and had seen what had been done there in electric traction, he felt sure that something better should be done and could be done in England; and not only had it been done, but in his opinion there was nothing in America comparable with the electric railway in Liverpool. Sir William Forwood is not known as an electrical expert, and it is not on such grounds that his opinion is valuable, but he is well known both in Liverpool and in Parliament as a shrewd and practical man. The control of the motors, the working of the signals, and the efficiency of the conductor are interesting to some minds; but Sir W. Forwood seizes the cost of locomotive expenses, the punctuality, and the reliability, as the points which are convincing to him of the success of the work.

Sir Douglas Fox described several practical details of construction of the line, and alluded to the important consideration of the number of stations. The perfect ideal, as he put it, would be to have one station the whole length of the line. That, he said, could not be quite accomplished. But in this matter of stations lies one of the great differences between railways and tramways. Nearly all tramcars and omnibuses in this country will pull up on being hailed, or when a passenger wishes to alight, and a similar concession is frequently made on the light railways of the Continent. This is no doubt a convenience to individuals, and as a large proportion of the passengers take advantage of this privilege twice on every journey, it appears that the balance of convenience to each person and inconvenience to many is thus adjusted. But the practice of stopping at definite points has much to commend it, especially in the case of electric traction, where, as a rule, each start entails a heavy discharge of current, and perhaps a loss by the use of resistances.

A tramway, in the ordinary sense of the word, has no stations, and, by dispensing not only with the buildings but with the attendants, the expenses are, of course, much less than with a railway. Electric railways will probably create a new type of service, especially where motor cars are used, for trains of moderate length can be run at very short intervals. A three-minute service has hitherto been the ideal, and where it is necessary to keep time and to maintain the same interval throughout the day, it is, perhaps, as short as is practicable. But when the bulk of the traffic is concentrated in a few hours of the morning and evening, it seems possible to circulate the trains faster during that time. Under certain circumstances an express service might be run, the alternate trains stopping at alternate stations. This would greatly reduce the time from terminus to terminus, and it might be worth while to arrange an automatic block system as proposed by Profs. Ayrton and Perry, whereby the trains could not possibly approach each other.

Means for "turning down" electric light seems to have as great a fascination for inventors as the "distribution" problem of 16 years ago. The *Birmingham Gazette* discusses at great length the "important invention" and "discovery" of a Mr. T. B. Sharp, "a well-known inventor," who "has solved the mystery after devoting much serious thought to the subject, and making innumerable experiments." His attention was first called to this long-felt want by observing that a stocking had been tied round a lamp for the purpose of producing a dim night-light in a hotel bedroom. "His first idea was to place a make-and-break arrangement in the circuit in which the lamp is," and to this end he provides a commutator driven "by clock-work or any other means . . . . which cuts off the electricity instead of wasting it, and saves power very nearly in proportion to the time the current is broken, and the amount of light given is much in the same proportion." Mr. Sharp has, so far, only arrived at half the invention with which the Patent Office was deluged in 1878. In the months of October and November alone, no less than ten patents were granted for cutting the current off from one lamp, and sending it, during the interval, through another by means of revolving commutators.

It is interesting to compare the economy of this system with that of an ordinary resistance, and to consider the "worth whileness of the economy." Suppose a 16-c.p. lamp taking 0·64 ampere at 100 volts, that is, 4 watts per candle, is to be reduced to 1-c.p., the average current, whether continuous or intermittent, will be about 0·4 ampere. The resistance of the lamp will increase from 156 ohms to 170. If the current is reduced in the ordinary way, by inserting a resistance, 80 ohms will be required, and 12·8 watts will be lost in heating it, the lamp itself will take 27·2 watts. The consumption in the lamp will be 27·2 watts per candle, and the total consumption will be 40 watts per candle. Now, with the revolving commutator the average current will be as before, 0·4 ampere; but this is effected by cutting off the current for a certain time. The total consumption will be 40 watts per candle, as before, and the cost of the commutator would, we imagine, be more than that of a resistance. It is true that the cost per candle is tenfold greater, but the cost per lamp is reduced to about two-thirds. But, after all, a resistance would affect precisely the same saving, and would cost less.

Mr. Sharp saw some objections to the revolving wheel; it would of course consume far more energy than it would save, "so he turned his attention to the discovery of still another method," and not only by a powerful effort of thought has he imagined the principle of connecting lamps in series, but he has, possibly after "innumerable experiments," put his discovery into practice. He, in fact, takes advantage of the fact that a lamp is a cheap resistance, which will, indeed, under these circumstances, pay for itself—say, 1s. in 96 hours—taking as before the consumption per lamp and not per candle-power. The general result is that a 16-c.p. lamp tied up in a stocking, taking 64 watts at 6d. per unit, costs a trifle over 3d. for 8 hours, and if reduced to one candle by means of any of these brilliant inventions it will cost 2d. We have taken our data from tests of an average Edison-Swan lamp; with modern efficient lamps at 3 watts per candle the saving would be less. After all, we believe that excellent night-lights can be bought for 5d. per dozen. It is not so much about Mr. Sharp's inventions that we have gone so fully into these figures, but on account of the general fallacy of the economy of "turning down" lamps. The convenience of this practice is another matter, and between the use of a stocking and of complicated switches there is room for many inventions.

Protests are very properly being made in the daily Press about the practice of throwing advertisements by means of an electric lantern on the Nelson Column and the walls of the National Gallery. We have on several occasions, when in the neighbourhood of Trafalgar-square, seen a very disagreeable flicker, and some shadows resembling letters, but could not decipher any words. Business is business, but we feel sure that a large majority of our readers agree with us that this is not only a desecration of public monuments and buildings, but a prostitution of electric lighting.

Correspondence.—We are obliged to hold over some of our correspondence until next week.

Cable Interruption: Date of Interruption.
Zanzibar-Mombasa .... September 4th.

Edison Bamboo Filament Patent.—The ordinary legal life of this patent comes to an end on the 16th inst.

Mountain Electric Railways.—It is proposed to convert the Arth-Rigi Mountain Railway into an electric line, on the Thomson-Houston system.

Electricity in Mining.—The authorities of the School of Mines at Ballarat, Victoria, are about to establish a class in electricity, as applied to mining.

Inter-urban Telephony in Chili.—Negotiations are in hand with reference to the establishment of a telephone line between Valparaiso and Santiago, a distance of some 30 or 40 miles.

University College, London.—In the department of applied science, lectures and practical work in engineering and chemical laboratories commence on October 2nd. Prospectuses can be obtained at the College, Gower-street, London, W.C.

The Indo-Chinese Land Line.—*The Times* correspondent at Tientsin states that Mr. N. R. O'Conor, C.B., the British Minister, and the Viceroy have signed the convention by which the Chinese telegraphs are to be connected with those of Burma and India.

Pacific Cable.—Advices received by the Ottawa Department of Trade and Commerce state that H.M. ship "Champion" left Honolulu on August 27th for Neckar Island, to make soundings in the vicinity and report upon the adaptability of the island as a cable station.

Inter-urban Telephonic Communication in Italy.—It is stated that the Italian Minister of Posts and Telegraphs has decided upon the establishment of telephonic communication between Rome, Genoa, and Turin; Rome and Naples; Rome, Florence, and Milan; Rome and Venice; Turin and Milan; Turin and Genoa; Genoa and Milan; and Milan and Venice.

Car Lighting.—One of the electric cars of the North Hudson County Railroad, of New Jersey, has been experimentally equipped with a small auxiliary storage battery, which is charged from the main line, and is automatically switched into connection with the car lamps whenever the main current is interrupted—as by detaching the trolley from the wire—but is disconnected from the lamps when the main current is restored.

Lightning.—A labourer of Norton, near Evesham, was putting a sheet over a rick last week when a thunderstorm suddenly broke over the district, and he was struck by lightning and instantly killed. Nearly all his clothing was stripped from his body, and his boots were also torn from his feet.——Two of a number of tourists who were on the summit of Mount Pilatus watching the sunrise, a day or two ago, were overtaken by a thunderstorm and killed.

Combined Electric Traction and Lighting in Germany.—It is stated that the *Allgemeine Electricitäts Gesellschaft*, of Berlin, has secured the contract for the construction of the electric tramway at Königsberg, between the Pillau railway station and the suburb of Sackheim. The overhead conductor system is to be adopted, the line being about four miles long. The necessary electrical energy will be furnished by the municipal central station, which, it will be remembered, is on the five-wire system.

An Electric Weed Killer.—The Illinois Central Railroad is said to be experimenting with an electrical apparatus for killing grass and weeds. A car carries a dynamo-plant and a sort of brush, consisting of a fringe of copper wires, depending from its front end, which is made long enough to cover the width of the track and extend to the end of the ties. A pressure of 10,000 volts, produced by a step-up converter, is found to be sufficient to do the work effectively. Steam and brine have both been tried for the purpose, but with less satisfactory results than those which have attended the use of electricity.

The Telegraph in India.—Western innovations thrown into the midst of Eastern antiquities have sometimes to undergo curious modifications. Thus, side by side with the announcement that during the past financial year 8,000 miles of wire were added to the Indian telegraph system comes the statement that at Delhi, during the Mohurrum procession, the *tazias* having been made of unusual height, the telegraph wires were pulled down, not by the people, but by the authorities, so that the lofty structures might have room to pass. It is to be hoped this obliging disposition will not spread home, or the alleged loss on the telegraph service will loom still larger.

Electric Heating by Induced Currents.—In a recent issue of the *Zeitschrift für Elektrotechnik und Electrochemie* the following method of heating by induced currents is described. A vessel of suitable heat-resisting, and preferably non-conducting, material is constructed with a deep indentation in the bottom. Into this indentation is inserted the single primary coil of a coreless transformer. Within the vessel is a ring of lead or of carbon, which becomes heated by the induced currents flowing in it, when a suitable current is passed through the primary coil. If the vessel be made of metal it will itself act as a secondary conductor, and no additional ring of lead or carbon will be needed.

The People's Palace.—We have received a copy of the calendar of evening classes for the session 1894-95, which is issued by the governors of the People's Palace. The subjects taught at these evening classes cover almost every variety of technological instruction. In the spring of the present year the Drapers' Company, who have from the first heartily supported the People's Palace education scheme, voted a sum of £5,000 for the erection and equipment of separate workshops for the engineering department, which have now been completed, and are available for use for the session 1894-5. The course for the B.Sc. degree of the London University is offered. The evening classes are under the management of Mr. J. L. Hatton, M.A. The session commences on Monday, the 24th inst.

Charterhouse Science and Art Schools and Literary Institute.—The winter session of this institution will commence on Saturday, 29th inst. During the late session upwards of 1,100 students, mostly elementary teachers, availed themselves of the privileges afforded by this institution, and of this number nearly 950 presented themselves for examination and were successful in obtaining a large number of certificates awarded by the Science and Art Department of South Kensington. Instruction of a practical character is given in most of the sciences at a very nominal fee. Artisans who do not desire to be prepared for the examinations will this year be received and taught in accordance with the scheme issued by the London County Council. Full particulars of the classes may be obtained from C. Smith, organising secretary.

An Interesting Electric Railway.—An electric railway, for both passenger and freight traffic, is, says the *Engineering Magazine*, now in successful operation between the towns of Wilmerding and McKeesport, in Western Pennsylvania. The line is about four miles in length, and passes over a mountain 1,200ft. high, encountering some grades as steep as 12 per cent., with many sharp curves. Each car is equipped with two 30-H.P. motors. A conveniently-situated coal mine made it possible to locate the power house and car barn midway on the line, on a plateau at the top of the mountain, and a picnic ground has also been established nearby, which is expected to become a place of pleasure resort for the citizens of both towns, and thereby add largely to the revenues of the road. The water used in the boilers is pumped from the foot of the mountain by an electric motor.

The Aim of Electro-Chemical Investigations.—Under this F. Oettel, in a recent number of the *Zeitschrift für Elektrotechnik und Electrochemie*, urges that a new era will commence for electro-chemistry when electro-chemical reactions are studied with the aid of the amperemeter and the balance, as a new epoch began for chemistry with the quantitative examination of chemical phenomena. In studying electro-chemical reactions the current should be measured, and from this the theoretical result of the operation should be calculated according to Faraday's law; if, then, by weighing or titration this result is reached, it may be concluded that no secondary reactions have occurred. But if there be a difference beyond the range of experimental error, and this difference is found to recur on repeating the experiment, a further examination must be made into the nature, conditions, and extent of the by-reaction.

Electrical Resistance of Aqueous Solutions and Pressure.—In the *Wiener Berichte* for May will be found the results of researches by Bruno Piesch on the effect of pressure on the electrical resistance of solutions. The method of measurement was such that the resistance and the polarisation could be determined simultaneously. Pressures up to 600 atmospheres were produced by a Cailletet apparatus. The measurements gave the following results:—Change of pressure produces a change of resistance, which decreased in all cases with increase in the pressure. As the pressure increased the decreases of resistance were less. Polarisation also showed a change of value with higher pressure. These, however, are for the most part small. An increase of polarisation with the pressure was in general observed.

Electricity Applied to Mining.—A new colliery is being opened out on the Park Hall estate, near Eckington. About 1,000 acres of the High Hazle seam has been leased to an American gentleman by Mr. Chandos Pole, and operations are now proceeding under the management of Mr. Mylles Hardwick, mining engineer. The colliery is situated in the valley between Spinkhill and Barlbro'. A footrail is being driven into the hillside, and the seam of coal found is 4ft. in thickness. It is intended to work the colliery entirely by electricity. It is decided to put down high-pressure boilers, high-speed engines, and high-pressure dynamos. The under-cutting of the coal will be entirely done by "Jeffrey" electric coal-cutting machinery of the latest type. The colliery will be opened out on the pillar and stall system. The ventilating fan is to be driven by an electric motor. All the surface and underground workings will be lighted electrically.

Lighting Protection for Ships in Dry Dock.—Writing to Rear-Admiral J. A. Fisher, C.B., on the death by lightning of two men who had sought shelter under a vessel in the Norfolk, Va., dry dock during a thunderstorm, a disaster which was recorded some weeks ago in these columns, Lord Kelvin says:—"With reference to the recent report of a lightning discharge in Norfolk Dockyard, U.S.A., by which two men were killed, it is proved by that accident that to secure against danger to men working under a ship in dry dock there ought to be a thorough metallic connection, by wire rope or otherwise, between several points of the ship's iron, such as bollards, ring-bolts, &c., and iron pipes leading to the water outside the dry docks. Similar precautions ought to be taken in respect to the frames of ships on the stocks in the course of building, although we have, so far as I know, never heard of an accident from lightning happening to men at work in the building of ships. An iron ship simply resting on wooden blocks, and without any connection by metal with the water of docks, or river, or sea in the neighbourhood, is certainly dangerous to persons standing on the ground and touching any part of the iron hull during a thunderstorm."

Lightning in the United States.—According to a "Circular of Information," published by the United States Weather Bureau, 209 persons lost their lives in the United States by lightning during 1893, the total for the four years 1890-93 being 784, or an average of 196 per annum. All this loss of life took place practically in the five months April-September, the maximum death rate occurring in June and July. In the eight years ending 1892, for the most part west of the Rocky Mountains, there occurred in the United States 3,516 fires, doing damage to the amount of 2½ millions sterling. One interesting point which appears to be shown by statistical studies of lightning stroke is the decreased liability to accident in thickly-settled communities. It may be said in general that the risk in the country is five times greater than in the city. For ordinary dwelling houses, not unduly exposed in city blocks, lightning rods are hardly necessary, a very considerable protection being afforded by the tin roofing, numerous cornices, gutters, &c. The geological, as well as the topographical, conditions may have some influence upon the frequency of lightning stroke. With regard to trees, the oak is more frequently, and the beech less frequently, struck.

Graphics.—Mr. Henry Harrison Suplee, who is in charge of the mechanical engineering section of the *Engineering Magazine*, continues his campaign in praise of graphic methods. It is not uncommon, says Mr. Suplee, in the current issue of the magazine, "to hear men say that graphical diagrams will do very well for approximate results; but that the superior accuracy of calculations gives them marked superiority. It is doubtless true that results can be obtained by analytical methods to a far greater degree of refinement than is possible by the use of scale and dividers; but the sense of accuracy which is pleased with results carried out to the sixth decimal place is sometimes marred by the discovery that some important element in the calculation has been omitted, or, as is often the case, that it is impossible to use the results thus laboriously obtained to a greater degree of precision than, say, the second decimal place, and that the work which has been expended is unavailable. As a matter of fact the graphical processes will give results which are nearly always as precise as any of the subsequent uses which are to be made of the values thus obtained, and it is of little use, for instance, to determine dimensions which, when obtained, are to be laid out on a drawing, to a closer value than can be read from a scale or marked with a pencil, so that for such purposes the same system is equally reliable for the one or for the other. At the same time, it is possible to use graphical methods to investigate subjects which are only solvable analytically by most tedious labour and that, too, by those who have kept themselves expert in this branch of work by close study and constant practice. The true end of mechanical engineering is the production of the completed and operative machine, and this itself is a drawing, executed in steel and iron, and the symbols which are but as a means to this end need never be more precise than their final outcome in any case."

Velvo-Carbon.—The mania for new primary batteries has almost died out. A year or two ago there were a number of attempts at making "dry cells," a misleading name for a rather untrustworthy battery. The old idea of a primary battery consisted of three features. A secret depolariser, generally some form of chromic acid, a promise of a utilisable zinc salt from the spent solution, and a carbon plate. The two first requisites gave wide opportunity for ingenuity and lies, but nobody troubled about the carbon plates. There is no mystery about the last new battery, it appears to be a straightforward invention, and the new feature is the carbon. It consists of Lacombe arc light carbon rods 9 mm. diameter, one foot long, with velveteen cemented upon them, afterwards carbonised at a high temperature. For some purposes a deep-pile corduroy is used. The idea is to give a very large surface. A new method of electrically connecting carbon electrodes consists in the use of a silver wire, or strip wedged into a recess in the carbon. As at present applied to carbons for use entirely under the surface of simple dilute sulphuric acid, the carbons are of arc light rods as made for coring, but uncored. In the core hole at the end is wedged a length of 2in. of 28 gauge silver wire, by means of a celluloid wire wedge. If the connected portion of the carbon is to be above the level of the liquid the joint is protected by ozokerit wax. For use in depolarising solutions a platinum wire is used in place of the silver. The makers have chosen a rather severe kind of work for showing the capabilities of such a battery, and have fitted an electric launch 35ft. in length, 6ft. 6in. beam, 1ft. 4in. draught, with a Newton motor, weight 6cwt. This motor, when tested with 20 volts 60 amperes, ran at 500 revolutions per minute. A battery of 48 cells, of a total weight when charged of 14cwt., was arranged in two sets of 24 cells each. The water, or spent solution, is dealt with by an ebonite pump fixed permanently in the motor chamber, which communicates with the cells by lead pipes, and flexible rubber pipes. A charge of dilute sulphuric acid is said to run the launch "all day at full speed." The acid is tapped into the cells from a flexible lead tube, one end of which is inserted in the carboy on the bank. The whole of the cells may be charged or discharged in ten minutes. Half-an-hour is said to be sufficient time to replace a set of zinc plates. The amount of zinc used is said to be 6½lb. per supply unit, with 12lb. of acid. The former cost 5d. per pound, the latter ½d. per pound. Another experiment gave 5lb. of zinc, and 18lb. of acid per unit, making the costs of materials about 3s. per unit. It is claimed that for lighting purposes the solution is so weak that local action is negligible.

THE COST OF GLOW LAMP LIGHTING.*

It may not be inappropriate at this moment to call the attention of users of incandescent lamps to the fact that price is not the only factor to be considered in connection with the choice of a glow lamp. Consideration should also be given to the rate at which the candle-power decays when constant pressure is kept on the terminals of the lamp, as well as to the initial efficiency, and the *useful* life of the lamp. The useful life of the lamp, so far as most consumers are concerned, must be considered to be limited to that period of the total lamp life in which its candle-power is not diminished by more than 30 to 40 per cent. of its original candle-power, although this is not by any means a definite limit to the utility of the lamp. The user has to determine what is the total cost to him, during that useful life, of the energy supplied to the lamp, and what is the total candle-power hours given by the lamp. Suppose, for example, that the lamp is a 100-volt 16-c.p. lamp, and that it takes originally 50 watts to bring it to this candle-power, when on a 100-volt circuit. Then let us suppose, in the course of 600 hours' burning, that it is reduced to 8 c.p., and that it then takes 40 watts at the same pressure. If the rate of decay is tolerably uniform, the total energy taken by the lamp in watt-hours is the product of $45 = \frac{1}{2}\ (50 + 40)$, and 600, or 27,000 watt-hours; which is 27 British Board of Trade units (frequently written B.T.U.). The average candle-power hours given by the lamp is $\frac{1}{2}\ (16 + 8) = 12$, which multiplied by 600 gives 7,200 candle-power hours. If the Board of Trade unit of electric energy costs 6d., then the total cost of the energy taken up is 13s. 6d., for which the consumer gets 7,200 candle-hours of light at a mean candle-power of 12. If the lamp originally cost 1s. 6d., the total cost of the 7,200 candle-hours, including lamp, is 15s., or the consumer gets 40 candle-hours for a penny, given at a mean candle-power of 12. In other words, he is paying 0·3 of a penny per hour for his lamp and light. A penny includes, therefore, the cost of lamp and power for about $3\frac{1}{3}$ hours. Suppose, however, the user is offered a lamp at the price of 1s., but that extended experience shows that a 16-c.p. lamp of this kind falls to 8 candle-power in 300 hours' use. It is clear that this last lamp, if it takes the same power at each candle-power as the other, will transform in this time $45 \times 300 = 13{,}500$ watt-hours, or $13\frac{1}{2}$ Board of Trade units, and the total cost of lamp at 1s. and power at 6d. per unit to the user will be 7s. 9d. For this he gets $12 \times 300 = 3{,}600$ candle-hours, or 39 candle-hours for a penny. Hence, the cheaper lamp has not really much benefited him.

Therefore, the question which is so commonly asked, viz., Is electric light cheaper or dearer than gas? cannot be answered by a simple "Yes" or "No." The factors which decide the relative cost, so far as the electric glow lamp is concerned, are as follows:—1st. The price paid per Board of Trade unit of electric energy. 2nd. The price of the lamp. 3rd. The average useful life of the lamp. This last will depend not only upon the lamp itself, but also upon the constancy of the electric pressure of the supply. 4th. The manner in which the "wiring" of the house or building has been done; a factor which greatly determines the degree to which the consumer can effect economy by not using more lamps than is actually necessary. 5th. The intelligence shown in placing the lamps so as to make each do the utmost illuminating duty, and the care with which the control is effected by switching off lamps not actually needed. We may add also a 6th. The employment of a by-no-means negligible precaution in securing the best results—the keeping of the outside of the lamps clean and free from dust and dirt by having them well washed at intervals. A dusty lamp gives much less light than a clean one.

To assist the reader in making certain essential comparisons, a table is given below which shows the total cost in power and lamp renewals for working for 200 hours a 16-c.p. 100-volt glow lamp taking on an average 50 watts. The costs are given for various prices of the Board of Trade unit from 3d. to 8d., and for lamps costing 1s. and 1s. 6d., and for useful lives of from 200 to 1,000 hours. Let it be borne in mind that the "useful life" of a lamp is not a sharply marked period, but is the approximate average time during which its candle-power has not deteriorated by more than say 40 per cent. of its original value.

Table *showing the cost of 200 hours' use of a 100-volt 16-c.p. Glow Lamp, including the proportionate cost of Lamp Renewals and cost of Power. The Lamp is assumed to take on an average 50 watts, and to cost either 1s. or 1s. 6d.*

Cost of Energy. Board of Trade Unit.	3d.		4d.		5d.		6d.		7d.		8d.	
Price of Lamp.	1/-	1/6	1/-	1/6	1/-	1/6	1/-	1/6	1/-	1/6	1/-	1/6
Useful Life of Lamp in hours.	Cost of 200 hours' use of Lamp.											
200 hours.	3/6	4/-	4/4	4/10	5/2	5/8	6/-	6/6	6/10	7/4	7/8	8/2
400 "	3/-	3/3	3/10	4/1	4/8	4/11	5/6	5/9	6/4	6/7	7/2	7/5
600 "	2/10	3/-	3/8	3/10	4/6	4/8	5/4	5/6	6/2	6/4	7/-	7/4
800 "	2/9	2/10	3/7	3/8	4/5	4/6	5/3	5/4	6/1	6/2	6/11	7/-
1,000 "	2/8	2/9	3/6	3/7	4/4	4/5	5/2	5/3	6/-	6/1	6/10	6/11

The foregoing table must be read as follows:—Suppose the user gets current at 6d. per unit, and buys lamps at 1s. 6d., and let the lamp he buys be assumed to have an average useful life of 800 hours. On looking along the column in line with 800 and under the heading 6d. and 1s. 6d., will be seen 5s. 4d. This is the cost of the 16-c.p. lamp for 200 hours of burning, including proportion of lamp cost and power. Hence, in this case the 800 hours' burning cost 21s. 4d. on the whole, and for this the user gets an average candle-power of about 13 candles for 800 hours, or $13 \times 800 = 10{,}400$ candle-hours. It is obvious that no hard and fast comparison with the cost of equivalent candle-hours given by gas light is possible, unless a careful statement is made of the manner in which the two lights are used.

One great advantage which electric illumination possesses, from a domestic and economical point of view, is the ease with which it can be turned off and on. A switch placed near the door enables a person leaving a room to turn out all the electric lights without calling for the smallest trouble in relighting them, which cannot be done in the case of gas. In effecting a comparison of cost, we have to take into consideration the time of wastage and non-useful combustion in the consumption of gas; and this, apart altogether from the immense superiority of the illuminant which fouls no air and destroys no decorations. Actual extended experience shows* that, with care and good management, electric energy at 8d. per unit can be made to give as much illumination by means of incandescent lamps as gas at 3s. 2d. per thousand cubic feet used with ordinary gas burners. At this rate, one Board of Trade unit of electric energy can be made to do the work of about 200 cubic feet of gas.

A very important factor which enters into the question of the cost of incandescent lighting is the care with which the arrangements of the electric light "wiring" have been carried out. The "wiring" may be done in such a way that the user can only turn on and off large groups of lamps at once. As far as possible each lamp should be on a separate switch, and be capable of being used and put out of use alone. Such independent wiring costs more per light than group lighting, but it enables the user to create the necessary illumination with a minimum of expenditure of electric energy.

The actual average annual consumption of electric energy by incandescent lamps placed in buildings of various classes differs very greatly. Taking the case of supply by meter, it is found that for a large class of private houses the average number of Board of Trade units taken per annum by an 8-c.p. lamp will

* From a forthcoming work on "Electric Lamps and Electric Lighting," by Dr. J. A. Fleming, to be published by *The Electrician* Printing and Publishing Company. All rights reserved.

Digitized by Google

not exceed 12 to 20. Indeed 20 is generally an outside limit. Lamps in clubs, hotels and restaurants show a very much larger average than 20, and may reach 30 to 40 B.T.U. per 8-c.p. lamp per annum, or occasionally even more. It may be mentioned that a 16-c.p. lamp would, under the same conditions, take twice, and a 32-c.p. three times the above amount. Since a 35-watt 8-c.p. lamp takes one B.T.U. of electric energy in 30 hours of continuous use, it follows that from 360 to 600 hours is the average total time during which a lamp in a private house is in use in the year. That is, from one hour to one hour and a half is the average daily time during which each lamp is alight in residential buildings. During the other 23 or 22½ hours of the day, however, the electric supply station has to keep in readiness, machinery or other apparatus capable of giving current for that lamp should the user require it. The *load factor* of a supply station is the ratio of the actual amount of Board of Trade units sold to the amount which could be sold if the demand were constant and equal to the maximum demand. It will be seen from the above figures that the load factor of an electric supply station, supplying a purely residential district, does not exceed 8 or 10 per cent. The load factors of various classes of buildings are very different. The load factor of private houses is seen from the above figures to be even below 8 per cent. The most profitable consumers, therefore, from the point of view of the suppliers of electric current, are not those who have most lamps, but those who use the lamps they have for the longest number of hours.

THE RISE OF CURRENT IN INDUCTIVE CIRCUITS.

BY ALEXANDER RUSSELL.

The following extension of some theorems connected with the rise of current in an inductive circuit to the rise of current in branched circuits is simple, and leads to some very interesting results. For example, on closing a main circuit which branches off into various inductive paths, we may get a reversal of current in some of the branched circuits, and on breaking the main circuit we may get a reversal of current in other of the branched circuits. For simplicity, the case of two circuits only has been considered in this Paper, as the extension of the algebraical laws given to any number of branches is obvious. The curves, showing the rise of current, were drawn from somewhat complicated mathematical equations, which have been omitted as unnecessary, seeing that a study of the graphical numerical examples will give a very good idea of what happens in the general case.

For convenience, the coil, which has a resistance of R ohms and a self-inductance of L henrys, is denoted by the coil (R, L). It is well-known that when a difference of potential, V, is established between the terminals of a resistance coil, the current in the coil, owing to the back E.M.F. of self-induction, does not instantaneously assume its value, but takes a certain finite time to rise to its steady value. If the coil be (R, L), the rate at which the current grows at the start is $\frac{V}{L}$ and then the rate at which it rises rapidly diminishes until it becomes zero and the current attains its steady value $\frac{V}{R}$. If it had attained this value instantaneously, more electricity would have circulated in the coil. Hence the effect of induction is to block out a certain number coulombs (Q) from the coil. There is also a certain number of joules ($\frac{1}{2}$ Q V) stored up in the coil in the form of electro-kinetic energy, which energy will manifest itself by a spark if the circuit be broken, or will cause a quantity, Q, of electricity to circulate in the coil if it be short-circuited. In the latter case the current subsides, rapidly at first and very slowly afterwards, to zero.

It can be shown that if A_1 be the steady value of the current n the coil (R, L) then

$$Q = A_1 \frac{L}{R};$$

$\frac{L}{R}$ is often called the time constant of the coil.

We shall now consider how the rise of current in a coil is affected by the presence of neighbouring closed circuits. Take the case of a coil (R, L) with a closed coil (S, N) near it (Fig. 1). Let M be the mutual inductance between the coils, and let V be the potential difference instantaneously established at the terminals of (R, L). The rise of current in (R,L) induces a current in (S, N) which attains a maximum value, and then dies away, becoming zero when the current in (R, L) attains its steady value. It is obvious that the rise of current in (R, L) will not be the same as when there was no closed circuit near it, as the induced current in (S, N) reacts on the current in (R, L); helping its rise when the current in (S, N) is increasing, and opposing its rise when the current in (S, N) is diminishing.

Hence the current in the coil (R, L) rises more rapidly at first and less rapidly later on than if mutual induction were absent (Fig. 2).

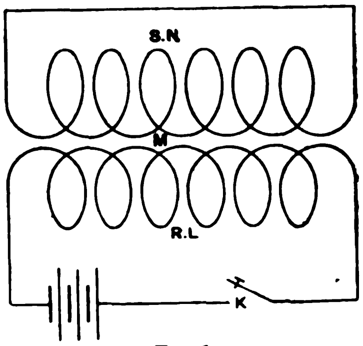

FIG. 1.

Figs. 2 and 3 show the rise of current in the two coils, when the values of the constants are R = S = 1 ohm, L = 0·5, N = 1, M = 0·6 henry, V = 3 volts.

The quantity of electricity that circulates in the coil (S, N) is equal to $A_1 \frac{M}{S}$ where A_1 equals $\frac{V}{R}$. In the case shown it equals 1·8 coulombs. Since the quantity induced in a coil depends upon the *final value* of the inducing current, it follows that the total quantity of electricity that circulates in the coil (R, L) due to the E.M.F. of mutual induction caused by the current in (S, N) is zero.

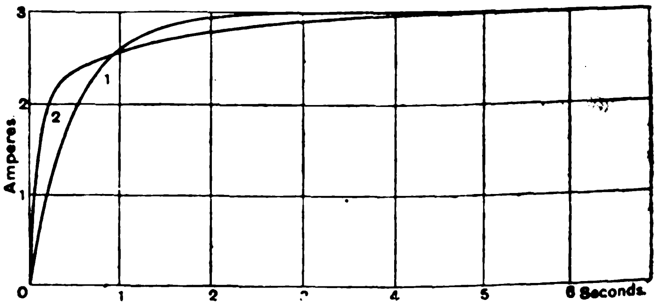

FIG. 2.—(1) Rise of Current, no Eddy Currents produced. (2) Rise of Current, affected by Eddy Currents.

Hence the amount of electricity blocked out of the coil (R, L) by induction is the same, whether the coil (S, N) be near it or away from it. The work done in raising the current to its steady value is the same in the two cases, and the electro-kinetic energy stored in the coil ($\frac{1}{2}$ Q V) is also the same. Therefore the heating effect on the coil (R, L) is less when there is a closed circuit near it. Again, suppose the coil (R, L) to be short circuited; the energy stored in the coil gives rise to currents in the two coils. Let H_1 and H_2 be the respective heating effects produced, then

$$\tfrac{1}{2} Q V = H_1 + H_2.$$

Thus H_1 is greatest when H_2 is zero; that is, when there is no mutual induction.

To get the curve showing the falling away of the current when the coil (R, L) is short circuited, we look at the curve (Fig. 2) upside down; the new line along which time, and above which amperes are measured, being the line 3T. The curve

Digitized by Google

(Fig. 3) being the same as before, the currents being merely in the reverse direction.

The case of the rise of current in two neighbouring inductive coils connected in parallel is important. Let (Fig. 4) (R, L) and (S, N) be the two coils, and suppose that when there is a difference of potential, V, between B and C, the steady current in the (R, L) branch is A_1 amperes, and the steady current in the (S, N) branch is A_2 amperes. Then, by what has gone before, the quantity of electricity blocked out of the (R, L) branch by self-induction is $A_1\frac{L}{R}$, and in addition to this there is a quantity $A_2\frac{M}{R}$ blocked out by mutual induction.

Hence if Q_1, Q_2 be the total quantities blocked out of the two branches by induction, then

$$Q_1 = A_1\frac{L}{R} + A_2\frac{M}{R} = A_1\left(\frac{L}{R} + \frac{M}{S}\right), \quad . \quad . \quad . \quad . \quad (1)$$

$$Q_2 = A_2\frac{N}{S} + A_1\frac{M}{S} = A_2\left(\frac{N}{S} + \frac{M}{R}\right). \quad . \quad . \quad . \quad . \quad (2)$$

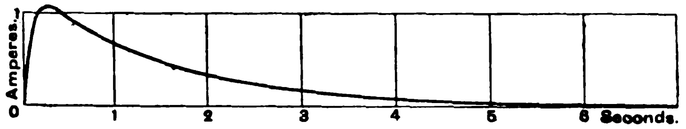

FIG. 3.—Rise of Current in a Closed Coil near an Inductive Circuit.

Now in the formulæ (1) and (2) M may be either positive or negative, depending on how the two coils are connected in parallel. When M is negative, it will sometimes happen that either Q_1 or Q_2 is negative. Of course, they cannot both be negative. Suppose Q_1 is negative, then, in this case, more electricity flows through the coil (R, L) than if there were no self and mutual induction. Hence the current in this branch must at first attain a value greater than its steady value. Again, since $\frac{M}{S}$ may be very large compared to $\frac{L}{R}$, the quantity blocked out of the (R, L) branch may be very large, so large, in fact, as to necessitate the current flowing in the reverse direction at the start in order that the requisite quantity be blocked out before the current attains its steady value.

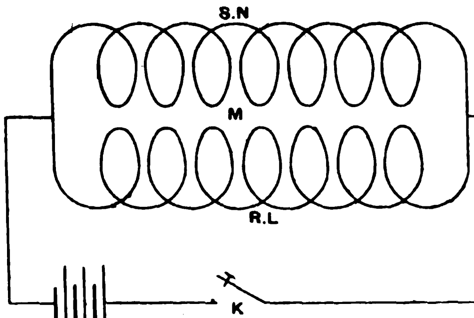

FIG. 4

The curves, Figs. 5 and 6, show the rise of current in the two arms when

$$R = S = 1 \text{ ohm}; \; L = 0{\cdot}5, \; N = 1 \text{ henry}; \; V = 3 \text{ volts}.$$

The curves (1) show the rise when M = 0. The curves (2) show the rise when M = +0·6 henry; and the curves (3) show the rise when M = −0·6 henry. The curve (2), Fig. 5, shows the rise of current in the coil when M = 0·6. The current at first rises more rapidly than if mutual induction were absent, and then less rapidly. The quantity of electricity blocked out, which is represented graphically by the area contained between the curve (2) and the lines 03T is, however, greater than if there were no mutual induction, the difference between the areas of the two loops formed by (1) and (2) being $A_1\frac{M}{S}$. The curve (3) (Fig. 5) shows the rise of current in this arm when M = −0·6.

In this case the current rises very rapidly, attaining a maximum value of nearly 3·3 amperes when the time is 0·5 seconds, and then gradually subsiding to its steady value of 3 amperes. The area included between (1) and (3) is as before $A_1\frac{M}{S}$.

Similar remarks apply to the curves shown in Fig. 6. The curve (2) in this figure is interesting, showing a reversal of current in the branch (1, 1) when M = +0·6, the current attaining its maximum negative value when the time is nearly 0·07 second.

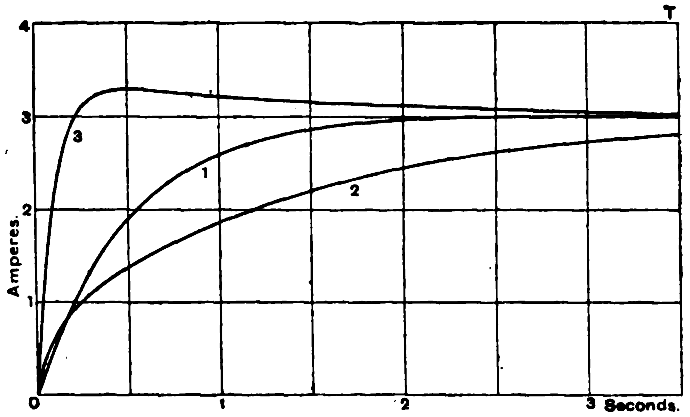

FIG. 5.—Rise of Current in One Arm of a Branched Circuit. (1) No Mutual Induction; (2), Mutual Induction helping Self-Induction; (3), Mutual Induction opposing Self-Induction.

Fig. 7 shows the rise of the resultant current in the two branches. At any moment the ordinate of the curve in Fig. 7 equals the sum of the ordinates of the corresponding curves in Figs. 5 and 6. The total quantity of electricity blocked out of the two coils in parallel is $Q_1 + Q_2$, which is equal to the area between 03T and the curve in Fig. 7, and the electro-kinetic energy stored in the two coils is $\frac{1}{2}(Q_1 + Q_2)$ V.

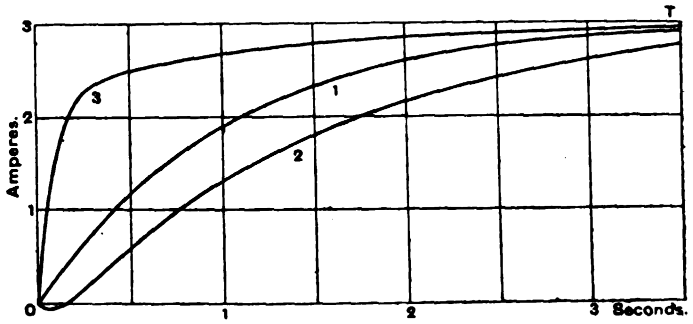

FIG. 6.—Rise of Current in other Arm. (Looked at upside down, and taking the line 3 T as the line along which time is measured, and above which Current is measured, these Curves show the fall of Current when the two Branches are Short Circuited.)

Substituting the values of Q_1 and Q_2 from (1) in this expression, we find that the electro-kinetic energy is equal to

$$\tfrac{1}{2} L A_1^2 + \tfrac{1}{2} N A_2^2 + M A_1 A_2,$$

and this may vary between wide limits depending on the value of M. M must lie in value between

$+\sqrt{LN}$ and $-\sqrt{LN}$. If M equals $-\sqrt{LN}$ and $\frac{R}{S}$ is equal to $\sqrt{\frac{L}{N}}$, the electro-kinetic energy would be zero, no electricity would be blocked out, and there would be an instantaneous rise and fall of current.

These effects are very well illustrated by connecting the two coils of an ordinary transformer in parallel, and then sending a direct current through them. With a small Lowrie Hall transformer, a tangent galvanometer was put in series with its high-tension circuit, then, on making the circuit, the needle swung 6 deg. to the left, and then took up a steady deflection of 15 deg. to the right. Hence in this case we had a reversal of current in the high tension arm. On breaking the circuit the needle swung 5 deg. farther to the right, and then settled down to zero. Again, when the connections of one of the parallel arms were reversed, on closing the circuit there was a

Digitized by Google

large deflection to the right, and on opening the circuit a still larger deflection to the left, showing that there was again a reversal of current in the high tension arm. A small compass needle with a few turns of wire round it can be used instead of a tangent galvanometer.

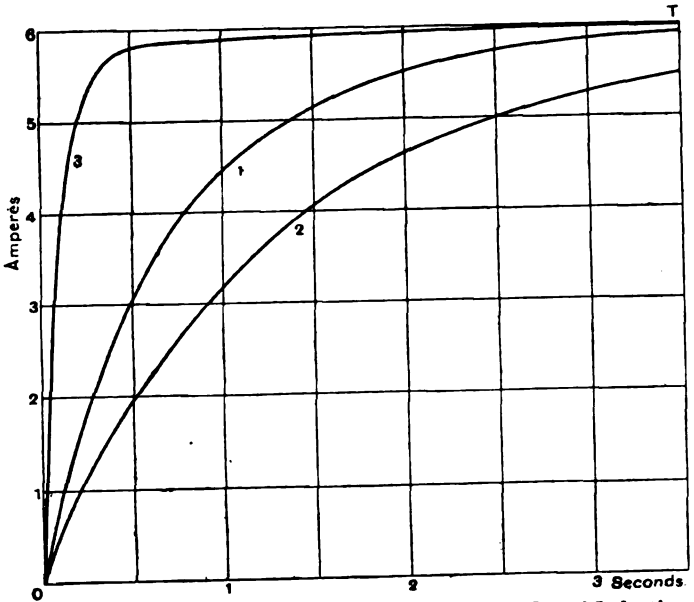

Fig. 7.—Rise of Current in Main Branch. (1), No Mutual Induction ; (2), Mutual Induction helping Self-Induction ; (3), Mutual Induction opposing Self-Induction.

It is easy to devise some very striking lecture-room experiments, showing how by increasing the resistance of one branch we can make the reversal of current vanish in that branch and take place in the other.

THE ILLUMINATING POWER OF PROJECTORS.*

BY F. NERZ.

The great projector exhibited by the Electricitäts-Actiengesellschaft (formerly Schuckert and Co.) at the Chicago Exhibition has been the source of many lucubrations in the technical press, some of which are not calculated to conduce to the better understanding of this subject. Prof. Silvanus Thompson, in *The Electrician* for September 29, 1893, gives vent to a criticism of the statement that this projector illuminates distant objects with an intensity of 190 million standard candle-power; and he comes to the conclusion that for this result a crater-surface of 17·6 sq. metres would be required, since it is known that an arc giving only a million candle-power requires about 0·093 sq. metre surface of crater. Prof. Thompson does not give us any information as to the conditions under which this is true. If the value is intended to mean the zone of greatest intensity, then Prof. Thompson takes the surface much too high. His figure works out at 11 c.p. per 1mm. square of crater surface; while for the 8-ampere lamp of commerce a mean spherical intensity (not maximum) of about 320 c.p. is attained, being about 20 c.p. per 1 sq. mm. A lamp for 60 amperes has a crater about 12mm. in diameter, and according to Thompson's figure should have 1,255 c.p. The actual maximum intensity measured by the author is more than ten times as great.

The glass parabolic mirrors now made by the Elektricitäts-Actiengesellschaft, receive the light of a horizontal lamp under an angle of incidence of about 120 deg., and therefore include the most powerful rays emitted by the crater of the positive carbon. The average intensity of the light falling on the mirror is about 80 per cent. of the maximum intensity of the arc. One must assume that Prof. Thompson in giving figures in support of his statements has taken this latter fact into consideration, and has not given the mean spherical intensity; but even for the latter case his figures are too small. One must also assume that he was talking only of lamps for large currents such as are used with projectors, and that his figures refer to these. Prof. Thompson's criticism rests on an erroneous idea as to the data for the determination of the illuminating power of projectors. It is obvious that he is considering the illuminating power of the intensity of the rays of the lamp falling on the reflector, whereas it is the illuminating power of the collected bundle of rays which must be dealt with. However, Mr. C. P. Steinmetz corrected this mistake in an article in *The Electrician* of October 27, 1893, and his conclusions are in agreement with those come to by the author in his Paper on the "Construction and Uses of Projectors,"* and there were little to add to this, had not the matter spread further and been discussed by Mr. C. Hering in the *Electrical World*, and M. E. Hospitalier in *L'Industrie Electrique*. Mr. Hering attempts to show that the general law of emission of light cannot be applied to projectors, because the light cannot be considered as starting from the projector, but rather from a theoretical source of light in a point, P, behind the mirror. To a question put of the largest manufacturers of projectors as to how the results of photometrical measurements on such apparatus are obtained, Mr. Hering has probably received no satisfactory answers. The answer of Messrs. Schuckert and Co. was as follows :—That they used a Weber photometer for their measurements of lamp and projector, the latter being not less than one kilometre distant. "The mean intensity of illumination of the rays falling on the mirror multiplied by the ratio of the squares of the diameter of mirror and crater must then give the intensity of illumination of the beam measured by the photometer, naturally allowing for atmospheric absorption." They refer him for further particulars to the author's pamphlet on projectors already published in *The Electrician*.

Thus the photometer is at least a kilometre from the projector. Now, Mr. Steinmetz gives the angle of the great Chicago projector at about 2deg., which would give an emission point 43 metres behind, thus giving 1,043 instead of 1,000 metres as the distance to the photometer. One may surely neglect this error, seeing that the photometer readings are not determinable to such limits of accuracy. The further remarks of Mr. Hering are quite unintelligible, in which he seeks to prove that the light coming from the projector does not follow the ordinary laws of light emission, and the author recommends Mr. Hering to read M. Blondel's articles in *L'Industrie Electrique* on the "Théorie Photométrique des Projecteurs," in which he shows that the measurements at Chicago are correct if the mirror be sufficiently nearly parabolic. This condition is quite justified, and the utmost efforts of the manufacturer should be directed to the production of a very close approximation to theoretical form. Tests of the Schuckert mirrors against the Mangin reflectors of Messrs. Sautter, Harlé and Co., have shown that the former glass mirrors are always superior in shape. There are several methods of testing the accuracy of the parabolic mirrors. The first, suitable only for comparisons, is that indicated above ; the two projectors are set up at the same distance of over a kilometre from the photometer, and provided with obscuring apparatus. The atmospheric conditions are then identical in the two cases. Tests so made by the military authorities in Austria of the Schuckert and the Sautter Harlé apparatus, showed, after a large number of observations, an advantage of 25 per cent. and upwards (averaging 36 per cent.) in favour of the former type.

A second method is the determination of the ratio of the spreading actually found to the theoretical amount. If d be the diameter of the crater, δ the angle at the apex of the shadow cone which is formed in the case of a horizontal lamp by the negative carbon, and ρ the radius of curvature of the parabolic reflector with the angle of incidence $\frac{\delta}{2}$, then the angle of spreading should theoretically be given by the equation

$$\tan\frac{\alpha}{2}=\frac{d\cos\frac{\delta}{2}}{2\rho}\,;$$

or, substituting for ρ its value $2f\left(1+\cos\frac{\delta}{2}\right)$, where f is the focal distance of the mirror,

$$\tan\frac{\alpha}{2}=\frac{d\left(\cos\frac{\delta}{2}+\cos^2\frac{\delta}{2}\right)}{4f}.$$

Having thus determined the theoretical spreading, one determines the actual amount by measuring the angle of the beam, and the ratio gives an idea of the correctness of form of the reflector. This ratio is for the present Schuckert mirror 1:1·08, the deviation from parabolic form being thus extremely small. Of course, this method is not susceptible of very great accuracy, owing to the difficulty of determing the diameter of the crater and the angle of illumination of the beam, these being indefinite owing to the gradual manner in which the carbon passes from white heat to blackness in passing from the crater to the outside. Another method for determination of defects of shape in the reflector is to observe the shadow cast by a ruler or other straight-edged object. The smallest fault in the mirror, quite undiscoverable by measuring instruments, gives irregularities in the shadow. More exact results are obtained by the third method, that of Tschikoleff. The glass mirror in its

holder is placed in front of a screen roughly divided, with the axis of the reflector perpendicular to the screen. The latter has, arranged centrally, an opening in which is fixed a photographic lens. The screen is painted black and divided by white lines 5 mm. wide into compartments, or squares of 50 cm. per side. If the screen be illuminated by arc lamps placed alongside, there appears on the ground glass of the camera attached to the lens above mentioned, a picture of these lines when the screen is at a certain distance from the mirror, and this picture can be photographically enlarged. The images of the lines must be regular continuous curves, and the smallest defect shows itself in an irregularity. The limits of allowable irregularity are not easily defined; and a mirror should be kept as a standard which has passed the first test mentioned, and all worse than this should be rejected. This method of Tschikoleff does not give any information as to the approximation of the mirror to parabolic form; it merely tests for regularity of shape. Tschikoleff recommends that an accurate template be made, and the final determination performed thus: The mirror is set up in a suitable frame with a lamp in its focus and the reflected light is caught on a screen set up a few metres away—the field of light on this must be as even as possible, and rings of light in the spot show inaccuracy of form.* Here again only experience can determine how far irregularities may be permitted.

The above tests are only necessary to convince minds which are prejudiced against glass parabolic mirrors; and when once anyone is convinced of its advantages the second method, of measuring the angle of the beam, will be quite sufficient. The table herewith gives an idea of the performance of the Schuckert mirrors. If we take in this table the value of the illumination for a mirror of 60cm. diameter with a 40-ampere arc, we find the value 24,900,000 standard candles. In the experiments of the Austrian military authorities, 20,000,000 standard candles was the value measured at 2,050 metres distance. This makes the value of atmospheric absorption at 10·4 per cent. per kilometre, a value well within the bounds of probability. Above 60 amperes there are no reliable observations and only approximate values are given, resting on the observation that above certain values raising the current does not increase the illuminating power of a projector.

So long, therefore, as the author's statements as to the illuminating power of projectors are supported by evidence, while no proofs are brought to the contrary, we may be permitted to accept the figures given by Messrs. Schuckert as correct.

It might appear open to question whether the old statements as to projectors should not suffice us, without introducing the new standard of the illuminating power of the beam. We may, therefore, consider a little more nearly the older statements. Up to a few years ago the French firm of Sautter, Lemonnier and Co. were the only authorities on the construction of projectors, and we find in all their publications that they took the intensity of the radiation from the source to the mirror as the standard of reference. In some cases they specified the "pouvoir condensateur," but generally the description was projectors of 600, 2,000, or 4,000 carcels. As a rule the distance at which objects could be discerned was also given, under the understanding of a clear night, bright colours on the illuminated object, and often a certain size therefor, besides a practised observer in a good position. These conditions are naturally extremely indefinite, and for purposes of comparison are quite valueless. So that against the statement that the Spanish Government sent to Melilla a Mangin projector 80cm. in diameter which made objects 5 kilometres away easily discernible, and which was far superior to the Schuckert instrument, may be set the counter-statement that in the Gulf of Ismid, with a 60cm. Schuckert projector, objects 9·8 kilometres away were clearly seen. Both statements are valueless, except for the purpose of throwing dust in the eyes of the uninitiated. The atmospheric absorption, varying from 2 to far over 50 per cent., entirely vitiates such observations. It may be shown mathematically* that the seeing distance is proportional to the fourth root of the illuminating power of the projector. If, therefore, we take a projector better by 36 per cent. than a second, we find that if the latter has a sight distance of 1,250 metres, the former has only 1,350 metres. To raise the sight distance from 3,000 metres to 3,300 metres, or 10 per cent., would require a mirror better by 50 per cent.

It is then abundantly clear that photometrical observations at the place illuminated are the only possible means of comparison, and they avoid all errors due to fatigue or dazzling of the sight. The author thinks that the attempt of Messrs. Schuckert to break with precedent, and to put the question of projector measurements on a sounder scientific basis, should meet with support from experts, and does not deserve to be decried as it hitherto has been by those who should only have a scientific interest in the questions at stake.

Electric Traction in Italy.—A contract has just been secured by the French Thomson Houston Company for the construction of an electric tramway between Varese and Santa Maria de Montana. The line will commence at the Varese railway station and pass through the town, and through the village of Saint Ambrose, terminating at Santa Maria de Montana. The line will be a single one with a gauge of 3·6ft. It is said that only about 10 per cent. of the whole line will be on the level. The rolling stock will comprise four motor cars, each fitted with two 25-H.P. motors, and capable of accommodating 50 passengers each. There will also be four ordinary cars to act as "trailers."

HERMANN VON HELMHOLTZ.

A prince and a great man has fallen in the ranks of science, a rich and matured judgment is lost to the world. The century which has witnessed such a blaze of scientific genius is becoming rapidly impoverished of its great men in almost all departments, and to all appearance it seems unlikely to carry many of its typical heroes over into the twentieth century. There are not wanting prophets who foresee a critical period for science in the near future, writers who suggest that, unless scientific men band themselves together, the hostile powers of dogmatic theology on the one hand, and of aggressive ignorance on the other, will close in and temporarily destroy it. That part of science which leads direct to practical applications is no doubt safe in the hands of the coming democracy, but into the higher regions and upper air of pure science itself the outlook is not so clear. A period of neglect is not an impossibility; perhaps it may even be held that such a period would in some ways be useful by giving time for the mass of already acquired knowledge to be assimilated; time for it to soak into the minds of the people. The progress made during the lifetime, and largely by the aid, of such a man as VON HELMHOLTZ is something enormous. Our ideas on a number of fundamental subjects have been revolutionised within the last fifty years, and glimpses have been caught into regions of which the average man is not yet even dimly conscious. Continual progress at this rate seems well-nigh impossible, and were it possible it might be useless; for what the average man cannot even begin to assimilate remains undigested, and must in the course of time be either extruded or ignored. The advance of science into regions too hopelessly beyond ordinary capacities and intelligences must need for its permanence either the continuance of a race of giants, such as we have been and still are familiar with, or else the raising of the average level of knowledge and intelligence to an unprecedented and probably impossible extent. When the general feeling about any branch of science is that it is in the air, and too lofty for sublunary consumption, then, however admirable and coherent it may really be, for all practical purposes in the air it is; and when its holders and supporters die, it may be expected to float away beyond the ken of those who remain, until a new race of geniuses arrive, and mankind in general has advanced to a higher plateau of thought.

Digitized by Google

These thoughts apply less directly, perhaps, to the work of von Helmholtz than to the work of some other men of similar magnitude. The extraordinary combination of power which he possessed, the many-sidedness of his character and knowledge, his power of expressing himself with fair simplicity in ordinary language, have enabled him to tether permanently for the use of mankind much elevated floating material which otherwise would have been out of range. And in this he has been fortunate in not being alone. He has been one of a race of giants, and he has had the advantage of a great school of disciples and co-workers, eager and well-instructed men, who have, with industry and ability, seized and secured and developed one discovery after another as they emerged from the mint of his genius.

His work in acoustics and optics in connection with the ear and the eye is well known, and has given a great stimulus to workers, especially to workers in the subject of physiology, sometimes stimulating them to agreement, sometimes to divergence of view, but always leading to activity and discussion and progress. His work on the application of the principle of the "Conservation of Energy to Physics," in 1847, has now become almost a commonplace of science. No one doubts now that Leyden jar discharges are oscillatory, or that the mechanical power of electric motors depends on the back volts generated in their armatures, In more recondite regions he first showed how to apply mathematics to the more difficult problems of hydrodynamics, and thus rendered possible that treatment of vortex motion which appears destined to play so enormous a part in the semi-ultimate explanation of the physical universe. On this must be based in all probability the theory of matter, the theory of ether, the theories of gravitation and of cohesion. To have been at the origin of such a wide-embracing theory as this transcendental hydrodynamics may not improbably in the future seem to posterity to constitute Helmholtz's greatest title to fame.

We of the present think more of the ophthalmoscope, or of his work in connection with practical units of electrical measurement; and we even go so far as to permit one great man to be sent on a bootless errand to Chicago, there to discuss trivial questions about practical electrical units, and to help decide the momentous question whether a unit of self-induction shall be called by the name "Henry" or by some other euphonious appellation. Whatever the merits of this trip to Chicago, it has not been accomplished without cost to the world. The age of 73 is in some senses and for some lives a ripe age, but a man like Helmholtz should have lived longer. That the peaceful, placid existence represented in his own most beautiful autobiographical sketch should have been terminated in such a senseless manner; whether the journey was undertaken at the beck of a headstrong and self-sufficient young man on whom the Germans have chosen to confer unwieldy power, or whether it was undertaken for some better reason, cannot but be regarded as a terrible pity. It may be true that at 73 a man's most active work is done, his main lines of thought matured; but how valuable may not such a ripe power and matured judgment be to the world! Has the world many such men, that it can afford to throw them away so lightly?

This same autobiographical sketch of Helmholtz must become better known. As a pamphlet for private circulation it was translated a year or two back by Dr. Atkinson; but, though brief, it ranks with the life of Darwin in the insight it gives into the calm, clear-sighted, modest, vigorous, and patient thoughtfulness which characterised both these great men: it is a lesson to this fevered age concerning the atmosphere in which discovery is possible, of the mode of working of a true genius, of the manner of man to whom inspiration is almost a daily experience.

Helmholtz is usually thought of as a physicist, a physiologist, and a mathematician; but even this wide range did not exhaust his sympathies and interests. The new science now struggling to the birth—that of experimental psychology—welcomed him among its most powerful, though silent, sympathisers. He attended the last congress in London before going to the Edinburgh meeting of the British Association, and the hardly-discovered facts, now being at last rescued from superstition and placed upon a scientific basis, found in him no cold disdain nor surly opposition, but a friendly countenance and helpful criticism.

Well, he has gone, and we are the poorer for his loss. The services of such a man are not to be limited by national boundaries, nor acknowledged with constricted gratitude; he belongs to the world and to nothing less. The possession of great genius is a great responsibility; not every nation is worthy of it. Fortunate were the German people in receiving in their midst so indomitable and persevering a worker, so single-hearted and estimable a man; and they have proved themselves worthy of the trust. All his later life they have held him in highest honour, and they provided him with material resources such as no other civilised nation at the same epoch was likely to bestow. Honourable his life has been, both to man and nation, and the world, though blind to many things of high and noble import, has in this case no cause to regret that the man came before his time, or that he spoke to a faithless and perverse generation.

SOME NOTES ON THE GOVERNING OF STEAM ENGINES, PARTICULARLY WHEN COUPLED TO DYNAMOS.

BY G. L. ADDENBROOKE.

This is a subject which has always been in my mind in connection with central-station electric lighting; and the fact that it has been brought into prominence by Mr. Swinburne, in his simple but lucid Paper before the British Association, shows that the question is now beginning to attract the attention which it deserves.

Mr. Swinburne says that the governing of engines, particularly small ones, is generally better attended to on the Continent than in England; the reason, I think, is that although our neighbours may be less particular and less thorough in some points than we are, yet they are more accustomed to treat matters as a whole, and to take into account conditions which the ordinarily trained executive engineer in this country considers as subjects for discussion by theorists at the societies; but which he, in his capacity of having to make things go, need not concern himself with.

That is one way of looking at the question. The next is that for most industrial applications the governing of the engines for many years has been amply good for all practical purposes, so that there has been no need to devote special attention to it. An exception must here be made as regards marine engines, the difficulties in governing which in a rough sea, when the screw comes frequently out of water, have never yet been satisfactorily overcome, although a great amount of time and care has been devoted to perfecting different forms of governors for this purpose.

In order to understand the exact position of matters at present, as regards the governing of the engines used for other than marine purposes, it is advisable to look back a little at the history of the steam-engine governor, and the purposes to which it has been chiefly applied up to the present date, premising the fact that so far electrical engineers have not paid any very great amount of attention to the problem, as they

Digitized by Google

have been occupied by other considerations of more immediate importance, and have been generally content in this particular to accept the practice of industrial engineers, and to rely on their judgment as having the greater experience.

Steam-engine governors were, I believe, first used on pumping engines, and their main object was to prevent the engine running away when the pump rods or any other important moving part broke, and the engine would, unless controlled, have run away and probably wrecked itself. For doing this a very rough style of governor was sufficient.

The use of winding engines in mines did not advance matters much, because, although a more sensitive governor is desirable, yet the driver generally controls the valve motion largely himself, as this is more convenient—the engine being used for short periods and being frequently reversed.

Engines were next applied to driving forging and rolling plants in ironworks; and here a governor is essential, as the strains vary so quickly when the material is being passed through the rolls. A comparatively rough governor is, however, sufficient, as the moving masses are usually very heavy, and exact equality of speed is not absolutely essential.

What really caused careful attention to be paid to the construction of governors and valve-gear was the application of steam engines to driving spinning machinery, the rise of mechanical weaving and spinning, and of the best modern types of steam engines, being almost contemporaneous. For a loom to work properly, regular speed is essential, or the shuttles will not throw properly, and uneven strains are produced in the material. Not only, therefore, has the best steam practice been usually devoted to the construction of engines for driving textile factories for the sake of economical working, but at the same time the utmost pains have been taken to design valve and governing gear which would admit of the engine's doing its work at a constant speed whatever the load. The latter condition was essential, because only one engine was usually employed for driving at a time, though the load would constantly vary as different machines were thrown in and out; and at times a part of the factory might be altogether closed if work in one of the departments was slack.

The engineers who devote themselves chiefly to the construction of mill engines have for many years been able to meet these conditions, and to supply plant which would readily retain a speed within 2 per cent. or 3 per cent. of the normal, whatever might be the load. It is true that large fly-wheels and comparatively slow speeds have hitherto been chiefly in vogue for this class of plant, but this is a somewhat minor point.

Such being the state of affairs when electric lighting first became practical, electrical engineers naturally turned to the constructors of mill engines for advice and help; the result was the application of the mill engine, with rope driving, to turning dynamos, a system which has worked well wherever it has been properly applied, while for freedom from breakdowns and exactness of working this method has probably not yet been surpassed. Such plants, however, occupy a great deal of space, are rather expensive, and there is a certain loss of power in rope driving. Consequently the high-speed engine has been developed to get over these difficulties, so far, chiefly of the single-acting type; but now that the conditions of running of such engines is better understood, and confidence in high-speeds is increasing, there are indications that similar engines, but double-acting, will gradually come to be preferred.

Our cursory glance at the history of the application of governors to engines has now made it manifest that the best practice hitherto has been in the construction of governors to produce perfectly even motion, whatever the load. Further, it must be noted that such engines have usually been engaged in supplying energy direct in the form of motion to lines of shafting and to machinery which it is required to run at a constant speed.

Let us now turn to the driving of dynamos by means of steam engines. The proper methods of governing such engines will naturally depend on the purposes to which the current produced is to be applied. If for the transmission of power or the running of arc lights in series, very little alteration of existing methods is required; but if the engine is used for lighting incandescent lamps direct, whether for a private installation or in a public supply station—which latter is, of course, the most important case, and the one to which it is proposed to devote most attention—then it is desirable to clearly define the limiting conditions of the problem; so that, knowing exactly what is required, we may be in a position to judge how far existing appliances meet the conditions, and where they are defective, and thus arrive at a definite idea of the directions in which alterations and improvements are required.

Now in a central station, the ultimate object is the incandescing to a certain point of carbon filaments, to procure from which the standard amount of light—16 candles from a 16 c.p. lamp—the pressure or voltage must be steady and exact, within one per cent. on either side of the normal, any further variation either way making a great difference in the light. It is true the Board of Trade permits a wider variation than this, viz., 4 per cent.; but this is extreme, and greater than ought to be permitted in any well-regulated station, since 4 per cent. variation in the pressure of the supply means 25 per cent. variation in the light given by the lamp, besides a change in colour if the voltage is reduced, or premature destruction of the filament if it is increased.

The obtaining of an even pressure over a district is a question of the system of supply and the design of the mains, and one we are not dealing with here. All we need gather for our present purpose is that the supply, and consequently the running, of the engines must be regular under all conditions, whether lamps are turned on and off, and, secondly, some predetermined voltage also must be maintained at the station terminals, differing at different times of the day to allow for varying losses in the mains as the load alters.

Perhaps, in order that we may present to ourselves a clear idea of the conditions, an entirely mechanical analogue may be useful. Let us suppose that the engine-room in a central station is the engine-room of a large mill which is worked by several steam engines, driving by means of pulleys and friction clutches on to a line of counter-shafting. Imagine that these clutches are not very well designed, and that there is always a certain amount of slip in them, not more than six or seven per cent. at light loads, but increasing considerably at heavy loads. It is, of course, required to keep the mill machinery running evenly within two or three per cent. If the load is a light one not only will the engine or engines be lightly loaded but there will be very little slip in the clutches; on the other hand, as the work done in the mill increases and becomes heavy, not only will the load on the engines increase, but, having to keep the mill machinery revolving at a constant speed, the speed of the engines will also have to be increased to make up for the extra motion lost in the clutches, the friction of which will absorb energy, which will be dissipated as heat as the losses in dynamos are. Under these circumstances it is clear that it will not be sufficient if we have a governor which keeps the engines running always at the same rate: we must over-govern to some extent, that is, we must not only have the speed of the engine always under control. but we must also have an arrangement by which the engine shall go a certain percentage faster at heavy loads than at light. We may diminish the difference of slip at different loads by improving the efficiency of our friction clutches, but the fact remains that it exists to some extent and that it must be compensated for.

In an electric lighting central station the dynamos may be regarded as the friction clutches in the above simile. Besides a certain loss of power greater at heavy loads than at light, and which may be likened to the loss in friction in the clutches, there is also a loss of motion. increasing with the load, due to self-induction and the back action of the armature current on the fields, which weakens them and necessitates the speed being increased to obtain the same voltage; this is like the slip in the friction clutch. If not corrected by outside influences it may amount to from 10 to 20 per cent.

In the central station there is the further point that at the hours of heavy load it is necessary to run at a higher speed altogether than at light loads in order to keep up a higher general pressure in the mains to allow for increased loss in them.

Digitized by Google

Consequently, in driving dynamos in central stations for lighting, we have not only to secure regular running or absence of sudden variations of speed at all loads, but we have got to provide, taking the light load as a basis, that as the load increases the driving speed shall be increased in order :—

1. To increase the pressure on the mains.

2. To overcome the increased armature resistance and provide increased excitation of the field magnets.

3. To make up for the slip or loss in pressure caused by the increased back action of the armature on the magnets and increased self-induction, which necessitates a higher rate of driving, though it does not directly mean loss of energy.

It is true that it is not absolutely necessary to increase the speed of the engines, it may be kept constant at all loads as in mill engines, and the requisite variations may be produced by the use of resistances or by varying the excitation of the dynamos, by means of resistances or the use of a separate exciting engine.

SWINBURNE DYNAMOTORS AND MOTOR GENERATORS.

The machine illustrated in Fig. 1, which was made for University College, Bristol, to the order of Prof. A. P. Chattock, by Messrs. Swinburne and Co., is a small direct-current motor or generator

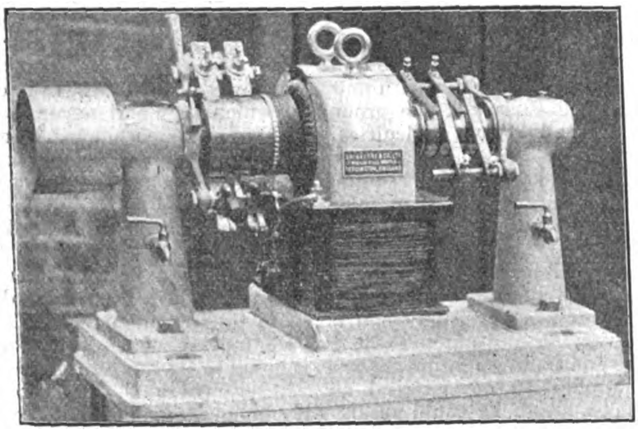

FIG. 1.

fitted with four slip rings. Driven by a belt, it either gives a direct current, or excites itself and gives an ordinary alternating cur-

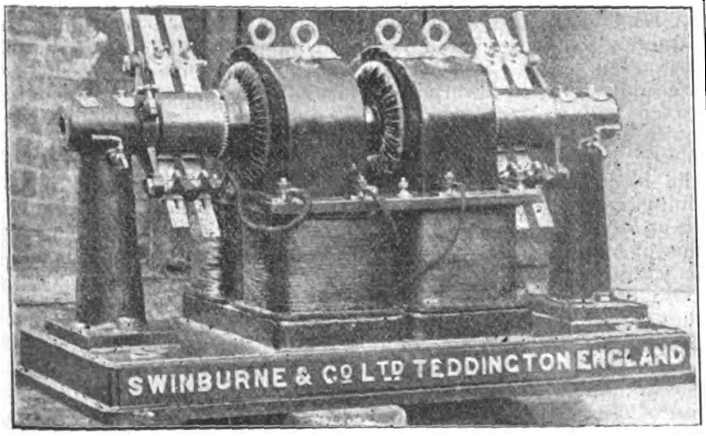

FIG. 2.

rent of low frequency from two of the slip rings. If three of the slip rings are used, a triple alternating current is obtained. The machine may be fed with a direct current, and will then give a much larger alternating current output; for as there is only one armature winding, the wires have to carry comparatively small currents for most of each revolution. This machine is intended for use in laboratories, technical colleges, experimental shops, &c., in place of Messrs. Swinburne and Co.'s ordinary B type motor alternator, where cost is a principal consideration, and the comparatively low frequency does not matter.

The dynamotor shown in Fig. 2 is for charging cells in central stations. In many cases it is a serious expense to arrange for dynamos to give the full charging pressure, it is much more convenient to use a dynamotor for giving the odd 25 or 50 per cent. extra pressure needed for charging. A dynamotor of this sort can also be used for charging and discharging all the cells uniformly on the mains, so that one cell is not worked more than another. This is of great importance in battery stations, as it increases the life of the cells, and saves the complications of charging and discharging switches.

A small machine has been made by Messrs. Swinburne and Co. for working a telephone exchange off the town mains, without trouble from want of insulation. The armature is wound with two circuits which are very highly insulated from each other, so that the telephone system can have earth returns without any complications due to the network of electric mains getting power from the same sources. The insulation between the windings is practically infinity.

THE THREE-WIRE TROLLEY SYSTEM AT BANGOR, ME.*

BY J. G. CARROL.

Having noticed an article in one of the electrical journals suggesting the feasibility of operating an electric railway by the three-wire system, I became much interested, particularly as the road I am connected with has been using that method for some three years. The article stated that such method was possible or practicable only on double-track road. I will endeavour to make clear how it is possible to operate a single-track road by such methods. In the first place, our power plant being situated 4½ miles from the nearest point of the road, it was necessary that some means be devised to avoid the enormous expense that would be incurred in getting the copper wire necessary to have a metallic circuit. We tried in the first place to get a ground return by putting copper ground plates in the river at different points along our route and at the power station; but to no purpose. A portion of our line, 2½ miles long, situated in the city of Brewer, is connected at each hydrant with the rail, and as we operate the water system of that city, and the pumping station is in the same building as the railway power plant, this gives us a good return when needed. But, operating as we do now by the three-wire system, this is unnecessary when in balance. We have 7·74 miles of single track with seven turnouts. The rail is 35lb., one-half tram and the balance T. The system consists of two distinct roads, one in the city of Brewer, about 2½ miles long, and the other in Bangor, 5¼ miles. By reference to the map it will be seen that there is no connection between the two. The rails are bonded at the joints with No. 4 copper bonds, and connected at each joint with a supplementary No. 4 copper wire.

Our power plant consists of four Thomson-Houston generators, driven by four Holmes turbine wheels of 120 H.P. each. Our equipment consists of two F-30 motors under each car. We operate in regular service nine motor cars, and nearly every week-day run three additional motor cars, drawing three trail cars. We connect our generators as in Fig. 1, each two machines being connected in multiple. For convenience we will call two machines on one side A and the other two B. The positive side of group A is connected to earth, and the negative of B to earth; the positive of B to line, and the negative of A to line. From B is run a main composed of five No. O wires, and from A is run a main of four No. O wires. The mains terminate at a point near the centre of the city, and three feeders are run from B to different points along the positive trolley wire, while two feeders are run from A to the two sections of negative trolley wire indicated by the map (Fig. 2). It will be seen that there are two trolley wires from X to Y. From one of these a branch runs to Z. The wires from X to Y are of different polarity, and of course carefully insulated from each other. The use of two wires does away with

* From the *Street Railway Review*.

the use of overhead frogs at turnouts, and serves another important purpose in the balancing of the system, which will be explained later.

In order to operate successfully the load on each side must be equal, or nearly so. This we accomplish in the following manner : Our time table and turnouts are so arranged as to admit of a 15 minute schedule. Every 15 minutes four cars are at X, and at the same time three are at the ends of the routes 1, 2, and 3. This applies to the Bangor divisions. At the same time two cars are at the ends of the line on the Brewer division. In operation one car

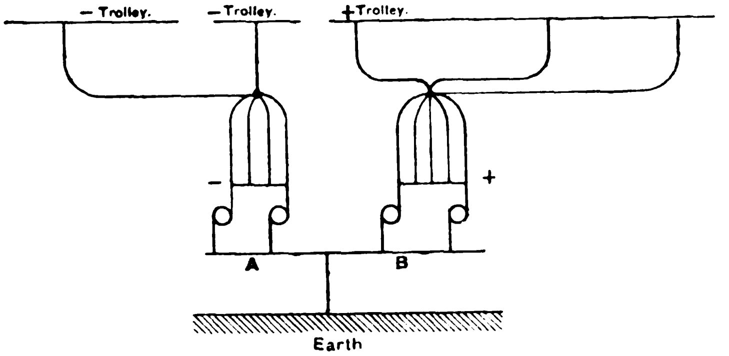

Fig. 1.

bound from X to Z takes the negative wire. One car bound from X to Y takes the positive wire. One car is bound from X to F and one from X to R on the positive side. This arrangement gives us five cars on the positive side and four on the negative. As long as this balance is maintained, everything runs smoothly. In putting on extra cars we have occasion to run them only from Y, which is a point opposite the fair grounds, to X, which is the business centre of the city. By making these extra cars use alternate wires this balance is still maintained. We have a number of heavy grades and short curves. In fact, there is scarcely a level

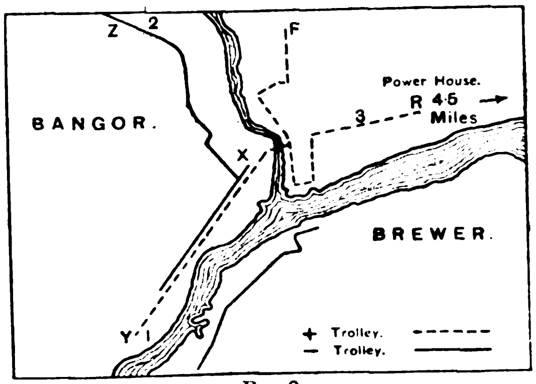

Fig. 2.

piece of track in Bangor. For instance, on the Pearl-street line, we have a grade of 6 per cent. for 200ft. ; on Main-street one of 8 per cent. for 100ft. ; on Olive-street one of 7 per cent. and two of 5 per cent. ; on Center-street one of 8 per cent. for 200ft. ; and in Brewer four of 6 per cent., one of which is 500ft. long.

The one bad feature of this system is that in case of a generator getting disabled we are out of balance by having two machines on one side and one on the other. This we intend to remedy by having a spare generator ready to put in on either side, as may be necessary.

THE ELECTRICAL EQUIPMENT OF THE LIVERPOOL OVERHEAD RAILWAY.

BY THOMAS PARKER, M. INST. C.E.

(*Continued from page 555.*)

DISCUSSION.

Mr. Alfred Giles, President, said that if there was any truth in the old adage that in the multitude of counsellers there was wisdom, the Papers before the meeting should prove it. He was sure, in considering the advantages offered by the Overhead Railway at Liverpool as compared with the pattern which it followed, the Elevated Railway in New York, the Institution was very much indebted to the authors for the investigations they had made, and he called upon the members to accord to those gentlemen their most cordial thanks.

Mr. J. H. Greathead wished to add one or two words by way of explanation. The first Paper gave two tables, one or two points of which he wished to emphasise. The first had reference to the weight of electric motors compared with steam locomotives. On the Liverpool Overhead Railway the electric motors weighed 20 per cent. of the total weight of the train exclusive of the motors, whereas on the Metropolitan Railway in London the locomotive weighed just double, say 40 per cent. of the weight of the train. On the other hand, the tractive effort of which the electric motors were capable was, in the case of the Liverpool Overhead Railway, 120lb. per ton of train, compared with 71lb. per ton of train of which the steam-locomotives were capable. That seemed to be a very important point. There was also another feature, that not only could a much greater tractive effort be obtained by electricity ; but, by adopting motor carriages, a correspondingly greater adhesion was secured. Table B illustrated that point, because on the Liverpool Railway the adhesion was 115lb. per ton of train, whereas on the District Railway, calculated in the same way, it was only 61lb. per ton of train. And, finally, the maximum tractive force per ton of motor or locomotive was very striking. On the Liverpool Railway electricity gave 730lb. tractive effort per ton of motor as a maximum at starting, while on the District Railway the tractive force was only 234lb. per ton of locomotive, or less than one-third of that obtained at Liverpool in starting the train.

Sir William Forwood said he felt it a great honour and privilege to be permitted to be present to listen to the two able and instructive Papers which had been read. During the past four or five years he had been pretty well saturated with all that appertained to overhead railways, but he had still learned a great deal that was new and interesting from the Papers. He was the chairman who had survived the construction of the Overhead Railway, and as such was entitled to some congratulation ; for though it had bristled with a great many problems which had been a source of vast interest to the engineers of the line, it had also been full of difficulties which had caused the Chairman and Directors of the undertaking many headaches. They had published a prospectus undertaking to construct the line at a certain cost, and naturally they had been asked to live up to that prospectus ; and when they were faced day by day with new developments, with drains underneath the surface of the ground of which they had never heard, and with all sorts of difficulties which meant a considerable extra cost to the shareholders, it naturally was a matter of some anxiety to the Directors. He was glad to be able to say that after ten months' working, the shareholders had been paid not only a preference dividend, but also 1 per cent. upon ordinary capital. This was entirely due to the employment of electric traction for the railway. Naturally, as a layman, he could not pretend to enter into many of the scientific problems which had been treated in the Papers, but perhaps some of those present might say, "This is a very interesting railway, but what practical use is it going to be ? is it an experiment, or is it going to be the forerunner of the application of electrical traction elsewhere ?" That was a point on which he could speak. He believed, from all he could see, that it was going to be the forerunner of the application of electrical traction on a very considerable scale ; for when the construction of the line had been nearly completed, which was a great improvement upon any elevated railway in America, the means to be adopted for traction had to be considered. The line was commenced with the idea of using steam, which was used upon the overhead railway in America ; but after visiting America, and seeing what had been done in electrical traction, he felt that in England, if possible, something better than had been done in America should be attempted, and he was proud to say it had succeeded. There was nothing in America comparable with the electric railway in Liverpool. Naturally the Directors were face to face with two problems. In the first place, they wanted to be quite sure that the railway would be economical if worked by electricity, otherwise they would soon have found themselves in the bankruptcy court ; in the second place, they wanted to be quite sure that it would be a reliable railway, otherwise it would be utterly useless to adopt electricity as the motive power to convey men of business hurrying to and fro in their daily vocation. It was only after very deliberate consideration that they were able to decide upon the adoption of electricity. They had the advantage of the experience gained on the City and South London Railway, and also of what had been done in America, and they had made up their minds—not without considerable misgivings—to go in for electricity. The cost of steam plant would have been £37,000 ; the cost of electrical equipment was £67,000 to £70,000 ; therefore, the first outlay was very considerable ; but, having made up their minds to employ electricity, they were determined—acting under the advice of their engineers—to have the very best electrical equipment that could be obtained, and their success was due largely to the accomplishment of that resolve. It was agreed that the manufacturers who supplied the electrical plant should be compelled by contract to run the line for the first two years at a given price

Digitized by Google

per train mile. He did not know that it had had a great effect upon the contractors, because he believed that they would have done their work thoroughly well in any case; but, at the same time, it was a prudent course for the Directors to adopt. He was glad to say that the result had been very highly satisfactory. In the first place, with regard to cost, the Electrical Construction Corporation had been paid 4d. per mile for traction during the first ten months of working. Their outlay was carefully watched, and finding that the trains were running with perfect regularity and without break-downs, and finding also that the contractors were making money out of the contract, at the end of that period, though the contract ran for two years, the Company stepped in and said—"Gentlemen, we put an end to your contract." And since the first of January last the Company had been running the railway on its own account. He was glad to be able to state that this had resulted in a saving in January of £150; in other words, 5½ miles of railway were run at a cost of 3½d. for locomotive expenses. He thought that was very satisfactory. The engineers had stated—and he fully agreed with them—that when the line was opened to the length of seven miles, a further reduction would be made on the 3½d. Then came the question as to reliability, because if the railway was subject to break-downs it would soon lose the passenger traffic. He might state that there was an enterprising line of penny omnibuses running the whole length of the railway, and had there been many break-downs on the line, the traffic would soon have been transferred to the omnibuses below. But since the opening of the railway ten months ago, although a five minutes' service of trains had, with the exception of the first two months, been maintained, nearly 96 per cent. of the trains had been punctual, and during the last week but one, 99 per cent. of the trains were punctual. That was a record which he did not think was equalled in the railway world, but the experience of those present was no doubt much greater than his own on that point. The railway had given much satisfaction to the commercial community of Liverpool; not only was it regular, but there was an absence of noise and dirt, and it was a perfect treat to ride upon the Overhead Railway. There were ladies who made frequent journeys in the day for pleasure. That statement might provoke a laugh; but he could assure the members present that, on visiting Liverpool, they would not be satisfied with one journey upon the Overhead Railway. It disclosed one of the finest prospects in the country. It passed along the whole line of the docks, and afforded passengers a view of some of the most magnificent ships in the world. Beyond the docks was the estuary of the Mersey, which of itself was a sight which had few equals in England. He would say to all the members and associates of the Institution, that the Directors would be delighted whenever they came to Liverpool if they would call at the office, and ask for an order to see the railway and the generating station. He gave that invitation in the sincere hope that it might be availed of. He wished to acknowledge the sense of the great services that the Directors had received from their engineers, Sir Douglas Fox and Mr. Greathead, and also from Mr. Parker, who had been in charge of the electrical equipment of the line. Of course it was a novel thing. He knew that the Directors had felt timid on many points; they were thankful for the courage their engineers had given them on hose points, and he hoped within the next few years the railway would be completed for the whole distance originally contemplated; he also believed, before any great length of time elapsed, the Company would be able to pay a 5 per cent. dividend to the shareholders. That was a point to which he attached great importance, for although engineers might think only of constructive success, the question was, after all, one of dividends; and he was sure that all would be pleased that this, the first real electrical railway in England, had not only given satisfaction to the travelling public, but was also earning substantial dividends for the shareholders.

Sir Douglas Fox had desired not to speak until he had heard some criticisms upon the Papers, but responded to a call from the President. He might say, as Sir W. Forwood had so very well put it, that the problem, which had been to some extent solved at Liverpool, was one that had caused a great deal of anxious thought to all connected with it. The engineers owed a great deal of their success to the fact that they had practical men at the head of affairs in connection with the Company. The Directors were, without exception, Liverpool men; they knew what was required to accommodate the traffic, and, with the plain common sense which was found in that city, they told their engineers exactly what they wanted, and so made the duty of providing it much simpler. Not only so; but he wished to say that his colleague Mr. Greathead and he had felt that they were exceptionally fortunate in several circumstances surrounding the arrangements in connection with this work. Not only had they had a Board of Directors who showed full confidence in them from beginning to end, and such excellent representatives in Liverpool as Mr. Francis Fox and Mr. Cottrell; but they had in their contractor, Mr. Willans, a mechanical engineer of considerable talent, who, with his able assistant, Mr. Hudleston, had done everything in his power to assist in the work. Mr. Hudleston's assistance had been especially valuable. The railway, as shown on the plan, might look very simple; but he could assure the members that, in his experience, he had never known a case in which there was so much intricate adjustment necessary, before it was possible to lay out the line in its present perfect state. It had to be literally threaded through the midst of a very complicated system of cross-over roads, dock-lines, warehouses and existing railways, and the engineers were tied on every side by the authorities, headed by their kind friends (for they had shown every desire to assist the Company) Mr. Lyster, the Dock Engineer, on the one side, and Mr. Boulnois, the City Engineer of Liverpool, on the other. The fact that Mr. Hudleston had been formerly an officer of the Dock Board, and, therefore, thoroughly understood their requirements, had enabled him to give great assistance to the engineers in carrying out their arrangements. Not only was that so, but a great deal of ingenuity was exercised in connection with this work by those holding somewhat subordinate positions. The clever and novel way in which the erection of the structure was carried out had been described. It was found desirable, for economical reasons, to deliver all the ironwork at the north end. There was a convenient yard connected with an existing goods station, and the whole of the material was there delivered. It was decided by the contractor to commence at one end and work over-hand, and that had been done for nearly six miles. Although at first sight that might seem to be a slow process, it worked out exceedingly well, and a good deal of the detail was well executed by the sub-contractors. There was also considerable difficulty at first in connection with the manufacture of the steel plates for the platform of the viaduct; and here, again, in connection with the Phœnix Foundry Company, a Member of the Institution, Mr. Goodwin, had rendered valuable assistance. What was desired with reference to this railway was, first of all (and there came in the influence of the Directors), to have an economical, and at the same time a thoroughly durable, structure, which could be cheaply maintained, and which would be, as far as possible, fire-proof, because the line ran through a very inflammable neighbourhood. Ever since the opening of the railway it had been proved how important that was, and how utterly fatal it would have been to have adopted a timber structure. A large timber-yard had been on fire, the flames passing right across the railway, but doing it little or no damage. Of course they were tied, as engineers unfortunately almost always were, for headway, and, consequently, were obliged to introduce the bracing necessary to resist wind pressure in a very cautious manner, and just get it in where it was possible. One of the important things necessary was to decide upon the most economical span for the normal structure. That was a matter which his colleagues and he had discussed very fully; and, rightly or wrongly, they had come to the conclusion, that, with piers of that height, the most economical span was 50ft. They called it the normal structure; but it was rather a case where the exception proved the rule, for only one-third of the length was normal, and two-thirds of it were composed of abnormal spans. That was, of course, due to the inter-threading that he had spoken of. They commenced with the idea that for a considerable length they would be able to escape this inconvenience by deviating the lines underneath; but, in spite of a large expenditure upon such works, they had been obliged to introduce abnormal spans to the extent above mentioned. In connection with that he wished to mention that over £80,000 out of the total cost was represented by the slewing and repaving of the dock lines underneath the structure, and the accommodation works. When they had resolved upon the 50-foot span, the next most important point was, what sort of floor were they to have? They wanted as noiseless a floor as possible, which would be easily accessible for painting, which would be very stiff vertically, which would tend to help them in the cross-bracing of the structure, which could be cheaply and rapidly manufactured and be easily made water-tight. After a good many designs were considered, they at last fixed upon the "Hobson" system, it being the first time, he believed, that it had been used, and that certainly had given great satisfaction. He would not weary the members with lists of figures, but he should like to direct attention to the results of the testing of the flooring as given in the Paper. A very important point was, as usual in the case of passing through towns, to make the structure drop-dry. Those who had any experience of that requirement would appreciate the sorrows of engineers; but they had done their best in that direction, and, he thought, had been fairly successful, thanks to that particular flooring. They had found from experience—learning always more by mistakes than by successes—that, among small matters of detail, it was important, where that or any similar flooring was used, not to attempt to mix sand with the asphalt, but to put in pure asphalt in spite of the additional cost, for that saved trouble afterwards. The platform had given wonderful stiffness to the structure, and it had proved even quieter than had been anticipated. He had been rather afraid there might have been a severe drumming noise, but there was not. It was less noisy than most plat-

Digitized by Google

forms which trains ran over, and that, combined with strength, was a great adxantage. It allowed perfect ventilation of the permanent-way timbers, the attachment of the rails by means of fangbolts without impairing the insulation of the electric conductor and a proper system of drainage. The question of foundations was a matter requiring some consideration, when it was remembered that there were at least 1,200 separate piers; and, if anything in the way of a luxurious foundation had been attempted, it would very soon have been heard of in the cost. As a matter of fact, nothing could be simpler than the system adopted—a block of concrete, bolts built into it, and a wrought-iron column fixed by those bolts direct on to it, and then the column protected by a very effective cast-iron boss, which entirely prevented any waggon or other passing load from striking against the column. The traffic had been running for nearly a year, and Mr. Cottrell, the Company's engineer and manager, had told him only yesterday that there had not been any sign of settlement, as far as he was aware, throughout the whole length. The great point was in such a case to permit of only very moderate pressure upon the foundations. He wished to say a word about the parapet. He did not know that it was very beautiful, but it had proved efficient. It was necessary that the parapet should be so arranged as to enable people to get out and walk to a station without danger if the train should stop outside; for otherwise the Board of Trade would probably have required special provisions. There was a parapet which practically gave a station platform along the whole length of the line, and at each span there was an ample refuge for the platelayers. The parapet was very cheap and free from rattle. It fulfilled an unexpected use, as had been mentioned; namely, that for a considerable length it had been used for the purposes of carrying compressed air. Another very important point in all railways of that kind was to have sufficient stations; in fact, the perfect ideal would be to have a station of the whole length of the line. That could not be quite accomplished. The complaint the people made in Liverpool—he did not know whether they were any worse than the people in London—was, that they did not like to go by the railway, because when they alighted, they had to walk 100 yards to their destinations, and that was their reason for travelling by omnibuses! To minimise that objection as far as possible, 13 stations had been already constructed, and it was intended, in the six miles, to have no less than 17 stations. He would like to say one other thing: It was not necessary, because there were a number of stations, to spend a great deal of money upon them. He thought that some success had been obtained in giving a fairly æsthetic appearance to the stations, and that at a very moderate cost. The outlay per station, including staircases, roofing, two platforms, turnstiles and everything complete, had averaged about £2,000, which could not be called excessive. There were no complicated or difficult engineering works on the line; it was more a matter of great detail, involving, he might mention, over 1,000 detail drawings, apart from the working plans. There were two or three matters in which he must specially admit the indebtedness of the engineers to Mr. Hudleston, One was the Stanley swing bridge, which was really a clever design for that particular position. It was not a large swing bridge, but it was a peculiar one. It had two levels, and had to be arranged in a very restricted space, so that it could be fixed with a minimum interference with the existing traffic. The bridge was so arranged that it not only could swing as a whole but was also a bascule bridge so far as the lower or dock lines portion is concerned. The lower half could be raised to allow barges with masts to pass underneath without interfering with the traffic on the overhead railway.

Mr. Alfred Giles (President) asked if any way-leave was paid for the line.

Sir Douglas Fox replied that there was a rental paid to the Dock Board under agreement. He wished to point out that the superstructure of the railway was strongly braced longitudinally by the introduction of cluster piers at intervals, and that the curvature of the line was overcome by the introduction of triangular piers, so that all the spans, even on the curves, were rectangular. One point with reference to the tilting bridges, of which there were two or three, was that they were so designed as to have all the appearance of ordinary spans; and, being in connection with the hydraulic power available on the dock estate, they were moved in the simplest possible way. The permanent way had proved highly efficient, although it was light and economical. One great advantage was its being kept strictly to gauge without difficulty by means of chubs, which were solidly riveted on the platform. The Timmis automatic electrical signals were working satisfactorily, after certain improvements in detail had been introduced to prevent residual magnetism, short circuiting, and certain mechanical defects. The principal magnets, which worked the signals, give a pull of 34lb. at a distance of $1\frac{3}{4}$in., with 10 amperes. The Board of Trade inspection of the railway occupied four days, there being over 500 spans on the open portion, each of which, of course, had to receive careful examination. Those four days of testing gave a very interesting result incidentally, in reference to the handiness of electricity for the quick stopping and starting of trains. It had been found that the trains were thoroughly under control, and the work of testing could be carried on far more rapidly than he had ever known with ordinary locomotives. The test-load for the ordinary structure was four loaded trains, each weighted so as to be equal to a train with a full complement of passengers, and with the motor-bogies placed together in each train, instead of at the ends as in ordinary working. With this load, which amounted to about 13cwt. per foot of each line of way on a 50ft. span, the deflections were very small. On a 40ft. span they were $\frac{1}{8}$in., and on a 75ft. span they were $\frac{1}{2}$in. On the Stanley Bridge, which from its depth would be expected to be very stiff, the load was far more severe. There, four of the heaviest Lancashire and Yorkshire tank-engines, weighing about 30cwt. per foot run, were placed on each low-level line of way, in addition to the loading of the overhead line with 13cwt. per foot run, making altogether about 4 tons per foot run of bridge, and the deflection was about $\frac{3}{8}$in. at the nose of the bridge. It might be interesting to state what considerations had chiefly guided the engineers in deciding the question of motive-power for the railway. If locomotives were to be used, certainly the cost of the superstructure must have been increased. They could not have had anything like the same moderate rolling-load or such efficient starting and stopping as with the electrical arrangement. Locomotives would also have required much more expensive coal, which, with the water, would have greatly added to the weight of the trains. A more fatal objection, however, was this—that the Dock Board would not even allow smoking on its estate, and they were not likely to tolerate locomotive engines emitting sparks, which were much more dangerous to adjoining property than those connected with the electrical motors. For that reason alone it was decided that locomotives could not be used. They had carefully considered the question of the introduction of the cable system; but, of course, this was not a case in which that motive power would work out with any great advantage, because there were no steep gradients, except one little dip of 1 in 40 down and up again. With that exception, the line was practically level. When it was considered that the cable must be kept constantly running, involving a much greater loss of power than arose from the leakage of electric current, and that, in addition, they could not get anything like the speed between the stations that was obtained by means of electricity, they arrived rapidly at a decision to give the preference to the latter medium. He had found from recent careful investigations in the United States, that it did not prove economical to run a cable at a higher speed than 12 miles per hour, which would not give an average, including stoppages at stations, of more than six miles per hour, or about one-half the speed attained on this railway. The incessant noise caused by the cable was also a serious objection. He wished to confirm distinctly what had been said by Sir W. Forwood, the Chairman of the Company, that they were more than satisfied with the result. There was great punctuality of the train service, and he was glad to know that Mr. Cottrell was present, and no doubt would give the latest figures with regard to the cost of haulage on the line. One thing was certain—that it had been possible, by the introduction of electricity and of short trains, to give a most efficient local service. One great point in a line of that kind was to be able to run trains of a moderate length at very short intervals, rather than heavy and long trains at much longer intervals; and he could not help thinking that some of the metropolitan railways would obtain greater success if they were to adopt that plan. Even waiting three or four minutes at a station seemed a long time; whereas if very short trains were run that interval might be considerably shortened. He agreed with Mr. Greathead as to the advantage in this case of adopting motor cars, although under other circumstances, and especially where long and heavy main-line trains had to be dealt with, separate motors might be necessary. An advantage of having two motor-cars, each having one motor, in the train, was that, like twin screws in a steamer, in case of injury to one the other is available to drive the train, although, of course, at reduced speed. The total cost of the works, stations, and equipment was £90,100 per mile. The general works, comprising the whole of the foundations, superstructure and permanent way cost £59,000 per mile. The stations had cost £4,600 per mile. The electric plant, including the conductor and the generating station, cost about £7,700 per mile. The rolling stock, including carriages and motors, cost £5,000 per mile. The accommodation works, which were quite outside the general question of a railway of that kind, and represented chiefly the cost of altering the dock lines and roads underneath, cost £13,800 per mile. In addition to these costs, there was the outlay of £4,400 per mile for the Act of Parliament, administration and other matters, making a total expenditure of £94,500 per mile. He thought that the Liverpool Overhead Railway was a successful solution of the problem Mr. Greathead and he had been asked to solve—viz., to provide for running short trains at rapid intervals, and at a low rate of cost. He hoped that this railway, which he thought bid

Digitized by Google

fair to prove not only a mechanical and electrical, but also a financial success, might be the forerunner of greater things; and that the time might shortly come when not only trains of 40 tons weight would be dealt with, but also on main lines—especially tunnel lines—trains weighing 200 tons would be worked by electricity. He had no doubt that this, to secure which active effort was now being made, would come to pass in the near future; and that the considerable step in advance which had been secured at Liverpool would tend at any rate towards that important result.

Mr. Killingworth Hedges considered the assertion that electrical railways were suitable for level ground, or districts with comparatively low gradients, and were not suitable for steep gradients, was not altogether correct. He might refer to Canadian practice, where there were already nearly 300 miles of electrical railway. The Niagara Falls Electrical Railway, a line about 11½ miles in length, from Chippewa, above the falls, to Queenstown on the Niagara River, afforded an illustration of his statement—and many of those who had heard Prof. G. Forbes' Paper on the scheme for utilising the Niagara Falls on the American side, would be pleased to know that, whilst the Americans had been talking about what they were going to do with that immense power, the Canadians had on a very small scale actually handled the power, and since July, 1893, had utilised it for this railway. It ran along the road for part of the distance and was carried on an embankment like an ordinary railway until it reached a steep descent to the Niagara river, where the gradient was 1 in 21, and in some places, he had been informed, 1 in 19. Having had facilities to inspect the line, he had found there was not the slightest difficulty in working this electric railway up those gradients. The ordinary 30-foot American cars were used, with two motors, and as very often there was great stress of traffic, because the Niagara Falls and the surrounding country was essentially a holiday place, a trailing car was put on. One interesting point about the railway was that the whole of it was Canadian, even the rails having been rolled in Canada. The power was taken from the rapids above the Falls, a flume ran for a short distance into the power-house, where two turbines were fixed 60ft. down in the solid rock. From the outlet, water was taken by a tunnel which opened under the Falls, so that the water mingled with that of the Falls, and was no detriment to the beauty of the scenery. With regard to cost, having travelled through the United States, and having seen a great many figures with regard to different electric railways and tramways, he must say, in compliment to the authors, that he could not find any case where the working expenses were as low as those given in the Paper. He had received a communication from Mr. Robert Gillham—a well-known American expert in cable tramways—giving the working expenses of an elevated electrical road in Kansas City. It much resembled the Liverpool Overhead Railway, except that it was rather longer—20 miles, including the surface lines. The cost per train-mile for ten months ending January, 1894, came out, according to Mr. Gillham, at 12·9 cents, say 6½d., per train-mile. Coal cost $1. 75c. per ton of 2,000lb., or 7s. The working cost of the Denver City cable line for the last quarter was 14 cents, or 7d. per train-mile, the mileage being about the same. The train on the cable-line consisted of a dummy car with a gripper and a trailing car; in the other case it was only one car. The number of passengers carried was approximately the same. He would ask the authors if they could give any comparative cost of installation of cable lines and electric railways. There appeared to be a great desire to employ cable lines throughout England, arising partly, he believed, through want of confidence in electric railways, and partly because of the overhead system. If gentlemen who had to do with municipal affairs would take a trip to America they would see the latter railways working well under every condition; and, with regard to unsightliness, he thought the superior advantages of electricity would be found to amply compensate for any drawback of that nature.

Mr. A. P. Trotter said that it had been observed that in the Liverpool line the head-room was restricted; but the electric features were not so restricted, and it was on account of the head-room that the engineers had been enabled to put the conductors above the level of the rails, instead of being obliged to place them below that level, as in the City and South London line, where their arrangement had led to great complication in the crossings. Three-quarters of an inch only, he understood, was sufficient to clear the conductor above the level of the rails. A feature of the Liverpool line, which surely would be of very great importance when electric traction became more common, particularly in light railways, was placing the motors upon the carriages and doing away with the locomotive. Head-room, again, was, he understood, the reason why locomotives were used on the City and South London, and why motors on the carriages were considered to be impracticable. A still more important reason for having motors on the carriages was that a number of motors could be used. In this case there were only two carriages; but with a greater number the multiplication of motors was easy, and brought with it very great economy. It was not generally known that Dr. John Hopkinson had a patent for the combination of electric motors in series or parallel. That patent had not been maintained, but it was interesting to know that the period would expire in July, 1895. It was strange that on the City and South London Railway that system had not been adopted, but it was employed on the Liverpool railway. The placing of motors in series and in parallel was a very great improvement in the economy of current in starting. The starting of a motor might be compared very accurately with the starting of an inward-flow turbine. When an inward-flow turbine was started, the whole head was unnecessary for the work of starting the turbine. The requisite momentum of the water could be obtained by much less head; but when the turbine got up speed, the centrifugal force checked the water, and finally the turbine worked at full load. Similarly with the electric motor, when

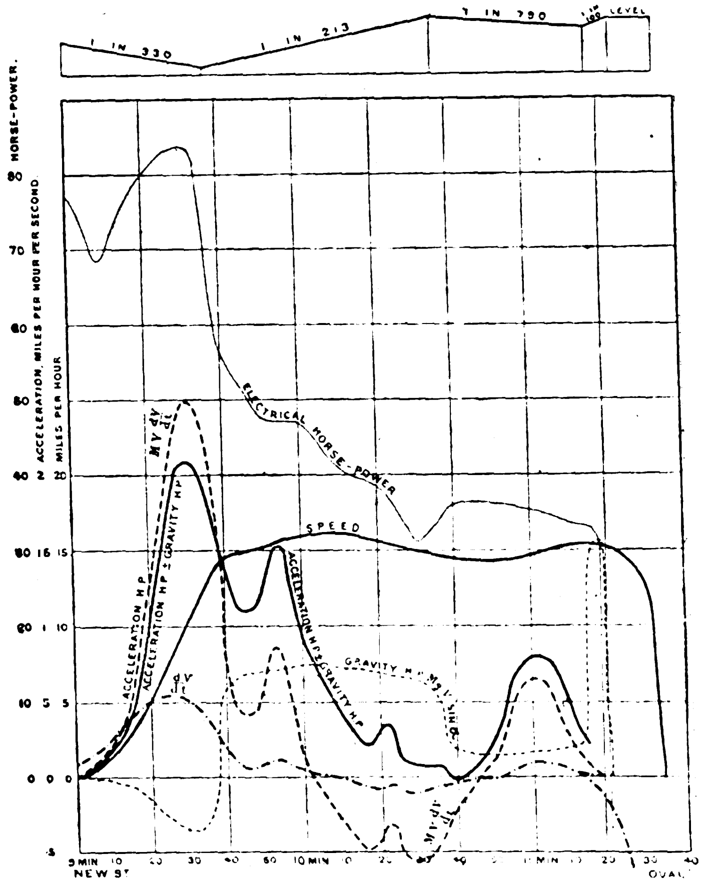

Fig. 1.—Analysis of part of Fig. 3, Minutes of Proceedings Inst. C.E., Vol. CXII., p. 246.

The full lines, marked Electrical Horse-power and Speed, are reproductions of curves in Fig. 3, Minutes of Proceedings Inst. C.E., Vol. CXII., p. 246.

The chain-dotted line marked $\frac{dV}{dt}$ is the slope or differential coefficient of the speed curve, and gives the positive or negative acceleration.

The strong dotted line is the continued product of the acceleration of the speed at any instant, and of the mass (35 tons); and gives the acceleration horse-power, *i.e.*, the horse-power required to set in motion at the given speed, on a level line, a frictionless train of 35 tons.

The fine dotted line gives the gravity horse-power; that is, the power expended in lifting, without friction, a mass of 35 tons, or the power developed by the falling of this mass, and is the product of the weight into the speed into the sine of the gradient. The transition from one gradient to the next being unknown, and the length of the train being neglected, the corners have been so rounded as to give a smooth resultant in the line of total calculated horse-power.

The full line marked Acceleration H.P. ± Gravity H P. is the resultant total calculated mechanical horse-power, exclusive of friction. It is not carried to the end of the run, as the instant at which the brake was put on is not known.

The gradients are shown on a time scale, corresponding with the scale at the foot of the diagram.

the speed was low the current simply ran away to waste, and at last was checked when the motor got up speed by the back-pressure generated in the motor, not unlike the centrifugal force in the turbine. He directed attention to some diagrams, Figs. 1 and 2, in which he had analysed carefully the theoretical power required for a specimen case on the City and South London line, the diagram of which had been furnished by Mr. Greathead, with a view of discovering the portion of power expended in starting, in climbing gradients, in pure traction and in friction. Before the train had

Digitized by Google

attained a speed of 10 miles an hour, a very serious amount of energy, amounting to about 18 per cent., had been lost by current running to waste through the motors.

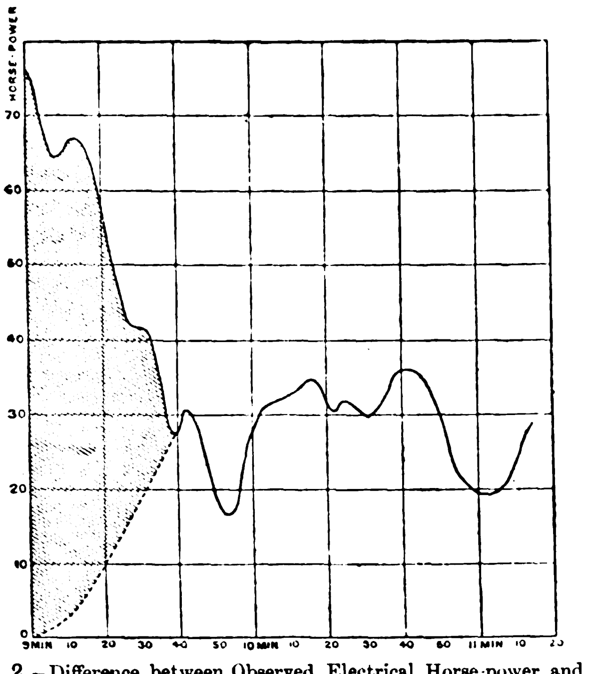

FIG. 2.—Difference between Observed Electrical Horse-power and Calculated Mechanical Horse-power, which equals the power expended in Traction and in General Friction.

The dotted line shows assumed power, proportional to speed, and therefore in excess of actual power.

The shaded area represents the energy wasted in starting the train, which is, to a large extent, avoidable.

Mr. W. H. PREECE had, like many other members of the Institution, spent his holidays last year in the United States during the months of August and September, devoting special attention to the working of the telegraphs and telephones of America, and also looking carefully into the questions of electric lighting, transmission of power, and other practical applications of electricity. Nine years had elapsed between his two visits to the States. In the year 1884 there was only one electrical railway there, and that in its experimental stage, viz., in the city of Cleveland. Last year he had found in the city of Cleveland a greater mileage of electric railway than there was in the whole of the United Kingdom. Throughout the States there were no less than 6,000 miles of railway worked by electricity. There were 6,900 motor cars, and 4,000 trolley-cars working in conjunction with the motor-cars. At the Chicago Exhibition there was a track laid down for the special purpose of testing and examining all the exhibits which were shown, and he had had the pleasure of spending some hours with the electrical jury testing and examining a locomotive that weighed 30 tons. This locomotive was said to exert a pull of 6,000lb. on the draw-bar, not a very marked result, but still sufficient to draw a train of 500 tons weight along a level English railway. More than that, in the city of Baltimore there was an electric locomotive weighing no less than 80 tons, intended to draw trains weighing 1,200 tons through that city. The peculiar feature of the electric railways of the States was that up to the present time they had rather replaced horse-tramways than really introduced what were known as railways in this country ; and, owing to the difficulty of climate, the cost of horse-flesh, and the short duration of its life, electric tramways had proved economical and very successful. They had proved a great financial success, for, owing to the smoothness with which the trains ran, they had greatly increased the comfort of travelling, although they ran between the same points and on the same rails. This comfort of travelling by the electric trains had increased the traffic 30 per cent., so that, for no other reason whatever than the introduction of electricity, they had introduced what the Americans called, in their practical way, a "factor of public satisfaction." The practical feature in which members would be perhaps more interested, was that the trains were almost all worked by wires overhead, on what was called the trolley system. That system, on a small scale, had been introduced in Leeds, and also in the Staffordshire district, in the neighbourhood of Walsall ; but its development in England was small compared with that in the United States. There it was seen not only in all the suburbs of the cities, but also in the great cities themselves ; and anything more horrible had never been seen in this world than those wires extending through a beautiful city like Boston, simply covering the principal thoroughfare with a cobweb of a diameter of about $\frac{1}{8}$in. to $\frac{1}{4}$in. The great problem now being solved in the States was how to work those railways by an underground system, and how to get rid of the disturbances arising through the use of the earth. That problem had been solved at Washington and Chicago, and probably in a year or two someone would come forward to give the results of those experiments. The only railway in the States which would compare with the magnificent railway described by the authors was one that extended through the midst of the World's Fair at Chicago, called the Intramural Railway ; and to give an idea of the extent and size of the Exhibition, that railway, which had been constructed simply to carry visitors round and about the various buildings, was $3\frac{1}{4}$ miles in extent. It worked extremely well. It was very like the Liverpool Overhead Railway ; it had a third rail, not in the centre, but by its side, and the rails were used for the return. Twelve trains were constantly running without accident or trouble, and it was a comfort to be thus able to move about from place to place in the Great Fair by that charming railway. Another feature worth noting in the United States was that experience had shown that they had commenced with too light rails in the early days, rails of about 30lb. to 35lb. weight per yard having been thought satisfactory. These had been gradually increased The Intramural Railway had been constructed with rails weighing 60lb. per yard ; several lines had been constructed with 72lb. rails, and he was told there were one or two railways where they had even gone to the extent of using rails weighing 90lb. per yard ; finding that, by using those heavy rails, the cars ran more smoothly, and there were none of those jars and jolts and discomforts that interfered so much with the working of motors and electrical appliances. Again, the Americans were fast following the English example of direct-driving in their power-houses. He found one single fault, and only one, and that perhaps a personal one, in the system adopted in connection with the Liverpool Railway, viz., that the general practice in this country of using direct-driven machinery had been abandoned for the use of rope-driven apparatus, which he thought was a slight survival of the past. In the States many power-houses were found where rope-driven machinery was the rule ; but, on the other hand, in all modern stations and all new work, the system which had been found so much better in England, of using direct-driven machinery, was being adopted. He thought, on the whole, after a most careful examination of what had been done in the States, that the authors had unquestionably taken a great step in advance at Liverpool. That was nothing in the States that was superior to, and he did not know anything that was as good as, the working of the railway described. One feature referred to in the first Paper deserved to be brought strongly under notice, viz., in Table B, it was shown from experience that the tractive-force in pounds per ton of motor or locomotive was, for the electrical system in the Liverpool Overhead Railway, 730lb. per ton, and on the City and South London Railway, 367lb. per ton ; so that, in the short period between the construction of the two lines, the same engineer, by the advance which had been made in electricity, had been able to increase the tractive force nearly 100 per cent. Going to the Metropolitan District Railway, it was found that the tractive force per ton of the locomotives was only 234lb. ; so that the difference between the traction per ton on the District Railway and that on the Liverpool Overhead Railway was the difference between 234lb. and 730lb. That was an advance of which English engineers might be very proud. The most important feature brought out in the Paper was the economy of electrical traction. He had more than once pointed out in that room that the economy of electric traction and the production of electrical energy was entirely dependent on the ability to maintain a full and constant load. Whenever a revolutionary doctrine was enunciated, even though it might be the truth, it was always received with ridicule by those whose interests were effected ; and when he asserted, as he had done in that hall, that, if he had the means of producing electrical energy constantly and continuously at a full load for 24 hours, electric light could be produced at a price equivalent to gas at 2d. per 1,000 cubic feet, he had been laughed to scorn. The engineers of the Overhead Railway had shown that, although they had not a load continuous for 24 hours, they had one continuous for nearly 12 hours, and the diagram showed that the mean load throughout the day was fairly constant. The author of the second Paper had shown that the cost of working that line was 4d. per train mile, and hence the cost of production of electrical energy to maintain the traffic on the railway was equivalent to $\frac{5}{10}$d. per mile, and $\frac{5}{10}$d. per mile was not far short of gas at 5d. per 1,000 cubic feet ; that was, if the energy used for working the trains were used for generating light. The results of the experiments on the Overhead Railway showed that the figures he had given were approximately true, and also that the secret of working electrical appliances, whether for light, for traction, or any other purpose, was to maintain continuously as long as possible a full load, and to maintain the machinery at its maximum working. The fact had been mentioned that the leakage on

Digitized by Google

the railway at Liverpool was a mere 2 or 3 amperes, and that such an unnecessary refinement as using oil to reduce this was absurd. There was a marked amount of selfishness about that. It might be perfectly true that the Liverpool Railway could afford to lose 2 amperes or 3 amperes; but there were persons in Liverpool, and interested persons, who could not admit that the absorption by the earth of 2 or 3 amperes was a refinement. The Postmaster-General did not like to find, as was found, that every single circuit in Liverpool was disturbed by the elevated railway. It was perfectly true that he was very good-natured, and they had not applied to the Court of Queen's Bench to obtain an injunction to stop this railway; but if its managers allowed the 2 or 3 amperes to become 20 or 30 amperes, it might be they would find some day an application by the Postmaster-General to the Lord Chief Justice to stop the traffic on that railway. But it was not alone the Postmaster-General who had an interest in stopping the leakage, for how about the gas people?—how about the water people? One of the most striking features brought to his notice in the States was the terrible havoc committed amongst gas-pipes, which were riddled and pitted all over, and water-pipes which were corroded and destroyed, whilst the lead coverings of the telephones cables were absolutely a decayed mass through this refinement, or absence of refinement—not a leakage of 2 or 3 amperes, as at Liverpool, but a leakage amounting to 200 or 300 amperes. If those gentlemen did not look after the pennies, they might depend upon it the pounds would bring them into very serious difficulties. There were several problems that were unsolved. It might be taken as a fact that where there was great diversity in practice, perfection had not been attained, and there was great diversity of practice in electrical railways. It was not yet determined which was the best mode to work electric railways, whether by alternating currents at low frequency, or by the continuous current as at Liverpool and in the City and South London and Chicago railways. Again, practical men who had to look to pounds, shillings, and pence, were not satisfied with the means at present developed in starting trains. With a steam locomotive a train was started without loss of energy, but on an electric railway, the train was started with a considerable loss of energy, and the great waste of energy occurred at the moment the train was starting. Someone would have to produce a remedy, and he was sure that if Mr. Thomas Parker devoted his attention to it he would introduce some means by which to start the electric train without any useless loss of energy. The Americans, he was proud to say, paid great heed to what was being done in this country. They thought, no doubt, we were a grandmotherly lot, and were very slow; but they all admitted that we had adopted a thoroughness and a refinement in our methods that it was necessary for them to follow. Doubtless the Paper now brought forward would be read and studied in America with great interest. Sir Douglas Fox had stated that the Dock Board were so particular about fires that they would not allow a man to smoke. Quite right; a bad practice! But they would not also allow locomotives, because they emitted sparks, and therefore electric traction was introduced. Mr. Preece did not know whether Sir Douglas Fox laboured under the illusion that electrical machinery could always be worked without producing sparks. One of his amusements in the States was to watch the electrical railway at night, for a more beautiful display of fireworks he had rarely seen. If Sir Douglas Fox was satisfied with the absence of sparks on the Liverpool Railway, then something or other must have been done on that railway which had not been described in the Paper. He hoped that when Mr. Parker replied he would give some explanation as to how sparks were stopped in Liverpool. The authors had said that the Americans in New York studied very carefully the application of electricity to elevated railways, and had given facts and figures showing that the cost of applying machinery to the Elevated Railway was estimated at £771,000. The authors had, however, shown that the cost of the plant on the Liverpool Railway of the same length and character was only £45,000, or only 5 per cent. of the estimated cost of the Elevated Railway in New York. Again, the engineers at New York made out the cost of working the Elevated Railway to be 3s. per train-mile, but now the fact was on paper that not only was tractive power greater than that produced by steam obtained, but a magnificent railway was worked in first-rate style, giving satisfaction to everybody, at the small rate of 4d. per train-mile.

(To be continued.)

The Field Telegraph.—The field telegraph, says *The Times* keenly critical correspondent who has been exposing the various shortcomings of Aldershot in 1894, has been occasionally used to maintain connection between bodies of troops operating in combination but at some distance apart, and has proved a complete success.

"UNIQUE" SWITCHES.

The latest improvements in these switches are shown in the accompanying illustrations. They are now made in four sizes, up to 20-ampere capacity. Mr. Lundberg, the manufacturer, informs us that the helical bronze springs used are now uniformly tempered. In the smallest size of switch the key is of special construction, and persons, whether wilfully or ignorantly turning the key against the springs, can do no mischief through buckling them, the key undoing but not detaching a rubber ring, taking all strain against the roof of the cover. The brass work of the key is fixed to it by an improved method which has superseded the use of tapped porcelain, the latter method, though perfect in theory, having proved very unsatisfactory in practice, the screws invariably shaking loose.

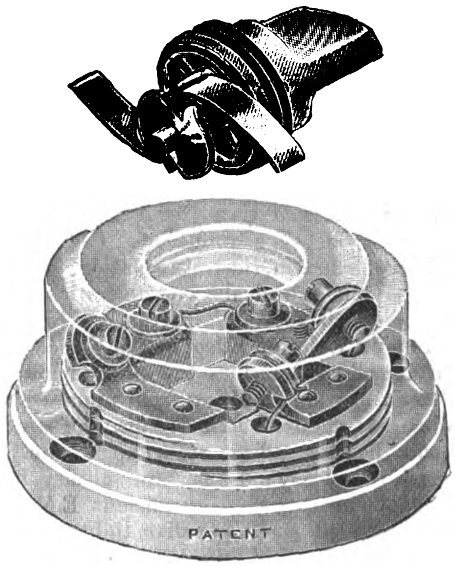

Fig. 1.—Improved "Unique" Switch.

The brass cradle piece, to which the springs are attached, is now made out of stampings only, the spring being clamped between lugs attached to the two parts forming the complete cradle, in this manner the split pins previously used for this purpose are done away with.

The bases of all sizes are still arranged for use as single-way switches with or without fuse, or as two-way switches for corridor or bedroom lighting, for operation at either end, with or without fuse as desired.

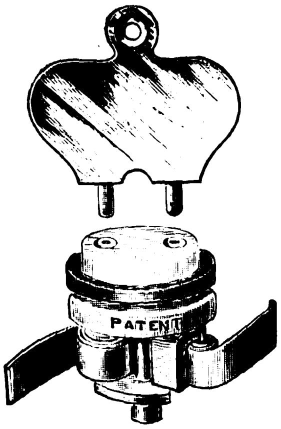

Fig. 2.—Porcelain centre with key.

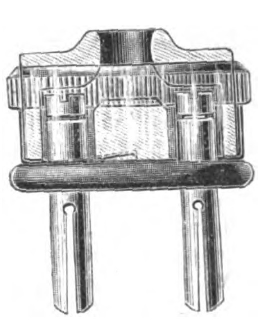

Fig. 3.—Ratchet plug.

Improved terminals are also used in all sizes, the method adopted in the smallest size being shown in Fig. 1, the leading wires being drawn into the slot of the lug on the contact plate, and clamped under the screw, the slot preventing it slipping out and allowing the wire practically a full turn under the screw.

In the larger sizes use is made of a screw-eye terminal, the leading wires passing through the screw eye, and being clamped against the upright lug of the contact plate through which the screw-eye passes, by means of a hollow nut. The 3-ampere and 6-ampere sizes can be fitted, if desired, with porcelain centres for use with removable keys (*see* Fig. 2) at the same price as ordinary keys.

Digitized by Google

A 3-ampere damp and dust-proof pattern with brass cover is now on the market, and is intended for use in exposed positions. Fig. 3 shows an improved 2-pin ratchet plug for use in the "Unique" combination switch and wall-socket, which prevents any possibility of the springs being damaged if turned backwards, the spring tongue of the ratchet only engaging when turning to the right.

The illustration (Fig. 3) fully shows the construction and operation of the plug, which is supplied at a slightly increased cost over the ordinary fixed pattern.

We have had a number of Unique switches in daily use for nearly three years, and have found them to work and wear well. One or two springs have broken, either from imperfect tempering or from attempts to turn the handle the wrong way. We have had two Unique wall plugs in use for the same period, but find it necessary to pull out the plug and to untwist the cord at intervals to take out the kinks. The ratchet plug described above does not seem to get over this difficulty, but Mr. Lundberg's ingenuity ought to be able to surmount it.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 25, 1894.

The American Association for the Advancement of Science.—Among the very numerous Papers read at the recent meeting of the American Association for the Advancement of Science but few dealt with electrical subjects, and none of these were of special importance. In the Paper by Prof. Sheldon on "A Calorific Effect of the Velocity of Vibration of Hydrogen Ions," he describes the phenomena of the "pail forge," or electric heating resulting from plunging a metal in a liquid forming part of an electric circuit, and stated that the theory of this heating effect rests upon the inability of hydrogen ions to travel beyond a certain velocity, which results in the heating of the cathode, if sufficient E.M.F. is applied. Prof. M'Adie described some peculiar lightning flashes, and stated that, in order to obtain accurate knowledge about lightning discharges, it is necessary to have two or more photographs taken from different points of view; for this purpose Prof. M'Adie has three cameras pointed at the summit of the Washington monument in the city of Washington, one at the Capitol, 1·4 miles distant; a second at Fort Myer, four miles distant; and a third at the Weather Bureau, 1·3 miles distant. Mr. C. J. Roffelson described a method of producing the alternating current curve by the aid of the phonograph, for which two operations are necessary; first a record on the wax cylinder of the phonagraph, and, second, magnifying this record by means of a multiplying arrangement. It is stated that this method is especially adapted for the study of harmonics. Prof. Brakett described some magnetic characteristics of iridium. It was found that a bar of this metal is more readily magnetised transversely than longitudinally; that the magnetic intensity, compared to that of steel, is as 1 to 12; that position or movement in the magnetic field is not sufficient to magnetise it, jarring being also necessary. Low permeability and great coercive force are the characteristics of this material. Mr. N. D. C. Hodges presented a Paper on "Lightning as a Case of the Dissipation of Energy," in which he stated that, while he does not know how much energy it takes to deflagrate a pound of copper, he does know that no lightning discharge has ever manifested enough energy to deflagrate more than two or three pounds, and he thought, therefore, that there might be a foot pound of energy in a cubic foot of electrified air. The empirical nature of Mr. Hodge's statements was severely criticised by Prof. Alex. Macfarlane. A mathematical Paper by Mr. L. A. Bauer was read, the title being "The Extension of the Gaussian Potential Theory of Terrestrial Magnetism," in which it was shown that it is theoretically possible to calculate the potential of terrestrial magnetic force at the earth's surface, thus enabling a secular variation term to be introduced into the Gaussian potential expression, and an expression therefore obtained which would permit the drawing of approximate magnetic charts for any time during the interval for which the formula had been established. By this means the orbit described by the magnetic pole in the course of centuries could be determined, but the statement is made that the practicability of this determination is doubtful at present on account of the lack of data. Prof. B. W. Snow, in a Paper on "The Directed Velocity of the Particles in the Electric Arc," described the details of a spectral method of investigating this subject, the result of which showed that the direct velocity of the particles in the arc is less than one mile per second, and, therefore, that the temperature of the arc cannot be calculated from the directed velocity of the particles.

Engineering Education.—During the meeting of the Association, the Society for the Promotion of Engineering Education held its meetings, and a large number of Papers were read and presented. Owing to the small amount of time available, but few of the papers were read in full, and these but little discussed, In the discussion on the subject of graduate and post-graduate degrees, a consensus of opinion was developed to the effect that the old academic degrees are not of much use to the engineer, who seems to prefer to replace them with the abbreviaton of his professional society. The Society for the Promotion of Engineering Education was organised at the World's Fair, where the first meeting was participated in by the professors in attendance on the various scientific congresses there being held. Much interest is being taken in the Society by the various professors of engineering in the United States, and it promises to take high rank among professional societies. Its main object is to produce some order out of the chaos of opinions now held in this country in regard to the policies and methods of engineering education.

CORRESPONDENCE.

THE SINE-CURVE CONTROVERSY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I only lately became repossessed of my weekly copy of *The Electrician*, and read the letters and editorials on the above subject. Broadly speaking, all the evidence I have before me, deduced from a very extensive series of tests on transformers, which have been made on different types of alternators grouped in various ways, leads to a conclusion which is identical with the position taken up by Mr. Steinmetz. If one and the same transformer is tested at the same mean-square primary pressure of an alternator of different types, the iron loss in the transformer at no load is found to vary. Taking, for instance, a particular type of transformer, I found that when tested for iron loss on an alternator having a drum armature, with iron core of the type of Westinghouse or Thomson-Houston, the iron loss is less by some 10 per cent. than when tested on an alternator having a copper strip iron-less armature of the type of the Mordey or Ferranti armatures.

It must, however, be borne in mind that the form of the electromotive force curve of an alternator, when determined by an electrostatic voltmeter and contact breaker—the alternator being taken alone and on open circuit—is not necessarily or always identical with the form of the curve of potential difference between the primary terminals of a transformer worked off that alternator. It is, of course, the form of this last curve which it is important to know. I find, also, that the power factor of a transformer at no load is less when the transformer is tested at the same mean-square primary pressure off an iron-clad or iron-cored armature of the drum type, than when tested off a strip iron-less armature; but that the apparent power taken up in both cases is about the same. Coming, then, to one question at issue, viz., the form of electro-motive force curve, which the alternator should possess in order that the iron losses of transformers worked off it should be a minimum. This is a question which can only be settled by an experimental comparison of the no-load losses of transformers tested off alternators of which the E.M.F. curve is at the same time ascertained. In order to do this when the alternator is at a distant place, some means must be obtained of driving a revolving contact breaker at a definite speed relatively to the alternator. This, I find can be done by putting the contact breaker on the shaft of a small synchronising alternate current motor, which runs in step with the distant alternator, and enables the instantaneous curve of potential difference between the primary mains to be ascertained. By the employment of this device I expect to be

Digitized by Google

able to place against one another the results of a series of tests in which the iron losses of the transformer are compared with the form of the curves of the primary potential difference applied to its terminals. Until these experiments are complete it is impossible to state positively that the E.M.F. sine curve is the best or the worst form for minimising the iron core losses of transformers. Up to the present it has certainly not been shown that it is the best.—Yours, &c., J. A. Fleming.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Your remarks regarding the efforts of some American manufacturers to produce alternators giving true sine waves are quite apposite and to the point at the present time, and the views to which you give expression probably accord quite as well with the real views of American manufacturers generally, as do those you venture to criticise. Manufacturers generally in America are, I believe, very little concerned regarding the form of wave given by the alternators they make, and very much indeed with the development and construction of alternators of high efficiency that are mechanically strong in which the ratio output-weight is great, the expense of construction moderate, and that are capable of operating circuited apparatus with the highest attainable efficiency. On being able to make and to use machines meeting these requirements depends in a great measure the financial success of the manufacturer, and of those engaged in the business of alternating current supply.

It is found in practice that alternators having armatures of the so called "iron-clad" or overhanging projection type, meet requirements so satisfactorily that they have almost entirely superseded those having armatures of the old smooth-core type, and thus in a great measure effected the retirement of sine waves. These "iron-clad" armatures are vastly better from a mechanical standpoint than the old smooth-core armatures. The wires are well protected in the slots and efficiently driven. The possible output also is 60 to 75 per cent. greater, but, generally speaking, they do not give anything resembling sine waves; nevertheless, their substitution for the old type has not resulted in any decrease in the efficiency (*i.e.*, increased core losses, &c.) shown by apparatus operated upon the circuits which they supply; indeed, so far as I have been able to find, facts point the other way, and indicate the possibility of securing higher efficiencies (*i.e.*, decreased core losses, &c.) by the use of alternators giving waves of comparatively irregular form. Some of the earliest constructed of these "iron-clad" alternators reduced the core losses of apparatus circuited with them 12 to 15 per cent. below the value found when the same apparatus was circuited with smooth-core machines giving practically sine waves. This is a matter of record, and probably two years old.

Of course, in particular transmissions, when the use of alternators giving sine waves appears desirable, they will be met as special cases and so treated.

A possible explanation of the advertisements regarding alternators that give true sine curves, to which you refer, occurs to me. It is well known that some kinds of measuring and metering instruments vary in some way in their indications, with variations in the form of wave in the circuit. For example, a manufacturing company making a meter of this kind, and having a large number in use, that have been calibrated and run on circuits supplied by old style smooth-core armature machines, might in a manner be compelled to maintain the integrity of meters in use by getting as nearly as possible the same form of wave from "iron-clad" armatures. The vigilance of some trade rivals might readily result in the appearance of advertisements of alternators giving "true sine waves." Some time they may, perhaps, warrant them not to give sine waves. It may be noted that the great armature reactions occurring in the modern type of alternator make the wave form change with the armature current; I do not know how nearly such machines, if made to give sine waves—say, when running without load—would maintain the wave form when fully loaded.

In conclusion, I will say that until direct experimental evidence is forthcoming that is much more conclusive toward establishing the reality of the general advantages claimed for sine wave alternators than has yet been produced, an impartial jury must, for the present, find a verdict of not provens and dismiss the case.—Yours, &c. R. Shand.

Lynn, Mass., August 27, 1894.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

Tenders Invited.—Tenders are invited by the General Direction of the French Posts and Telegraphs, 103, Rue de Grenelle, Paris, for the supply of 10,000 galvanised iron crosspieces for telegraph poles. Tenders have to be in by the 20th inst.

——— The Directors of the Great Western Railway require tenders for the supply of a variety of stores, including telegraph instruments, telegraph apparatus, copper wire, telegraph ironwork and tools, telegraph drysalteries, electric light carbons, indiarubber goods, telegraph poles, and yellow pine, &c., &c. Particulars can be obtained at the office of the Stores Superintendent at either Swindon or Paddington Station; and tenders must be sent in by Monday, the 8th prox.

——— The Glasgow Corporation invite tenders for the construction of about half-a-mile of double line of tramway. Tenders have to be sent in to the Town Clerk by the 18th inst.

——— The Electrical Committee of the Bristol Corporation invite tenders for the construction of transformer chambers in certain streets in the Clifton district. Plans, &c., can be obtained of Mr. H. Faraday Proctor, the city electrical engineer, and tenders must be sent in by noon of the 18th inst.

——— The Directors of the London, Tilbury, and Southend Railway Company require tenders for a quantity of stores, for which information can be obtained at the Secretary's office, Fenchurch-street Terminus, London, E.C. Tenders must be in by the 17th inst.

Tenders Received.—The Works Committee of the Dundee Gas Commission have received tenders from Henley's Company and the Silvertown Company for the supply of electric cables for the police office buildings, and these tenders have been referred to Messrs. Urquhart and Small for their report. The cost is expected to be about £325.

Bankruptcies.—A receiving order was issued on September 7th against W. David Gooch, electrical engineer, of 2, Willes-road, Kentish Town (late of 3, Victoria-mansions, Westminster, S.W.).

——— A receiving order, dated September 3rd, has been issued against H. W. Young, O. Buss, and C. W. W. Young, trading as Young and Buss, wholesale ironmongers and electric bell manufacturers, 18, Blandford-street, and 8, Blenheim-street, W. The first meeting in this matter takes place at the Bankruptcy Court, Carey-street, W.C., on the 20th inst., at 11 o'clock, and the examination of the bankrupts on October 30th, at 12:30, at the Bankruptcy Court.

——— Notice is given that the adjourned meeting of creditors in the matter of Arthur Shippey, a bankrupt, will be held on the 17th inst., at Bankruptcy-buildings, Carey-street, W.C., at half-past two o'clock.

Queen and Co. (Philadelphia).—The creditors of Queen and Co. (who have recently suspended) have decided to grant the firm an extension of three years in the hope of thus obtaining a settlement of their claims in full. If at any time during that period the business shows an actual loss the creditors reserve power to cancel this extension agreement and to have a receiver appointed to wind up the Company's affairs. The course above referred to was suggested by the management. The debts are about $200,000 with bills receivable and book accounts of about $80,000.

New Premises.—Messrs. Laurence, Scott and Co. have just opened new premises in Regent-street, Norwich, where they have fitted up a model electric lighting display, and have on show a variety of electroliers and electrical apparatus for all purposes.

Velvo-Carbon.—The Battery and Motor Company send us reports and particulars of tests of the velvo-carbons. These reports and tests have been made by Mr. Andrew Jamieson and Mr. H. T. Barnett. Accompanying the tests are several current and potential diagrams.

Elmore Copper.—It is stated that the tests made by Government departments upon Elmore copper have proved sufficiently satisfactory to warrant the War Department to place the Elmore Patent Copper Depositing Company (Limited) on the list of contractors to the Department.

Digitized by Google

Street Fire Alarms.—Mr. Kennedy, the Magistrate at Greenwich Police Court, has this week severely punished a stupid man named Metcalf for interfering with the street fire alarm posts. At two o'clock in the morning Metcalf broke the glass and pulled the bell communicating with the fire brigade, with the result that at this early hour in the morning firemen, fire-engines, and life-saving ladders were turned out on a purposeless errand. It is satisfactory to know that the culprit has been mulct in the heavy penalty of £20, with the alternative of a month's imprisonment. The Magistrate, in giving his decision, stated his intention of severely punishing any person brought before him charged with a similar offence.

Picture Reflectors.—The registered picture reflectors made by Messrs. B. Verity and Sons, and for which that firm claim many advantages, are being fitted throughout the new picture gallery belonging to the Oldham Corporation.

Eighty Kilowatt "Sayers" Dynamo Machine.—For an extensive electric lighting contract which they have in progress in Russia, Messrs. Mavor and Coulson, of Glasgow, have just finished a dynamo constructed on the "Sayers" principle, which is understood to be the largest electric generator yet made in Scotland. Its working capacity is said to be equal to 1,350 16-c.p. lights. The dynamo is to be coupled direct to a Belliss engine of 120 i.h.p., with which it is being tested this week at Birmingham. Interest attaches to this dynamo from the fact that it is stated to be not more than half the weight of any machine of other types whose generating capacity is the same. As may be remembered by those members of the Institution of Electrical Engineers who heard Mr. Sayers's Paper read, and the interesting discussion to which it gave rise, or who may have since read the Paper, the saving in the weight of the machine depends on the novel character of the armature winding which is used in its construction. The dynamo is to be used in a large textile factory in Russia, where there have already been installed upwards of 3,000 lights. Messrs. Mavor and Coulson have supplied all the other plant for the installation, which has been carried out on the concentric system of wiring.

Private Telephones.—The new offices of the *Daily Chronicle* in Salisbury-square, E.C., have been fitted throughout with a telephonic installation by the Private Wire and Telephone Installation Company on the inter-communication system, by which the various rooms throughout the building are enabled to have immediate and direct communication with each other, while dispensing with the central switchboard. The instruments used are magnetos, which are fitted with Hunnings transmitters. The building has also been fitted throughout with electric bells by the same firm.

Electro-Harmonic Society.—The first smoking concert of the season takes place on Friday, the 28th inst., at the St. James's Hall Restaurant, Regent-street, W., at 8 o'clock. An excellent entertainment will be provided, the *artistes* including the Westminster Singers, Messrs. Walter Coward, Harper Kearton, Charles Ackerman, W. H. Brereton, and James Kift. Mr. Leo Taussig is the violoncello, Mr. A. Izard, solo pianist; and the musical direction will, as usual, be under the able directorship of Messrs. T. E. Gatehouse and A. Izard.

Insurance Companies' Accounts.—Those interested in the elaborate accounts issued by the insurance companies may obtain in handy form "The Insurance File," which contains reproductions in reduced fac-simile of the annual reports and balance-sheets of the principal insurance offices in the United Kingdom. The third annual issue of this useful publication is now published, and can be obtained, price 1s., of the Editor, 21, Godliman-street, E.C. In addition to the actual accounts issued by the companies, a chapter is added dealing with the various schemes of life insurance, for which the companies claim special advantages.

Battersea Polytechnic.—The day classes for technical and science subjects open on Monday next, and the evening classes on the evening of Monday week. The instruction in these subjects is associated with laboratory or workshop work. The institute possesses laboratories for chemistry, mechanics, physics, and electrical science, and workshops for engineers, carpenters, plumbers, &c.

Bedford.—A resolution was carried at the last meeting of the Rural Sanitary Authority that the Corn Exchange, Town Hall, and Town Hall offices be wired ready for the electric light the ensuing winter. Tenders are to be invited by the Public Buildings Committee for the work in connection with the electric lighting of the buildings.

Birkenhead.—At the last meeting of the Town Council the plan prepared by Mr. J. N. Shoolbred for the proposed central electric light station was approved, and the Town Clerk was instructed to submit the same to the Local Government Board for their approval in connection with the application for sanction to borrow £20,000 for electric lighting purposes.

Birmingham.—The work in connection with the electric light at the Market Hall is now nearly complete, and the lighting will be effected in about a fortnight. Gas has been burned most unscientifically in this building, and although it has only been used about 15 hours per week, it is now costing at the rate of £522 per annum. From experiments made it has been proved that electric lighting will be found more economical from the 23 arc lights used—16 of 15 amperes and 7 of 10 amperes. Current will be taken from the Birmingham Electric Supply Company's mains in Bell-street. The installation has been designed by Messrs. Lea and Thornbery, and carried out under their supervision by the Walsall Electrical Company. Brockie-Pell arc lamps are used, and the ornamental ironwork has been supplied by Messrs. Hart, Son, and Peard. The electric light is shortly to be introduced into the new meat market, the municipal schools, and the botanical gardens.

Blackburn.—The electric lighting at the Art Gallery and Free Library has proved very successful, and credit is given on all hands to Mr. Walter Leake, the consulting electrical engineer, under whose supervision the work has been carried out.

Bradford.—At the meeting of the County Council, on Tuesday, Mr. Alderman Moulson presented the accounts of the electricity department, which showed that £4,964 had been received for the sale of current, the total receipts being £5,418 against £4,547 for the corresponding half of last year. The gross profit for the half-year was £2,189, against £2,294 for the corresponding half of last year.

Broughty Ferry.—A special meeting of the Police Commission has been held to consider what steps should be taken with regard to the proposed electric lighting of the burgh. In the course of the discussion on the subject a Mr. Lamond was bold enough to inform his fellow members that the electric lighting system had been a gigantic failure at Dundee, and, further, that many of the shopkeepers in that town would be only too glad to get rid of the electric light if they could. That this statement is contrary to the fact is amply proved by Messrs. James Maxwell and Son, who are responsible for a large portion of the private lighting in Dundee. This firm point out that not one of the 200 consumers of electric current in Dundee has asked to be disconnected from the Corporation mains; but that, on the contrary, many of them have extended their original installations. The fact, however, that Mr. Lamond had mis-stated the position in Dundee does not appear to trouble him. He is of opinion that, if the Broughty Ferry authorities allow the Northern Electric Supply Company to obtain the Provisional Order they are applying for, the Police Commission will be able to buy them out on their own terms in a very short time, although even this comforting possibility failed to reconcile him to the project. A motion pledging the Council to neutrality in the matter of the Northern Company's application, on condition that gas be used for the motive power at the generating station, and that this gas be taken from the Council's works, was persevered with. But even this conciliatory attitude was more than Mr. Lamond could entertain; he therefore proposed that a meeting of the ratepayers should be called before a copper was spent on electric lighting, and this view ultimately found favour with the members of the Council.

Burton.—In the discussion of the report of the Gas and Electric Light Committee of the Town Council, Councillor Rugg asked if there was not an enormous waste of electricity when the engines were running in the evening and, if so, whether the Committee could not recommend the purchase of accumulators in which to store the electricity, so that it could be used in public places, and for electrical fans, and for ventilating public buildings. The Council's gas manager replied that there was no waste of electric current.

Church Lighting.—The lighting of the new Catholic church at Norwich, to which reference was made in our last issue, consists of 80 25 c.p. incandescents for the nave, 40 in the aisles, four in the main entrance, and 46 of 16 c.p. in the presbytery. All the brackets and lamp-holders are of aluminium. The whole of the work, which is very effective, has been carried out by Messrs. Laurence Scott and Co., of Gothic Works, Norwich.

Club Lighting.—The Garrick Club, London, W., is now illuminated throughout by the electric light. The effect of the light is described as charming, and the artistic treasures, with which the walls of the building are crowded, can now be inspected as easily by night as by day. It has hitherto been necessary to guard these treasures against the ravages of gas, and many of the members will now be able to view their precious belongings for the first time under the genial influence of the electric light.

Country House Lighting.—Altyre House, the seat of Sir William and Lady Gordon-Cumming, has just been improved at a cost of nearly £15,000, the improvements including a complete system of electric lighting throughout the mansion.

Coventry.—It is stated that the hitch respecting the construction of the proposed electric tramways is likely to be overcome, the Board of Trade having agreed to the diversion of the line on the Warwick road, provided certain conditions are carried out by the contractors. It is proposed to proceed with the work as an unauthorised undertaking, for which Parliamentary powers will be obtained in the next session of Parliament.

Digitized by Google

DERRY.—In reference to complaints which have been made as to the extinguishing of many of the public lamps, a report was presented to the Corporation by Mr. Christie, the resident electrical engineer, stating that these faults were not at all attributable to himself or his staff. A letter was read at the last meeting of the Corporation from Messrs. Siemens Brothers and Co., declining to admit that the failures in the cable were due to defective manufacture, or to careless handling on the part of their men, but stating that they would consider the question of defraying the expense to which the Corporation had been put for the reopening of the streets to reach the defective parts of the cable. Messrs. Siemens Brothers and Co.'s responsibility for the working of the cable is in force until May 29, 1895. Mr. Blake, the electrical engineer to the Corporation, had been in consultation with Dr. J. Hopkinson, the consulting electrical engineer, whose opinion on the subject had not yet been received. After a long discussion the Council adopted Mr. Christie's report. The Lighting Committee have paid the local Gas Light Company £450 for the 670 gas lamps which it is proposed to utilise in the supply of electric current to the portion of the city not yet lighted electrically.

DEVONPORT.—The Town Council have received intimations from the Brush Provincial Company and Great Western Electric Light and Power Company of their intention to apply for Provisional Orders to supply the Devonport district with electric current. The matter has been referred to the Streets Committee.

EALING.—*The Times* is responsible for the statement that in connection with the electrical exhibition which is to be held at Ealing to celebrate the introduction of the electric light on Wednesday, the 3rd prox., and following days, "almost every known system of telegraphic and telephonic manufacture and manipulation will be shown." As the main object of the exhibition is to introduce to the Ealing public apparatus connected with electric lighting, cooking, and heating, visitors will be more concerned to learn that the exhibition has met with the co-operation of several leading electrical firms, who will display their special manufactures of lighting, cooking, and heating apparatus. In addition, there is to be a loan exhibition, and practical illustrations of the application of electricity to a variety of domestic purposes. Sir Frederick Bramwell will lecture on "Elementary Electricity," and Mr. W. Lynd on "Edison and his Inventions."

EDINBURGH.—The Electric Lighting Committee of the Town Council have agreed to recommend that a deputation be sent to Westminster, London, for the purpose of examining the electric lamps used in that district for lighting the streets, similar lamps being about to be introduced in the lighting of Edinburgh thoroughfares. The price of gas has been reduced from 3s. 6d. to 3s. 2d. per thousand, and so here, as elsewhere, the electric light proves of direct benefit to the ratepayers.

ELECTRIC LIGHT AND POWER IN NEWSPAPER OFFICES.—The *Sheffield Telegraph* has for some years past used the electric light in its printing and editorial offices, and electric power has been used for the printing machines. The success of the installation has been clearly proved, and the proprietors have just decided to duplicate their electric light and power plant, which at present consists of a Tyne dynamo for use during the day, and a Wilson-Hartnell 500-light dynamo for night use. The duplicate plant will consist of a Willans compound engine, coupled to a Wilson-Hartnell 500 16-c p. light dynamo.

FAREHAM.—A Board of Trade inquiry has been held by Major Cardew, of the Local Government Board, in respect to the proposed transfer of the local Electric Light Company's undertaking to the Municipal Authorities. Considerable opposition to the proposed transfer was made by Mr. Smith and several parties whom Mr. Blake (representing the Electric Light Company) described as the friends or shareholders of the local Gas Company—a family party. Mr. Blake stated that the Electric Lighting Company had brought about a reduction of 9d. per thousand in gas, and had so materially benefitted the ratepayers. Mr. Abraham, a member of the Local Board, said the reason the Board entertained the proposed purchase was that the townspeople had expressed their satisfaction with the light, but had been somewhat misled as to the cost. Major Cardew will shortly issue his report.

GATESHEAD.—A sub-committee appointed by the Town Improvement Committee of the Corporation have had before them a report from the Town Surveyor on the electric lighting question, and it is expected that the Committee's report on the subject will be discussed at the next meeting of the Corporation.

GLASGOW.—As mentioned in our last issue, a report has been issued by the Committee on Gas Supply and Electric Lighting of the Glasgow Town Council. The report embraces the period from June 1, 1893, to May 31st last. The electric lighting accounts show a gross revenue of £18,016, with an expenditure of £9,592, to which is added the depreciation written off capital of £4,393, the balance carried to profit and loss being £4,031. As set off against this balance, interest on loans and the sinking fund represent £4,638, leaving a deficiency on the year's operations of £607. The report states that this deficiency is due to the cost of public lighting, the rate having been fixed at too low a figure to be remunerative. The result, however, of the year's working compares favourably with its predecessor, the deficiency for 1893 being £1,174. The improvement arises from the fact that the Waterloo-street station has been fully employed, the revenue having increased from £7,784 to £18,016, and the expenditure not having increased in the same ratio. The Committee anticipate that this improvement will not only be maintained, but that the use of electricity will be further developed during the coming year, in which anticipation they are confirmed by the numerous applications for current which have been received since the beginning of the year. To meet this increasing demand, the Committee have resolved to lay down at the Waterloo-street Station additional plant. The number of consumers from the Corporation mains at May 31st last was 378, or an increase of 270 over the number at the same date last year. 543,178 units of electric current have been sold during the past year to private consumers alone, and this represents an increase over the preceding fifteen months of 107·14 per cent. The balance-sheet accompanying the report shows that, of the amount of £200,000 for which the Corporation have borrowing powers, £120,000 has been borrowed at 3¼ per cent., and of this amount £116,585 has been expended, leaving a balance in hand of £3,415. A statement accompanying the report gives the following figures:—

Year ending May 31.	Quantity generated. B.T. units.	Total quantity sold. B.T. units.	Quantity used on works. B.T. units.	Total quantity accounted for. B.T. units.	Quantity not accounted for. B.T. units.	No. of public lamps.	Per cent.	Total maximum supply demanded Amperes.
1893	408,529	287,712	13,975	301,687	106,842	26·15	71	7,900
1894	854,766	702,248	13,326	715,574	139,192	16·28	102	16,839

The Tramway Committee's report announced that the weekly receipts showed satisfactory increases. All matters in connection with the transfer of the tramways from the Tramway Company to the Corporation have been satisfactorily negotiated. The Committee had arranged for the cars being illuminated by the electric light, and this would be carried out in a short time. Two lamps were to be provided for the inside and two for the outside, the latter with special regard to sufficient light being provided to enable passengers to read with ease and comfort.

HERTFORD.—The public meeting convened by the Town Council for the purpose of discussing the electric lighting question was held last week. It was pointed out by the Chairman, Mr. A. Hawks, that the Town Council had obtained a Provisional Order, and they must take action in the matter, or they would lose it. A discussion followed the Chairman's remarks, in which Mr. G. A. Munnings, who admitted himself a large shareholder in the local gas company, proposed a resolution that it was undesirable to proceed with the electric lighting scheme. Mr. Munnings was followed by several gentlemen opposing the scheme, including a Mr. Burton, who hazarded the statement that the electric light "could not be satisfactory, or it would be adopted in the British metropolis." Several speakers, in more moderate language, gave the scheme their general support. The electric light would improve the appearance of the town, and show that it was imbued with a spirit of progress. An amendment was subsequently moved that the whole question should be left in the hands of the Town Council. Ultimately the original resolution was carried.

INFERIOR GAS.—The Gas Light and Coke Company were, on Monday last, summoned before Mr. Vaughan, at Bow-street, London, for supplying gas of less illuminating power than that specified under Acts of Parliament. The Company stated that they were quite unable to explain how the deficiency came about. The magistrate imposed a penalty of £25 in one case and 40s. in another, with 25s. costs.

LLANDUDNO.—The grounds connected with Mr. Riviere's Concert Hall are now successfully lighted by electricity. Brockie-Pell arcs are used. The work has been carried out by Mr. Kingsland.

LIGHTING THE HOUSES OF PARLIAMENT.—It is stated that during the present recess considerable further progress is to be made with the scheme of electric lighting at the Houses of Parliament. In consequence of the heavy expenditure entailed it was decided some time back to complete the installation by degrees. This has resulted in the lighting being complete in the lobby, in the Octagon hall, in the principal of the corridors, the main staircases, the dining and smoking rooms, the reporters' gallery, and the House of Lords. Several of the committee rooms have also been provided with incandescent lighting; but there still remains much to be done before the Houses are completely illuminated by electricity. It will possibly surprise many to learn that oil lamps are still used in some of the offices and committee rooms at Westminster, and that it is not an uncommon experience for a Committee to suspend its deliberations while oil lamps are prepared to counteract the effects of a suddenly-developed fog. The main

Digitized by Google

corridor of the Houses is still lighted by a few old-fashioned gas jets.

LUTON.—At the next meeting of the Town Council a motion will be discussed that the Highways and Lighting Committee consider and present a report on the question of applying for a Provisional Order for the supply of electricity for public and private purposes within the borough, and the probable cost of obtaining the order.

MIDDLESBOROUGH.—The Electric Lighting Sub-Committee of the Corporation, after inspecting the electric lighting system at Newcastle, Leeds, Blackpool, Huddersfield, and other large towns, have come to the conclusion that the electric light is a paying business, and that profit is made by its adoption. Consumers in all the places visited testified to the fact of the electric light being superior to gas, and said that they would on no account return to the latter method of lighting. The sanitary effects of electric lighting are in the right direction, and the saving to electric current consumers' goods represents a substantial figure. The Committee said they were particularly pleased with the installations at Blackpool, Huddersfield, and Leeds, and recommend the Middlesborough authorities to proceed forthwith with the laying down of an electrical installation at a cost not exceeding £25,000.

MIDLAND INSTITUTE.—A new organ has just been put in at the Midland Institute, Birmingham, by Messrs. Nicholson and Co., of Worcester, at a cost of about £1,200. The organ is supplied with a large French feeder driven by a Crompton motor. This electric blowing apparatus is self-regulating, and supplies wind power at a very small cost in fact, at much less cost than by any other method.

MILL LIGHTING.—It has been decided to light by electricity the extensive range of buildings forming the Draycott Roller Flour Mills, Cam, Gloucestershire, together with the private residence, workmen's cottages and stables connected therewith. The order for the work has been secured by Messrs. Knapman, Hodder and Co., of Cardiff. The motive power is supplied by a steam engine and a large turbine, and the electrical plant includes a battery of accumulators.

MONMOUTH.—The Town Council have appointed Mr. Lailey, C.E., to prepare plans and specifications for the combined scheme for drainage and electric lighting for the borough, the work in connection with which is to be entrusted to Messrs. Bramwell and Harris.

MONTROSE.—At a meeting of the Town Council, on Monday, Provost Mitchell moved that the Corporation should apply to Parliament for a Provisional Order to supply electric current within the Montrose district. This was met by a direct negative from Mr. Strachan, who expressed himself favourable to the introduction of electric lighting to the town; but contended that it would be better for one or other of the two companies which had intimated their intention to apply for a Provisional Order to do the work necessary in connection with introducing the light into the district. They had an offer from a private company to supply electric current 25 per cent. cheaper than gas. The amendment was carried by 11 votes to 5. Notice was given by Provost Mitchell that he should take an early opportunity of calling a public meeting to support him in offering the most strenuous opposition to the lighting of the town being put into the hands of a private company.

NELSON.—As the result of a deputation from the Tradesmen's Association a reduction has been made in meter charges, and discounts are now allowed on electric lighting accounts for prompt payment.

PORTSMOUTH.—At the meeting of the Portsmouth Chamber of Commerce complaint was made that the electric light mains interfered with the working of the telephone instruments, and it was the opinion of several members that during the coming winter, unless something was done, the use of the telephone would be lost for a considerable portion of the day. A sub-committee of the Chamber is to be appointed to deal with the subject.

RAILWAYS FOR SLOW TRAFFIC.—At the meeting of the Associated Chambers of Commerce at Huddersfield a motion was agreed to affirm a resolution passed unanimously at the general meeting of the Association at Newport in 1892, and again at Plymouth in 1893, calling upon the Council of the Association to bring under the notice of Government the importance of offering facilities for the authorisation (without special application to Parliament) of inexpensive lines of railway adapted for slow traffic to meet the requirements of thinly populated districts.

READING.—The new arcade in Friar-street is now open to the public, and of the 20 handsome shops 16 have been furnished with electric light by the Reading Electric Supply Company, the fittings being supplied by Messrs. Williams and Sons and J. W. Dew, of Carey-street. Six electroliers are used for lighting the central part of the arcade, and prove a great attraction. The County Court offices, forming a portion of the new block of buildings, are to be lighted throughout by electricity. The buildings are erected from designs by Mr. F. W. Albury.

REDDITCH.—Some discussion took place at the last meeting of the Local Board as to the erection of additional gas lamps in various portions of the district, but it was decided to let the matter remain in abeyance until the Committee appointed to consider the lighting of the town by electricity had presented their report.

SALISBURY.—At the last meeting of the Town Council it was stated that the new electric light central station works are to be finished by February next.

SOUTHAMPTON.—A busy scene was witnessed in the Empress Dock on Wednesday, when the hired troopship "Victoria" was prepared for her first trooping voyage. For this purpose the South-Western Railway Company set apart a quay opposite to that occupied by the American Liners, where a shed was specially built to provide accommodation for the military. The shed was supplied with the electric light, and this enabled work to be proceeded with at night with the same facility as in daylight.

STAFFORD.—The Electric Lighting Committee's report was presented to the Town Council at its last meeting and adopted. The report states that the work at the station is making satisfactory progress, and that six tenders had been sent in for the supply of cables upon which Dr. Hopkinson, the Corporation's consulting electrical engineer will shortly report.

STOCKTON.—The Board of Trade have agreed to defer the revocation of the Corporation's Electric Lighting Order for two years, on condition that the works are started within that period.

ST. GEORGE (BRISTOL).—The Local Board, at its last meeting, discussed the lighting question, and Mr. Essery pointed out that about £2,000 a year was spent in lighting the district, and he thought the time had come when St. George should be placed in the same favourable position with other parts of the Bristol district, and urged the introduction of the electric light. He was quite sure if they went into details they would find that the cost of lighting by electricity did not exceed that of lighting by gas. He did not recommend so ambitious a scheme as that undertaken by the Bristol authorities, but proposed that a £10,000 installation should be at once proceeded with. Money could be borrowed for 30 years at a low rate of interest. The proposal was accepted, and a committee was appointed to consider the subject, and report to the Local Board.

STREATHAM (LONDON, S.W.).—The "Greyhound," a well-known place of public resort, has been fitted throughout for the electric light by Mr. G. Stegmann. Eighty 16 c.p. incandescents are at present in use, and provision is made for 150 lights. The generating plant is on the premises, engine power being supplied by a 7 H.P. nominal Stockport gas engine.

TELEPHONE EXTENSION.—Skene and Echt have just been placed in telephonic communication with Aberdeen. The service was opened last week.

THEATRE LIGHTING.—The Theatre Royal, Brighton, which has been closed for nearly four months for reconstruction, the introduction of the electric light, refurnishing, &c., was opened last week. The electric light has been fitted throughout the theatre, 600 16 c.p. incandescents being used; 400 of these lamps are placed on the stage and its precincts. The electric lighting work has been carried out by Messrs. F. Geero Howard and E. S. Dashwood, of Berners-street, London, W., and under the personal superintendence of Mr. Dashwood. The stage will, it is stated, prove to be the best lighted theatre stage in England. The current is obtained from the Corporation mains.

TOWING BY ELECTRICITY.—It is stated that an electrical method has been adopted for towing the canal boats of the summit level of the Canal de Burgoyne, which connects the Seine and Saone, crossing in its course the divide between the Channel and the Mediterranean.

ULVERSTON.—The Local Board have communicated with the Board of Trade stating that, owing to the inhabitants showing no desire to embark in electric lighting enterprises, partly from the fact that great expense has been recently incurred in making provision for an efficient supply of gas, it is not the Board's intention to take any steps to introduce the electric light, and they ask the Board of Trade not to entertain any application from outside parties to supply electricity within the Board's district.

WARMINSTER.—The Committee appointed to consider the desirability of extending the electric light through the town have recommended the placing of additional arc lamps at a cost of £184. 10s., and a further expenditure of £50 on an additional dynamo. The Committee's recommendation was approved, and they were instructed to carry out the work.

WELLS (SOMERSET).—At the last meeting of the Town Council an application was made by Mr. Browne, of Shepton Mallet, asking for permission to supply electric current to the city for public and private purposes. Alderman Harte thought the application should not be entertained, because the ratepayers had from £20,000 to £30,000 invested in the gas works. A proposal that the matter be

Digitized by Google

referred to a special meeting of the Council, to be shortly held, was carried. It is stated that the majority of the members are in favour of a comprehensive electric lighting scheme.

WESTMORELAND.—The Windermere Electric Supply Company have announced their intention of applying for a Provisional Order to supply electric current within the district served by the Westmoreland County Council.

WHITEHAVEN.—The Town and Harbour Trust have discussed the report of their Electric Light Committee, in which a quotation from Messrs. Siemens Brothers and Co. for cable was recommended for acceptance. The Chairman, in presenting the report, stated that the applications for the electric light continued to come in "in almost too satisfactory a manner." The committee, therefore, recommended the trustees to apply to the Local Government Board for sanction to borrow further money for electric lighting purposes, and it was ultimately agreed that applications should be made for powers to borrow £6,304.

YARMOUTH.—The Electric Lighting Committee have presented their report to the Town Council, and recommend the discontinuance of the temporary installation after September 30th, until such time as the permanent plant shall be ready for lighting the borough. Along the line of the electric lamps which are to be ultimately put down there are about 120 gas lamps, which will not then be required. The Town Clerk has been instructed to give the gas company notice to this effect, as the gas lamps will be put out of use from November 1st.

YEADON.—At a meeting of the Local Board on Monday the electric lighting question was discussed. The Board have obtained a Provisional Order with the usual powers to manufacture and supply current for public and private purposes, and have obtained tenders for the construction of the necessary plant. The lowest of these tenders is somewhat higher than the estimate which was submitted to the ratepayers' meeting which sanctioned the Board's original scheme. Some of the members therefore proposed that the consideration of the subject should be deferred until after the elections in November, but ultimately it was decided to call in expert assistance to advise the Board on the tenders and the samples sent in.

COMPANIES' MEETINGS AND REPORTS.

Electric Construction Company (Limited).

The first annual general meeting of the shareholders in this Company was held yesterday (Thursday) at the Cannon-street Hotel, under the presidency of Sir Daniel Cooper, Bart., G.C.M.G.

The SECRETARY (Mr. James Gray) read the notice convening the meeting.

The CHAIRMAN said: Gentlemen, before you can form a sound opinion on the accounts which the Directors have the pleasure of submitting to you, it is necessary that I should briefly give you some idea of the troubles and difficulties the Directors have had to deal with and overcome in the past year. As you are aware, the old Company was successfully reconstructed last year; but, besides the work of reconstruction, the Board and the Managing Director had to deal with several entanglements that had to be taken over as a legacy from the old Corporation. These matters have been dealt with, and, if not completely straightened out, are now in a comparatively narrow compass. In the end of December the heads of three important departments at Bushbury resigned on one month's notice, without any intelligible cause, and would not be induced to stay a short time longer till their places could be conveniently filled by others. At the same time Mr. Parker, the Works Director, intimated to the Board that he would not renew his engagement, which was to expire in the coming May. The Board had no desire to retain him as Works Director, but they were willing to keep up his connection with the Company, and offered him a very liberal retaining fee as consulting engineer. This Mr. Parker declined to accept. About this time rumours became very prevalent that rival works were about to be built at Wolverhampton, but Mr. Parker strenuously denied that he had anything to do with them. Under these circumstances immediate steps had to be taken to reorganise the establishment, and in April it was found expedient to anticipate the termination of Mr. Parker's engagement by dispensing with his services. Now that the staff has been reorganised, the Board are not sorry that the changes have been made, because they have secured a chief engineer and a technical staff at Bushbury in whose ability and loyalty they have full confidence; but you will understand that such extensive changes could not be made without seriously interrupting the work in hand and the continuous flow of new orders, and that these explanations were necessary before you could come to a just conclusion respecting the accounts submitted to you.

I will now deal briefly with the accounts, which I am happy to think do not seem to require much explanation. And first, as respects the profit and loss account, I cannot say that I am satisfied, although it is quite as good as could be expected under the circumstances already explained. A good deal owing to depression in business, but perhaps more to the reasons to which I have referred, the profits at Bushbury are too small and the general expenses too large. I hope we shall be able to show you next year an improvement in both respects. The item of profit—£15,764. 10s.—on sales of shares and debentures of other companies requires some explanation. If you will refer to the balance-sheet you will observe an asset under the head of shares and debentures of other companies—£147,872 6s. 7d. These interests in other companies were valued by the Directors, when taken over from the old Company, according to the best of their judgment. They had great difficulty in arriving at what they considered a fair valuation, because none of the securities had market quotations. After much deliberation the prices fixed were such as were considered safe, but at the same time they could not then have been realised in the market. The values depended on the development of the undertakings. As it happened, the interests in certain of these properties matured more quickly than was anticipated, and the Directors found an opportunity of realising them before the end of the financial year, with a profit of £15,764. 10s.; this profit, less a proportion for general expenses, it is proposed to apply in reducing the amount at debit of this account, which will thus be strengthened by £12,500 to meet any unfavourable realisations, should such arise. Beyond the account—shares and debentures of other companies—I do not think there is any other item in the balance-sheet requiring explanation, but I shall be ready to answer any inquiries for further information. During the past year there has been extreme depression in business generally, and very keen competition in electric manufactures; but, as you see from the report and accounts, we can fairly say that we have held our own.

As to the future. I believe we have at Bushbury the finest electric works in the kingdom, and they are situated in a locality where work can be executed quite as economically as anywhere. Mr. Blackburn, the recently appointed Chief Engineer at Bushbury, has had wide experience in all kinds of electrical engineering, and is supported by a technical staff and a body of artisans at least equal to any other in the United Kingdom. All are determined to maintain the high character of the work hitherto turned out by our establishment, and we believe this can be done with greater economy than heretofore. The future, of course, depends to a large extent on the business activity, not only in this, but in other countries which we supply with our manufactures. All I can say is, we expect to obtain a fair share of what work is going, and to carry it out with reasonable profit to the shareholders. The business was never in so stable a position as it is to-day, and I do not think there is any cause to be apprehensive of the future.

Before moving the formal resolution I may add that a moderate increase of capital would be of advantage to the Company. There remains of the £100,000 Preference capital £74,010 unissued. The rate of dividend—7 per cent.—we think too high, considering the improved position in which the Company now stands, but there are various difficulties in the way of reducing the rate. A quotation on the Stock Exchange for the Preference shares has been obtained, and as we cannot redeem the portion issued, it would probably be impracticable to obtain another quotation for a new issue at a lower figure. The Directors have come to no conclusion on the subject, but it is probable that they may resolve to offer the balance of the present Preferred shares to the shareholders, giving ample time to pay up the calls, and thus the existing shareholders would receive, as they are well entitled to, the benefit of the high dividend payable on these Preference shares. I now formally beg to move—"That the accounts and report, with the recommendations therein contained, now submitted by the Directors, be approved and adopted."

Mr. J. W. BARCLAY: In rising to second the motion I have only to add, on behalf of the Directors, an expression of our great confidence in our present staff at Bushbury, and in the body of skilled workmen and artisans the Company have now in their service there. You are all aware how much the success of such a Company as this depends on the loyalty, the capacity, and the goodwill, not only of the staff, but also of the workmen engaged in carrying on the business. Amidst the competition which is going on now-a-days co-operation is necessary, and it is a matter of great satisfaction to the Board to think that they have now a staff of men and a body of officers in whom they have full confidence—not only as regards their loyalty, but also their capability for carrying out the work entrusted to them. On the other hand, I think that I may say the Directors have very much at heart a desire to enlist the confidence of the workmen, and, so far as lies in their power, they will be very anxious to take such measures in the interest of the staff and the workmen as will show them clearly that the Board are not merely a Board sitting here in London, but also a body of gentlemen who are really interested in the welfare of their employés. I now beg to second the motion.

Mr. WILLIAMS inquired why the travelling expenses—£1,463—had been so heavy; and he also thought that the item of postages and stationery—£910—was also very large.

Dr. DRYSDALE asked whether Mr. Parker had taken up with the other works alluded to by the Chairman?

Mr. COOKE said he wished to know whether Mr. Parker was starting a rival Company, and, if so, how this was likely to affect their Company through its being in want of capital, as the Chairman had stated. It seemed from the balance-sheet as if there was any amount of capital in the concern, although on the other side of the statement it appeared as if most of it was lost. He also saw that there was a contingent liability on certain of the shares held by them under the heading of "Shares and debentures of other companies." He supposed that the Chairman would not care to state what this liability was. They only had £8,753 cash in hand; and with "sundry debtors" amounting to £32,700, they would probably find themselves in an unpleasant position if calls were made.

Mr. HANCOCK regarded the report as very dispiriting. He considered that the handing over to the Electrical Power Storage Company of their electrical storage was somewhat scandalous. In explanation of that, he believed they received an assurance from the Chairman that their Company would have from that Company alone a dividend of £9,000 a year. He found, however, from the profit and loss account that the interest and dividends received by them on debentures and shares held by

Digitized by Google

them in all the other companies amounted to only £5,680, and he thought that this amount ought to be larger than £9,000, seeing that £9,000 was to be the minimum. The accounts also rather pointed to a not very satisfactory future for them. Only £3,000 was written off for depreciation, and he supposed that this depreciation referred to the item of £300,000 under the heading of "Properties, Patents, and Goodwill." Some of the patents, however, must be fast running out, while others must be very nearly run out. He thought, for instance, that the patent for the electrical storage battery must be very near to an end. A sum of £3,000 written off against £300,000 was, he considered, very small, and it would either have to be very largely increased in the future or else some day they would come to a dead loss which would have to be written off. He thought they had sustained a great loss by the termination of Mr. Parker's services. A leading feature in the prospectus of their Company was the great value that Mr. Parker's services would be to them. From time to time they had been assured that the greater portion of their profits had been derived from Mr. Parker's labours and inventions.

The CHAIRMAN: No, that was never stated.

Mr. HANCOCK, continuing, said that he had it in print, and that the statement had been repeatedly made. The various undertakings carried out by them—for instance, the Liverpool Overhead Railway Company—had been most skilfully executed, mainly by Mr. Parker. The Directors might have their own views as to the loyalty of Mr. Parker, but as regarded that gentleman's ability he considered that their Company had sustained an immense loss in losing his services. It would involve, he held, much stricter attention to economy in the working of the concern if they were to look for profits in the future. About £360,000 had been written off their capital; and, taking the difference between the par value of the shares at present—£2—and their existing market value, this loss was increased to about £500,000.

The CHAIRMAN stated that this loss had not been made in any way by the present Company.

Mr. HANCOCK, resuming, expressed his opinion that the cause of much of this loss was owing to the fact that the Board had been drawn from two sources—Mr. Spencer Balfour and his allies and Mr. Irving Courtenay and his allies in other companies. He considered that the Directors of such a company ought to be drawn from a larger area, and from outside sources, as new ideas would thus be brought into the concern instead of its being continually carried on in the same groove. He did not agree with the Directors' recommendation in the report that the vacancy at the Board should not be filled up. He held that one or two or more Directors should be elected on the Board, and that they should be drawn from an independent source, but connected with the same kind of business. Probably, it was a matter of figures, but it was stated that there were to be 14,620 Preference shares, whereas in the balance-sheet now before them there was a deficiency of 1,625 (or £3,250) in this number.

The CHAIRMAN, in reply, said: We have an executive committee, and we meet daily when necessary. We are always at work and always watching over the interests of the Company. Mr. Barclay takes charge of that, and you could not have a more efficient man to watch over your interests. With regard to the old Directors, the less you say about them the better. We are not answerable for what took place when you had 13 or 14 Directors. We have been clearing out all that coterie, and we have none of the allies referred to. When you talk about Mr. Irving Courtenay's allies, I am his only ally, and you can throw stones at me if you like. Mr. Irving Courtenay and I came on this Board together, and it was a bargain that we should do so.

A SHAREHOLDER stated that a net profit of £18,467 was shown on the past year's working, but this profit was reduced to £2,700 if they took away the profit made on the realisation of shares and debentures of other Companies.

The CHAIRMAN: I alluded to that in my speech. I said that the profit at Bushbury was not to our satisfaction.

Mr. BARCLAY, in further reply, pointed out that the Chairman had stated that the Directors considered that the travelling expenses and the postages and stationery were too high. Last year, however, there was a considerable amount of postage connected with the reconstruction of the Company. It must also be remembered that the Directors had only had one year's trial. They were appointed in the beginning of 1893. In June the Company was reconstructed, and until the present time they had hardly got settled down to the real work of the Company, what with the reorganisation of the staff, the reconstruction of the Company, &c. The Chairman had stated that it was hoped the general expenses would be much less next year. With respect to Mr. Parker, he though that all who were interested in electricity were aware that a prospectus was issued last April or May with Mr. Parker's name on it as consulting engineer; and the Company with which Mr. Parker was connected was now building electrical works at Wolverhampton. He did not exactly know the object of Mr. Hancock's depreciatory remarks, and he did not think it advantageous to *bonâ-fide* shareholders to refer to the old Company. The new Company had nothing to fear. Except as regarded this Company the present Directors were never connected with Mr. Balfour. With reference to the contingent liability on certain shares held by them, it would be misleading to mention it; and practically they did not estimate the liability as of very much importance. The Directors had carefully considered the question of depreciation, and they thought that if they maintained the works in their present condition, and wrote off £3,000 annually for depreciation, this provision would not be so very bad. If they carried this out they would have £30,000 in the course of ten years. This would be a neat sum to go to depreciation of the works, which would be fully maintained during the same period. As regarded what Mr. Hancock had said concerning Mr. Parker, he could only say that the Directors differed from him entirely. They had had twelve months' experience of Mr. Parker in various aspects, and whatever might be that gentleman's reputation in the engineering world, he thought that their Company had made a very satisfactory change in the management at Bushbury. That was all he felt called upon to say at the present time. As had been said, the profit at Bushbury was not satisfactory, and it could hardly be expected to be satisfactory under the circumstances, when the attention of the Managing Director and of the Directors had been so largely occupied in the reconstruction of the Company and, subsequently, in dealing with the reorganisation of the whole of the staff at Bushbury. There was an interregnum at the works, but the idea that they would be put into a corner there had not been realised. They hoped, under the new auspices, that they would now be able to show better returns; at any rate, with capable men and prudent management, he thought that they ought to show satisfactory results. He did not think that in the past two years very satisfactory results had been shown in the manufacturing world, and their Company was not in an exceptional position in this matter. He added, in reply to a further question, that no proceedings had been taken to restrain Mr. Parker from being connected with the other company referred to. The action which had been taken against Mr. Parker and Messrs. Parker and Co. (Limited) was with respect to a patent, and this matter was in abeyance. Messrs. Parker and Co. stated that the patent in question was its own, and this assertion was disputed by their Company.

The motion was then adopted, and resolutions were afterwards passed re-electing Sir D. Cooper to his seat at the Board and reappointing Messrs. J. Meston and Co. as auditors.

A vote of thanks to the Chairman and Directors terminated the proceedings.

Direct Spanish Telegraph Company (Limited).

The following report of the Directors of this Company for the half-year ended June 30th last is issued, and will be presented at the half-yearly general meeting of shareholders, to be held on Friday, the 21st inst., at the offices of the Company, Winchester House, E.C., at 12 o'clock:—

The accounts for the half-year show, after providing for debenture interest, a balance to the credit of profit and loss of £4,075. 15s. 10d. The traffic receipts show a decrease of £868. 12s. 9d. as compared with the corresponding period of 1893, this decrease being due to the continued stagnation of business in England, Spain, and France. The working expenses are £43. 4s. 1d less than those for the corresponding period of last year.

The Company's cables, and the land-lines in connection with them, have continued in good working order throughout the half-year. The construction of a new breakwater at Bilbao placed the Company under the necessity of moving the shore end of the Falmouth-Bilbao cable to a point outside the new breakwater further down the bay. The removal was effected without any appreciable interruption of communication, and the cost is chargeable to the Harbour authorities of Bilbao.

The £62,000 Six per Cent. Debentures, which matured on May 1, 1894, have been paid off, and £30,000 new debentures have been issued, bearing interest at the rate of 4½ per cent. The difference of £32,000 was provided for by making the final call of £1 per share on the 12,931 Ordinary shares, and by taking £19,069 from the reserve fund.

After adding the usual sum of £2,500 to the reserve fund, the balance of profit and loss amounts to £1,575. 15s. 10d. To this the Directors propose to add £951. 15s. 10d. from interest and profit on investments, and recommend the payment of the dividend at the rate of 10 per cent. per annum on the Preference shares, and a dividend, free of income-tax, of 1s. 8d. per share, being at the rate of 4 per cent. per annum on the capital paid up from the due date of payment, on the Ordinary shares of £5 each. The reserve fund will then amount to £21,270. 19s. 11d.

As the attendance of shareholders at the autumn general meetings is very small, and as the Articles of Association require only an annual meeting to be held, the Directors propose that in future only one general meeting shall be held—viz., in the month of March, but intend to pay an interim dividend in October, if earned.

NEW COMPANIES, STATUTORY RETURNS, &c.

COVENTRY ELECTRICAL ENGINEERING COMPANY (LIMITED).—This Company was registered on September 11th, with a capital of £5,000, in £1 shares, to acquire and take over as a going concern the business of electrical engineers and machinists now carried on at Ryley-street, Coventry, and to carry into effect an agreement, dated September 7th, between William H. Eaves, Frederick T. Jackson, William J. Butlin, and Eliza Eaves, and Ernest F. Peirson (as trustee for the Company), and to carry on the business of an electric light company, electricians, hydraulic, gas, electrical, pneumatic, mechanical, and general engineers, suppliers of electricity, manufacturers of electrical apparatus, wire drawers, metal tube manufacturers, iron and brass founders, metallurgists, machinists, &c. The subscribers, with one share each, are William H. Eaves, Frederick T. Jackson, William J. Butlin, Mrs. Eliza Eaves, Thomas H. Matterson, George F. Cowan, and Ernest F. Peirson. The first Directors are Thomas H. Matterson, Frederick T. Jackson, and William H. Eaves.

HAMPSTEAD GENERAL ELECTRIC FITTINGS COMPANY (LIMITED).—This Company was registered on September 6th, with a capital of £1,000, in £1 shares, to carry on the businesses of civil, mechanical, electrical and general engineers, &c., and suppliers of gas, water, electrical and other appliances. The subscribers, with one share each, are:—P. C. Gilchrist, Mrs. P. C. Gilchrist, W. W. Roff, William H. Roff, Oscar H. Stovell, R. H. Hoare, and G. Thomson. The first Directors are: Percy C. Gilchrist and Walter W. Roff. Mr. Percy C. Gilchrist may remain in office until death or resignation.

Digitized by Google

WILLIAM LANCASTER AND CO. (LIMITED.)—This Company was registered on September 3rd, with a capital of £25,000 in £10 shares, to acquire the business of a cotton mill and weaving shed machinery manufacturer at Moscow Mills, Oswaldtwistle, Lancaster, and to carry on the business of machinists, mechanical engineers, metal workers, tool makers, metallurgists, manufacturing chemists, electrical engineers, and suppliers of electric light, heat and motive power.

LIQUOR REGISTER SYNDICATE (LIMITED).—This Company was registered on September 7th, with a capital of £18,000, in £1 shares, to acquire, develop, and generally deal with inventions, letters patent, patent rights, &c., and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, and manufacturers of and dealers in mechanical and electrical appliances for registering the receipts of moneys and sales of goods. Among the signatories to the Memorandum of Association (each with one share) are :—C. W. S. Crawley, electrical engineer ; and C. F. Wilkins, electrician. The first Directors are :—Norman Tronson, Hugh E. Saunders, Charles W. S. Crawley, and one duly qualified person to be appointed by Messrs. Nalder Brothers and Co.

C. PASS AND SON (LIMITED).—This Company was registered on Aug. 31st with a capital of £100,000, divided into 5,000 Ordinary and 6,000 £6 per Cent. Cumulative Preference shares of £10 each, to carry on the business of smelters and refiners of metals, ores, &c., at Bedminster, Bristol.

SCIENTIFIC AND GENERAL ENTERPRISE SYNDICATE (LIMITED).—A Company has been registered under this title with a capital of £5,750, in 5,000 Preference shares of £1 each, and 15,000 Deferred shares of 1s. each. The object of the Company is to acquire and develop certain patents, which are not described.

SUBVENTIONED RAILWAYS CORPORATION (LIMITED).—This Company was registered on August 29th with a capital of £400,000 in £5 shares, to construct, equip, maintain and work public works of all kinds, including electric light, telephonic, telegraphic, and electric and general supply works.

FIELD'S M.P. DEVELOPMENT ASSOCIATION (LIMITED).—The annual return of this Company, made up to November 14, 1893, has been filed. The whole nominal capital of £100,000, in £1 shares, has been taken up, and 85,000 have been issued as fully paid. Upon the remaining 15,000 shares the full amount has been called, resulting in the payment of £14,530.

GLOBE TELEGRAPH AND TRUST COMPANY (LIMITED).—The annual return of this Company, made up to August 10th, has been filed. Out of a nominal capital of £5,000,000, divided into 250,000 Preference and a like number of Ordinary shares of £10 each, 180,042 Preference and 180,227 Ordinary shares have been subscribed for and allotted, the full amount called, and £3,602,690 paid.

HAMPSTEAD ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The undertaking of this Company has been abandoned, as they have failed to obtain the necessary Parliamentary powers.

MOSLEY AND COMPANY (LIMITED).—Owners of patents for depositing zinc by electricity upon steel, iron or any other metals. The statutory return of this Company, made up to June 30th, has just been filed. Out of a nominal capital of £11,000 in £1 shares, 6,657 has been taken up, and the full amount called, resulting in the total payment of £6,657.

NEW ELECTRICITY SUPPLY COMPANY OF CROYDON (LIMITED).—The statutory return of this Company, made up to January 24, 1893, was filed on June 26, 1894. The Company has a nominal capital of £40,000 divided into 100 Founders' and 7,900 Ordinary shares, all of £5 each, and of these 29 Founders' shares have been taken up and allotted.

ORIENTAL TELEPHONE AND ELECTRIC COMPANY (LIMITED).—The annual return of this Company, made up to July 18th, has been filed ; 171,497 shares of £1 each have been issued as fully paid to the shareholders in the old Company, and the signatories have subscribed and paid for one share each. The capital is £200,000, in £1 shares.

OTIS ELEVATOR COMPANY (LIMITED).—The annual return of this Company, made up to August 6th, has been filed ; 2,000 shares have been taken up out of a capital of £50,000, in £10 shares, and of these 650 have been issued as fully paid. The full amount has been called and paid on the remaining 1,350 shares. The principal shareholders are :—The Brush Electrical Engineering Company (Limited), with 699 shares, and Messrs. Otis Brothers and Co., of New York, with 420 shares.

PLANET ELECTRICAL ENGINEERING COMPANY (LIMITED).—The annual return of this Company, made up to August 18th, has been filed. The nominal capital is £30,000, divided into 4,000 Ordinary shares of £5 each, and 2,000 £6 per Cent. Preference shares of like value, of which 3,482 Ordinary and 160 Preference shares have been taken up. Of these 800 Ordinary shares were issued as fully paid, and the full amount has been called on the remainder. The sum received in respect thereof is £14,210.

SALISBURY ELECTRIC LIGHT AND POWER SUPPLY COMPANY (LIMITED).—The statutory return of this Company, made up to July 13th, has been filed. The capital is £20,000, in £1 shares, and 257 of these have been taken up. In response to a call of £1 per share, the full amount has been received. The principal shareholder is John M. Benett-Stamford, J.P., of Tisbury, Wilts, with 250 shares.

SINGLE WIRE MULTIPLE TELEPHONE SIGNAL COMPANY (LIMITED).—The annual return of this Company, made up to June 21, 1894, has been filed. Out of a nominal capital of £5,000 in £10 shares, 254 shares have been taken up, and the full amount called, resulting in the total payment of £2,540.

SPANISH NATIONAL SUBMARINE TELEGRAPH COMPANY (LIMITED).—The annual return of this Company, made up to August 24th, has been filed. Out of a nominal capital of £500,000, divided into 49,900 Ordinary shares of £10 each, and 1,000 Founders' shares of £1 each, 23,719 of the former class have been taken up and allotted. Of these 23,715 have been issued as fully paid, and the full amount has been called and paid on the remaining four shares.

ST. NICHOLAS CONSTRUCTION COMPANY (LIMITED).—The statutory return of this Company, made up to September 1, 1893, was not filed until June 29th last. Only the 7 signatories' shares out of a nominal capital of £40,0000, in £20 shares, have been taken up, and although the full amount has been called, nothing has as yet been paid.

CITY NOTES.

BOLCKOW, VAUGHAN AND CO.—The Directors of this Company announce that the results of the half-year's working to June 30th last are fairly satisfactory, but that it has been decided not to recommend an interim dividend, but to wait until the results of the full year's working are known. A similar course was adopted last year.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended September 9th were £840, as against £754 in the corresponding period of 1893, being an increase of £86. The total receipts for the half-year amount to £8,576, as against £8,148 for the corresponding period of 1893, an increase of £428.

CITY OF WESTMINSTER ELECTRICAL SYNDICATE (LIMITED).—A general meeting is to be held on the 17th prox., at 10 a.m., to receive the Liquidator's report and an account of the winding up of the Syndicate. The meeting will be held at 39, Eccleston-place, London, S.W.

COMPAGNIE FRANCAISE DU TELEGRAPHE DE PARIS A NEW YORK.—In reference to the proposed winding-up of this Company, a meeting is to be held on the 29th at the Paris offices. In order that the resolutions proposed at the meeting may be validly passed it is necessary that the total shares represented by voters be over £42,000.

DALZIEL'S CABLE NEWS AGENCY (LIMITED).—An extraordinary general meeting of the members of this Company was held on the 29th ult., at which a resolution was passed that the Company be wound up voluntarily, and that Mr. J. M. Henderson, of 2, Moorgate-street Buildings, London, E.C., be appointed liquidator.

LONDON, WALTHAMSTOW, AND EPPING FOREST RAILWAY.—Some details are given of the scheme of this railway, the construction of which was authorised during the last session of Parliament. The promoters have powers to use either steam or electricity. The railway commences at South-place, Finsbury, E.C., and proceeds underground through St. Luke's, Hoxton, Shoreditch, Kingsland, Hackney, and Upper Clapton, some of the most densely populated districts in London. From Upper Clapton the railway continues through Walthamstow, Chapel End, and Chingford, skirts Epping Forest, and terminates at High Beech. The railway will thus afford accommodation in a district now only partially catered for. Connections are to be effected with the Great Eastern, Midland, and London, Tilbury and Southend Railways, and to the Midland Railway in particular the new line should be of especial service, as it will enable a service of trains to be run from Moorgate-street viâ the Tottenham and Hampstead line to South-place, Finsbury, the terminus of the new railway. The capital of the Company is £2,100,000, and the total length of the line 14 miles. It is supported by the three companies with which it communicates, and has so far met with the approval of the County Council. The railway is to be constructed on the Greathead shield principle.

NORTH BORNEO TELEGRAPHS.—The British North Borneo Company has received a telegram in connection with the laying of the telegraph line across the country, to the effect that about 90 miles of the total track has been cut, and that gangs of men are now engaged in exploring the mountain route and cutting posts.

PORTRUSH ELECTRIC RAILWAY.—Viscount Templetown, M.I.E.E., has been elected a Director of this Railway in succession to Lord Kelvin.

SOCIETE FRANCAISE DES TELEGRAPHES SOUS-MARINS.—The report of the Directors of this Company states that the traffic receipts for 1893 amounted to £29,900, against a little over £30,000 for 1892. An increase of £630 over 1892 has been received in subventions and guarantees, due to an increased payment by Curaçao. A further sum of £2,000 will be received next year as a subvention from Guadaloupe. The Directors think that, considering the circumstances under which the business of the Company has been carried on during 1893, the receipts are satisfactory. Negotiations were some time ago entered into for a cable to connect the West Indies with New York direct, or viâ Bermuda, but these negotiations fell through, and the Société devoted its attention to the scheme for cable communication with the Azores, which, however, was not successful, the concession being granted to an English company. The Société are energetically working on their original scheme for a cable to New York, and the Directors look with hope to a satisfactory result being attained in the near future. A satisfactory increase is reported of work from the Company's station in Hayti. The general meeting of the shareholders will be held on the 27th inst.

STEEL COMPANY OF SCOTLAND.—The shareholders of this Company at their annual meeting in Glasgow on Tuesday agreed to raise £250,000 to meet debentures falling due. The new issue is to be £150,000 Five per Cent. first-charge stock and £100,000 Six per Cent. second-charge stock. The Chairman, in the course of his remarks, said that the present prices of steel were unremunerative.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended September 7th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £2,887.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 853.—Vol. XXXIII. FRIDAY, SEPTEMBER 21, 1894. PRICE FOURPENCE *Annual Subscription (U.K.), 19/—*

NOTES.

It will be news to electrical engineers to learn that they are working under better legislative conditions than those who are in charge of gas undertakings. It will also be news to those who have endeavoured to secure the ear of this or that provincial town council to learn that electrical engineers "have not been hampered with the cry of monopoly." The minimum charge clause, which figures in every Electric Lighting Order, but which for business reasons is never enforced, is, according to an article in the *Journal of Gas Lighting* by Mr. Norton H. Humphreys, another gas grievance, though one would think that the hardship of having always to be in readiness to supply was reduced to something approaching zero when cheap and efficient means of storage are available. Nevertheless, if gas engineers want similar powers, we feel sure electrical engineers will be pleased to assist them in this respect, and delighted to see them put their powers into operation. Nothing could be more calculated to hasten the advent of the electrical millenium than harrying gas consumers by charging for gas not actually used.

But, to quote Mr. Humphreys' own words, "we have, however, not yet exhausted the advantages afforded to electricity as compared with gas." Electric light companies, he points out, may test indoor wiring and refuse to supply current to customers who disturb their neighbours' light by the use of improper appliances. We were under the impression that users of gas engines were *obliged* to fit their supply pipes with "anti-fluctuators," and would point out that a leak in a house wire in Belgravia may very possibly give rise to complications in Westminster, a contingency for which there is no gas analogue.

Lastly, it would appear that "electricians have a unit of price that is really a unit," and Mr. Humphreys proposes that gas should in future be sold by "hundreds" as "it carries a better impression to have a low-priced unit than one that runs into shillings and pence." How short-sighted were those prospective suppliers of electric energy who some years ago urged the Board of Trade to enlarge the supply unit tenfold, so that they might be able to reduce their charges by something more appreciable than a halfpenny at a time, and yet by steps of something less than 6 per cent. But perhaps the gas people are contemplating a series of inappreciable jumps *upwards*. It only remains for gas engineers to complain that they started business without a rival, before the era of municipalisation had dawned, and without a municipal purchase clause. Truly, electrical engineers have not properly realised the advantages of their position.

The discussion on the Liverpool Overhead Railway, which is concluded in our columns this week, and which is followed by some Correspondence, would have been of even greater interest if a few more railway men had taken part in it. Mr. A. McDonnell drew attention to the ambiguous use of "train-mile" in attempting to base comparisons between different systems, and Mr. A. F. Aspinall in the Correspondence called attention to "engine-mileage." A unit of passenger-mileage is but little better, for differences of frequency of service and of speed cannot be neglected. The only possible mode of comparison is to estimate from general experience how much it would cost to run a given electric line by steam or otherwise. In a long discussion, such as that on the Liverpool Overhead Railway, the speakers are answered by each other rather than by the authors. The cost of carbon brushes, amounting to no less than £6 per week at first, and even £2. 10s. per week in March last, is rather remarkable; but equally satisfactory was Mr. Siemens's statement that one of his locomotives on the City and South London Railway had run 50,000 or 60,000 miles with the set of brushes delivered with it.

Our readers will remember that in *The Electrician*, Vol. XXXI., p. 311, we described a 30-ton gearless electric locomotive, which was manufactured by the General Electric Company, of America. In the same issue we commented on the performance of this engine. We now learn that the manufacturing company referred to has recently brought out a larger and modified form of this locomotive. The latest pattern weighs forty tons, and is stated to give a draw-bar pull of 14,000lb., or about one-sixth of the weight. This is a much more reasonable allowance than was made in the former case. Instead of one motor truck there are now two, each having the four wheels fully utilised for adhesion. We welcome the news that this 40-ton engine "is now standing in the factory yard," and hope that it will soon leave the yard for the rough-and-tumble duties of a permanent way. Electric traction in America possesses not a little interest for the British electrical engineer, and it is instructive to observe the pleasure with which the American electrical engineer hails the advent of a 30-ton locomotive in 1893 and a 40-ton locomotive in 1894. We have not many

Digitized by Google

electric locomotives in this country, perhaps; but, such as they are, they largely make up in efficiency, and in the amount of tractive force per ton of driving machinery, what they lose in numerical strength. On the Liverpool Overhead Railway a tractive force of 750lb. per ton is obtained, as against 373lb. per ton of the locomotive recently manufactured in America, and 234lb. per ton of the steam engines of the District Railway. The principal reason for the high figure attained by the Liverpool locomotive lies in the careful disposition of the load on the wheels, giving a tractive force which is simply impossible with separated locomotives and coaches.

The economy of connecting lamps in series may be studied by those who are interested in the question, with reference to the curves which we reproduce from Dr. Fleming's forthcoming book on "Electric Lamps and Electric Lighting." At the time when Dr. Fleming arrived at the results embodied in these curves, it is probable that modern lamps of 2½ to 3 watts per candle were not regularly on the market. In the first curve 16 c.p. appears to correspond to about 0·625 ampere, or, at 100 volts, 3·9 watts per candle, and 22·5 c.p. to 0·67 ampere, or 3 watts per candle. The former condition corresponds to the old lamps, and the latter to modern ones. In problems of this kind the absolute candle-power does not matter at all. Mr. T. B. Sharp informs us that he reduces his current from 3½ amperes to 1½ ampere, and gets "a pleasant mellow light." There is a great difficulty in making photometric measurements of "pleasant mellow light" from a red hot poker or any such subdued source of light. Unfortunately, neither Dr. Fleming's curves, nor those supplied by Prof. Ayrton, and published in *The Electrician*, Vol. XXIX., p. 281, nor anything in Mr. Ram's book, give a clue to what Mr. Sharp really gets, for it is beyond the limits of their experiments, and seems to correspond to less than half a candle-power. Whatever it is, it seems to be very agreeable to Mr. Sharp, and, according to his ammeter, saves four-sevenths of his current.

It appears, from a letter which we print this week, that in some cases the use of a solid carbon for the top, and a cored carbon for the bottom in an alternate-current arc, will get rid of the band of violet light to which we alluded a fortnight ago; but we believe that this is not complete cure. The vagaries of the alternate-current arc, especially when small—say, less than 11 amperes—are at present inexplicable, or, at all events, unexplained.

The alternate-current meter invented by Mr. Thomas Duncan, of the Fort Wayne Electric Company, while it appears from the maker's tests to be an accurate instrument, marks no great advance. The principle of the instrument, which is briefly described in another column, may be said to combine those of the Shallenberger and Ferranti-Wright meters. It is an ampere-hour instrument, and, if we may be allowed the expression, it measures all the amperes that pass through, whether wattless or business amperes. For lighting purposes, even with arc lamps, such a meter may suffice; but with motors on the circuit it must register in favour of the supply company. We are still waiting for an alternate-current meter that can be made in quantities and stocked by manufacturers or agents like continuous-current meters, ready to be put into circuit on any alternate-current service, whether supplying glow lamps or motors, whether with flat-topped magnetism waves for increased transformer efficiency, or flat-topped current waves for arc lamps, or sine waves for American use.

Some radical improvement of alternate-current motors, whereby they may be run on a circuit with 100 periods per second as well as at a lower frequency, seems to be the only hope for uniformity. At present neither voltmeters, ammeters, house-meters, arc lamps nor motors for alternate currents can be safely stocked and catalogued by dealers. Motors, it is true, can be bought at the purchaser's discretion; but the speed and output are not under his control as with a continuous current motor. Measuring instruments in nearly all cases have to be adjusted, if not specially calibrated, for the particular frequency. If a standard of 100 could be kept, the difficulty would disappear; but low frequencies are sometimes used, as a concession to motor makers. Is it worth while for makers of arc-lamps to carry out elaborate experiments with the view of designing a mechanism which is suited for a current of any frequency between 40 and 100, and for flat-topped or for sine waves? Probably not.

A correspondent informs us that we will possibly confer a boon to mankind by kindly informing him if there is any substance in nature that will (though it may be colourless) turn black or other colour when in contact with electricity. We should be glad to send him a bit of pole-finding paper if we knew his address, but we do not know how he is going to bring it "in contact with electricity." We know nothing about "electricity"; the word is very rarely used except by accident in the editorial columns of *The Electrician.*

Cable Interruption:	Date of Interruption.
Zanzibar-Mombasa	September 4th.
Benguela-Mossamedes	September 16th.

International Telephony.—Madrid and Paris will be shortly telephonically united. On the Spanish side, the wires have been stretched as far as Saragossa; in France, the line has already been carried from Paris to Tarbes.

Edison Feeder and Thomson-Houston Dynamo Patents.—The Edison "feeder," patent No. 3,880, of 1880, expires by due process of law on Monday next, and the Thomson-Houston arc light dynamo, patent No. 3,928, comes to a similar end to-day week.

Budapest.—A proposal to construct an electric tramway between Budapest and Budafok is under consideration. The contract for the ironwork required for the Budapest underground electric railway—about 2,000 tons—has been given to the Rima Murany Salgo Tarjan Ironworks Company.

Manchester Municipal Technical School.—The syllabus for the session 1894-95, issued by the Manchester City Council, contains a full description of the classes to be held. A large amount of useful information is given, and the book is made additionally interesting by a number of illustrations showing the interior views of the laboratories.

Digitized by Google

Popular Lectures.—The programme of popular evening lectures, at the Merchant Venturers' Technical College, Bristol, includes a lecture by Prof. H. S. Hele Shaw, on "Graphic Methods in Science," and another, by Prof. Wertheimer, on "Electricity *versus* Gas." These lectures will be delivered on Wednesday evenings during the winter session.

"L'Eclairage Electrique."—Within a month of the disappearance of *La Lumière Electrique*, M. P. H. Ledeboer, a well-known contributor to the French technical press, has stepped into the breach with a similar publication called *L'Eclairage Electrique*. We hope M. Ledeboer's plucky venture will meet with the success it deserves. The offices of our new contemporary are at 24, Rue Chauchat, Paris.

Heriot-Watt College.—We have received the calendar of the Heriot-Watt College, Edinburgh, for the forthcoming session. The courses of lectures and practical instruction in electrical engineering and electro-technical subjects, which are under the direction of Dr. R. M. Walmsley, are well arranged, and they have been designed to meet the needs of day and evening students. The new session commences on October 1st for the evening work, and on October 9th for the day work.

Destruction of Lighting Plant at Little Rock, Arkansas.—The city electric lighting plant at Little Rock, Ark., was recently disabled by some unknown miscreant putting sulphuric acid on the commutator and armature coils of the dynamos. The plant had been in operation since May 7th, and was furnishing current to lamps for street lighting. A former employé of the city was suspected of the crime and was arrested. Superintendent Fish, the electrician in charge of the station, was suspended by the mayor when the matter was brought to his attention.

Telegraphs and Telephones in Western Australia.—There has been a considerable increase in the receipts from the telegraphic and telephonic systems in Western Australia during the past financial year, no doubt due to the great development in mining operations which is taking place in that colony. The following table shows the receipts from the two sources during the past two years:—

	1893-94.	1892-93.
Telegraphs	£19,204	£15,509
Telephones	2,004	1,602

The World's Telegraph Offices.—The International Telegraph Bureau, at Berne, has just issued the official list of telegraph offices throughout the world. This work has now reached its ninth edition, the object of its publication being to assist in calculating the charges to be collected on international telegrams. The list contains the names of all offices notified to the Berne Bureau as open for international telegraph correspondence. Accompanying the list is some useful information concerning the collection of telegraphic charges in various parts of the world.

Fatality at Leicester.—A youth named Hugh Smith met with an extraordinary death early on Monday morning at the Midland Station, Leicester. He was, in company with Joseph Attfield, in charge of the dynamo connected with the electric light. Attfield suddenly heard a cry, and found Smith on the floor with blood flowing from his mouth, ears, and nose. The railing round the engines was bent, but there was no appearance of the youth having come in contact with the live conductors. He died in a few minutes from loss of blood. Under these circumstances, the officials, who subsequently inspected the place, are unable to account for death. The most favoured hypothesis is that the deceased was examining the bearings of the engine, when his sleeve became entangled in the shafting, and that after being hurled on to the brass guard he was thrown to the ground.

Remarkable Views on Electric Currents.—A German electrical contemporary publishes a communication from Dr. Stricker and Herr Deutike, in which it is announced that the authors have discovered some very remarkable properties of the electric current. According to these investigators, in every closed circuit there exist two currents flowing in opposite directions, one a current of positive and the other a current of negative electricity. Among other things they state that Volta's fundamental experiments depend not on the contact, but on the approaching or receding of the heterogeneous metals, the source of the current being the mechanical work exerted by the experimenter; and they claim that the ions do not migrate through the whole electrolyte. Their deductions appear to be based on experiments, but it remains to be shown that the experimental evidence warrants such departures from recognised views on the subject.

Obituary.—We regret to record the death of Mr. Ernest Cunard Cummins, electrician of the Western and Brazilian Telegraph Company's repairing steamer "Norseman." Mr. Cummins was out shooting at Santa Catharina, Brazil, when the gun of a companion accidentally went off, wounding him seriously in the leg, and he died within a few hours from his injuries. He had been in the Western and Brazilian Company's service for many years, and was considered an able electrician. A general favourite, his death will be mourned by many friends, both at home and in Brazil.—The death is also announced of Mr. R. E. Maunsell, clerk-in-charge, the Eastern Telegraph Company's Station at Porthcurnow, Penzance. On Saturday last Mr. Maunsell was mounting a horse outside his house, preparing to go for a ride, when the animal reared and threw him off, and then kicked him heavily in the face. Mr. Maunsell sustained a severe concussion of the brain, and died after only a brief interval of consciousness.

Electric Heating of Cars.—In winter time the heating of the cars running on the Salève Electric Rack Railway (see *The Electrician*, Vol. XXXI., p. 494, September 8, 1893) is effected by current taken from the main circuit. The heaters consist of two resistance frames, placed under the seats at either end of the car. Each seat is 0·82m. long, 0·3m. high, and 0·18m. deep, and contains 42 spirals of 1·5mm. galvanised iron wire, each spiral containing 5·92m. of wire, and being 24mm. in diameter, so that the total length of wire in the two heaters amounts to no less than 500 metres. All the spirals of each heater, and the two heaters themselves, are connected in series. The current absorbed is 15 amperes, which, at a pressure of 500 volts, represents 10 H P. The temperature of the iron wire rapidly reaches 100°C., and even during the severest weather the car is warmed to 15° or 20°C. in 10 minutes or a quarter of an hour.

Science Sifted Out.—A contemporary of the name of *Science Siftings* presents its readers with the following startling piece of information:—"Sir William Preece (*sic*) has told us of the possibility of telegraphing without wires by means of the magnetic currents in earth and water. Is it not conceivable that the Arabs of Africa may be acquainted with these possibilities and have been applying their knowledge of them to the transmission of news? This is one of the most plausible explanations. There is nothing new under the sun, not even concerning electricity; and a theory has even now been put forward that the peculiar cylinders discovered among the ruins of Nineveh, bearing, not characters, but faintly marked lines, may be nothing more nor less than the cylinders of some ancient Assyrian phonograph. Should this supposition prove correct we may yet hope not only to read the writings, but even to hear the voices of those Wise Men of the East whose civilisation antedates ours by many thousand years."

Telegraphy and the Bursting of the Gohna Dam.—Details of the bursting of the Gohna dam on the 26th ult. have been received at Brindisi by mail, and wired thence by Reuter. On August 24th, at 8 o'clock in the morning, an automatic bell placed within a foot of the top of the dam sounded the first note of alarm. The warning was communicated throughout the whole of the threatened territory almost instantaneously by means of telegraphic messages, bonfires, rockets, the beating of drums, and other signals, and the people immediately fled with all their cattle and personal belongings into the hills. In this way ample warning was given and the apprehended loss of life averted. At Hardwar all Government buildings, with the exception of the telegraphic office, were destroyed. Here an incident occurred which exemplifies the excellent behaviour of the telegraph staff throughout the entire district affected. The commissioner of Hardwar ordered the chief of the telegraph office to leave his post when the flood was advancing, but the man wired back to headquarters that he would stop till the last moment and save himself if necessary by running

Digitized by Google

up the hill. The whole overflow was discharged in about two hours.

The "Manhattan" Incandescent Arc Lamp.—Our American friends seem never likely to tire of devising novel methods for prolonging the life of the arc lamp. Last year (Vol. XXXI., p. 502) we described the "Marks" lamp, shown before the Chicago Electrical Congress; to-day the American journals contain descriptions of a variant on the "Marks" lamp, called the "Manhattan" lamp. Its most important feature is an outer globe, air tight at all points except at the bottom, where there is a hand-hole, and an inside globe which acts as a rarefied chamber. On the formation of an arc the enclosed air is heated and rarefied, the surplus air escaping through the lower vent. The contained oxygen is soon reduced by combustion with the carbon points to carbon monoxide, and this, with the remaining nitrogen, surrounds the arc, and protects the points from further combustion. By this system the burning of carbons in these enclosed chambers half-inch carbons will, it is said, burn 80 hours without retrimming, and without any blackening or discolouration of the globe. Owing to the high potential at which it is possible to burn the arc in this enclosing chamber, the efficiency of the lamp is greatly increased.

Electric Communication with Rock Lighthouses.—At the conclusion of the inquiry into the recent stranding of the Cape liner "Dunottar Castle," on the Eddystone rock, Mr. Garrett, on behalf of the owners, said they courted the inquiry because it seemed to them to attract attention to the absolute necessity for having telegraphic communication between such places as the Eddystone Lighthouse and the shore. In this case the value of the ship and cargo was over £300,000, and there were 400 lives on board, and the ship was within measurable distance of being totally lost for the want of assistance, which might readily have been obtained from Plymouth if there had been the means of communication. Mr. Baden-Powell, who appeared for the Board of Trade, said that as to the propriety of communication between lighthouses and the shore, the subject had been under consideration for some time, and the idea was much applauded by those who owned ships and knew the dangers of the coast; and it was a question upon which he thought an expression of opinion might be given by the Court. After giving judgment the Court added, with reference to the suggested electric cable between the Eddystone Lighthouse and the shore, that the Court would consider the subject and make some remarks upon it in their report.

The Telephone in the German Army.—An interesting military experiment took place last month between Berlin and Potsdam. A telephone line was laid on the march by two cavalry patrols, each consisting of an Uhlan officer and two Uhlan under officers; one starting from Berlin, the other from Potsdam, very early in the morning. Each patrol was furnished with a complete telephonic apparatus carried by one of the under officers, and a supply of steel wire wound on reels, each containing 1 kilometre of wire. The laying of the line began in Berlin in the following manner: The end of the wire was connected to the town circuits in Berlin, and the spool fixed on a carrier in such a way that the wire could unroll as the man rode along. A second man rode behind, furnished with a sort of fork on the end of his lance, making it about half as long again; in this he caught the wire, and as they went along threw it into the upper branches of the trees lining the chaussée. Choosing roads furnished with trees, they rode along; the officer first, and behind the two men running the wire, about 30 paces apart. When the first bobbin was finished, they halted. The telephone was connected, and a horn blown to signal to the starting point, a similar signal being the reply. Conversation having been held, the new bobbin was joined up and the process continued. At Teltow the two patrols met; the two ends were signalled, and then the wires joined together, and speech was excellent from Berlin to Potsdam. The order was then given to take up the circuit, which was done. The laying of the circuit of 30 kilometres took not more than four hours.

Gas and Electricity in Berlin.—A report on commerce and industry in Berlin during 1893 gives interesting figures relating to gas and electric light, which show that the competition of the latter is beginning to tell. For many years back the yearly increase in gas consumption ranged from 4 to 6 per cent.; in 1892 it fell to about 3¼ per cent., while in 1893 the production actually fell nearly 1 per cent. The fall is exclusively due to private lighting, which took 1¾ million cubic metres less than in 1892, while the public lighting took 600,000 cubic metres more, and the supply for heating, &c., to private consumers also rose about 800,000; the total consumption falling by 300,000 cubic metres. The fall in production to a very great extent is due to better results as to losses in mains, &c. This fall is ascribed to four causes: bad trade, competition of the electric light, the increased use of the Auer incandescent burner, which is much more economical than the old types; and, finally, the Sunday rest, legally enforced since July 1, 1892. The population has risen in the year by 33,500 persons, about 2 per cent., and the consumption per head has fallen from 81·0 to 78 9 cubic metres. The output of gas motors connected has risen from 4,340 to 4,758 H.P., the output of the engines varying from 60 H.P. downwards. On the other hand, these somewhat disappointing results are far surpassed by the electric power stations. The production of energy from private plants is enough to supply 3,870 arcs, and 69,360 16-c.p. glow lamps, being an increase of six arcs and 14,400 glow lamps. The Berliner Elektricitätswerke, on the other hand, feeds 4,931 arcs, 102,705 glow lamps, and 322 motors. The total increase is 780 arcs, 31,790 glow lamps of 16 c.p. and 130 motors. This increase corresponds to an increase of 19·96 per cent. in the total consumption. The consumption of electricity for private lighting is about 25 per cent. of the energy used for this purpose as gas, against 21·62 per cent. last year (1892).

Gas and Electric Light Conduits.—At the recent Congress of the Société Technique du Gaz en France, at Nimes, an account of an explosion of gas which occurred in the vicinity of some electric light cables was given by M. Gaston Gautier. The explosion took place in Nantes. The three-wire system is in use; the wires being naked, and resting on porcelain supports. The branch wires are insulated. The contract under which the Electric Light Company work compels them to put a cable under each footpath, except in narrow streets. The street in question had but one footpath, and only one main had been laid; and the branch which crossed the street was formed of two insulated wires, separated, and placed in a cast-iron conduit having lead joints. At the spot where the explosion seems to have originated, a branch electrical service crossed the street in a cast-iron pipe about 3½ inches in diameter. The principal conduit having been uncovered at this point, it was found that the negative wire of the branch was broken at the entrance to the pipe. A trench opened in the direction of the pipe revealed right and left—about 16in. on one side and 5ft. on the other—two lead pipes conveying gas into the neighbouring houses. Each of these pipes was enclosed in a box made of deal, which had been steeped in sulphate of copper. But the vertical sides of one of these boxes had been sawn at a certain spot, doubtless to allow for deflection; and there was a rupture at the junction of the two parts of the other box, which made connection. It was precisely at these two places that large holes were found extending lengthwise along the pipe. Undoubtedly, a very considerable escape of gas took place through the perforations, and, following the line of wooden troughs, reached the electric light mains, and formed with the air contained therein an explosive mixture. The perforations must have been formed very quickly, and have preceded the explosion by only a short interval, as the openings were too large to have existed any length of time without giving indications of their presence by allowing a large escape of gas through the soil or in the consumer's house. It therefore appears reasonable to admit that the perforations were produced under the action of an electric short-circuit. As a result of this explosion the following regulations were agreed to by the parties:—No work to be done by either of the companies in the vicinity of the mains of the other without due notice being given; the Electric Light Company to substitute earthenware casings for those of cast iron for their branch services; and branch gas service-pipes in the neighbourhood of electric light mains to be laid in wooden boxes into which there will be run natural bitumen.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(Continued from page 511.)

Theory and Action of the Steam Engine.

Engine Horse-Power.—Every engine is required to be able to develop a certain amount of power for the performance of useful work, and to be capable of running at any value below and up to a certain value above a standard or normal power. As a rule, an engine is also required to be able to develop power at a certain normal speed, and to be capable of working above or below this speed, within certain limits which are fixed by the class of work for which the engine is designed. In maintaining itself in motion, the engine will expend some power against the frictional resistances of its moving parts; so that the total power whi h it must develop will always be greater than the useful power which it is required to give off. In a steam-engine or other heat engine the total power developed by the working substance within the engine is called the indicated horse-power (I.H.P.), and the power given off is called the actual or brake horse-power (B.H.P.). The difference represents the internally wasted power, due to engine friction. The normal power which the engine is designed to develop or give off is called the rated horse-power, and in many cases this is of much lower value than the maximum power which may be obtained from the engine.

In all steam engines except the rotary type, which will be considered separately, the energy of the steam is exerted on a reciprocating piston, usually so connected to the crank shaft that the piston makes two *strokes* during each revolution of the shaft. We may, therefore, consider the I.H.P. as being the product of the number of revolutions or strokes per minute into the average work done during each revolution or stroke. If the engine is working on a steady load, and at a steady speed, the work done during every revolution will be constant. In double-acting engines the steam is exerted alternately and similarly on both sides of the piston, so that the work done during each revolution is just twice the work done in one stroke. In single-acting engines the steam is idle during each alternate stroke, and the indicated work done in each revolution is the same as during one working stroke. Calling w the work done by the steam in each working stroke, N the number of revolutions per minute, p_e the mean effective pressure of the steam in pounds per square inch, A the area of piston acted on by the steam in square inches, and L the length of stroke in feet, we therefore obtain the following expression for the I.H.P. of any single cylinder:—

$$\text{I.H.P.} = \frac{k\,w\,\text{N}}{33{,}000} = \frac{k\,p_e\,\text{A}\,\text{L}\,\text{N}}{33{,}000}. \quad . \quad . \quad (84).$$

In single-acting engines the constant k is equal to 1; in double-acting engines it is equal to 2. In engines having more than one cylinder the total I.H.P. of the engine is equal to the sum of the I.H.P.'s of the separate cylinders, as determined by the above equation.

In order to determine the mean effective pressure of the steam throughout the working stroke, it will be necessary to ascertain the variations of steam pressure and of back pressure on the piston during this period. Since the variation of back pressure on the opposite side of the piston is the same as the variation on the side under consideration will be during the return stroke, the mean effective pressure is usually determined by taking the algebraic mean of the absolute steam pressures on only one side of the piston during an entire to-and-fro motion of the piston, the pressure being considered positive when it is an effort, and negative when it is a resistance. The diagram representing this complete variation of steam pressure on only one side of the piston is called an *indicator diagram*. It is usually drawn on rectangular axes, with ordinates of pressure, and abscissæ representing the positions of the piston. The value of p_e is found by taking the intercepts of the ordinates between the upper and lower portions of the diagram, the mean being found by any convenient process. If the tracer of an integrating planimeter is passed round the diagram, the reading on the instrument will represent the value of w.

Steam Economy.—Having now fixed the quantities upon which the power of a steam engine depends, it will next be necessary to consider their influence upon the all-important question of steam economy. Not only is it requisite that the engine shall be able to give off a certain B.H.P., and to work as occasion requires at full load, half load, and so on, but it is essential to commercial success that the steam consumption under these conditions shall be low. The actual B.H.P. having been fixed upon, it is possible to obtain it by an immense number of combinations of the quantities in equation (84), as well as to subdivide the power among two or more cylinders on the same engine. These variations of the several quantities lead to the creation of the diverse types of steam engines. With respect to N, the engines may be classified under *high speed* or *low speed*; with respect to N and L combined, they are classified as *high piston speed* or *low piston speed* engines; with respect to p_e, the distinction between *high pressure* and *low pressure*, between *simple*, *compound*, and *triple* expansion, and between *condensing* and *non-condensing* engines arise. Besides these types, we may mention the classification under *horizontal* and *vertical* engines, and the distinction arising from the type of valve in use in the engine.

The sources of ineconomy in steam engines may broadly be classed under the two heads: failure to obtain indicated work from the energy of the steam, and dissipation of the indicated work in overcoming engine friction. We will now proceed to make a detailed examination of these two sources of ineconomy, considering them in relation to the various types of engines and the quantities upon which those types have been stated to depend. We will commence with a study of ineconomy arising from failure of the engine to obtain indicated work from the steam supplied to it.

Distribution of Steam in the Cylinder.—The first requisite is an exact knowledge of the distribution of steam in a single cylinder during one complete revolution of the engine shaft. In Fig. 25 let O A represent the clearance space behind the

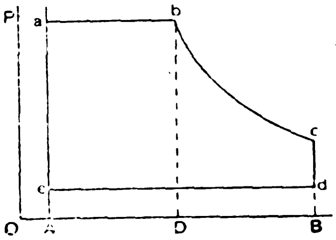

FIG. 25.

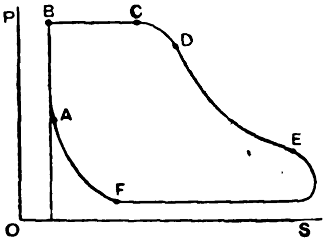

FIG. 26.

piston at the beginning of the stroke (assuming the steam port to be closed), and let A B represent the length of the stroke on the same scale. The clearance is expressed as a length by dividing its volume by the area of the piston. Let ordinates drawn above O B represent the absolute steam pressures in the cylinder. In order to obtain work from the intrinsic energy of steam, a portion of steam is admitted into the cylinder during the early part of the stroke, is then isolated or "cut off," and is expanded during the rest of the stroke. This may be represented by the line $a\,b\,c$, the piston commencing to move at A under full steam pressure, moving to D under full pressure, cutting off steam at D, and expanding the steam from D to B. At c the steam is released by the opening of the exhaust valve, and the pressure may be supposed to fall to d, the ordinate of which represents the pressure of the exhaust. The return stroke may be assumed to take place against this back pressure; and on reaching e the piston is once more subjected to full steam pressure by the opening of the steam valve. The volume of steam in the cylinder at the point of cut-off is represented by the distance, O D, and is equal to the clearance volume plus the volume swept through by the piston. The ratio of expansion is therefore

$$\text{R} = \frac{\text{L} + c}{l + c}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (85)$$

where c is the length of the clearance space.

*** From a forthcoming work to be published by *The Electrician* Printing and Publishing Company.** **All rights are reserved.**

Digitized by Google

The steam admitted to fill the clearance space does work on the piston only during the expansion period, and is therefore to a certain extent idle. During admission, however, it does internal work on itself, superheating or drying itself, and this work may be partially utilised in the subsequent expansion.

In practice it is impossible, as well as undesirable, to get such a distribution of steam as that shown in Fig. 25. It is impossible, because the sudden opening and closing of the valves which give the sharp angles at *a*, *b*, *c* and *e* cannot be obtained in practice, and because a perfectly uniform back pressure during the entire back stroke is inconsistent with the conditions of working. It is undesirable, because of the shocks to the working parts which would result from the sudden changes in pressure and from the reversals of motion, and because it is not economical to allow the whole of the clearance space to be filled with live steam at each stroke. Fig. 26 may be taken as typical of what usually takes place, to a greater or lesser extent, in the distribution of steam during one revolution. The point of steam admission is shown in this diagram at A, and the line A B is usually called the admission line. In many engines, admission takes place before the end of the return stroke, in order that there may be a considerable opening of the steam port by the time the stroke commences. Late admission is shown by a rounding of the diagram at B. From B to C, where the steam is on the point of being cut off, is called the steam line. If the ports are well designed and the valves are properly set, the line B C will be practically horizontal; but where the steam is wiredrawn by constricting passages, there will be a gentle slope from B towards the cut-off. From C to D the valves are closing and cutting-off the steam, the rounding of the curve being due to increasing wiredrawing at the valves. E is the point of release, and from D to E the steam undergoes expansion. Pre-release of steam is very common practice, in order that the exhaust valves may be well opened by the time the back stroke commences. Late release of steam causes excessive back pressure during the early part of the return stroke. The exhaust continues until the point F is reached, and there may be either a steady or a variable back pressure during this period, according to the quality of the steam and the amount of opening of the valves. If there is water in the cylinder, re-evaporation of some of it during the return stroke may occur, causing a rise in back pressure. The point at which the exhaust port commences to close is always earlier than the end of the stroke, in order to enclose a small amount of exhaust steam and compress it into the clearance space. This compression is shown on the diagram between F and A. It is capable of easy proof, besides being in accordance with experience, that it is neither economical to allow the clearance space to be filled with fresh boiler steam at every stroke nor to completely fill it, up to boiler pressure, with compressed exhaust steam. The amount of compression which it is best to allow depends on the type of engine and on the ratio of expansion in the cylinder. With a cut-off at a quarter stroke, and a back pressure of 5 per cent. of the initial steam pressure, the best period of compression may be as much as 42 per cent. of the back stroke, while where the back pressure is 15 per cent. of the initial pressure, the best period will not exceed 26 per cent. of the stroke. Compression has another value beside in the economy of steam, for the rapidly increasing back pressure which it exerts on the reciprocating parts of the engine serves to arrest their momentum and to prevent an injurious knock on the bearing brasses.

Failure to Perform Indicated Work.—The passage of steam through the engine, including the jacket, &c., without the production of the full amount of indicated work represented by the range of temperature between admission and exhaust, arises from numerous causes, among which we shall particularly notice the following:—

1. Initial condensation of steam in the cylinder.
2. Insufficient expansion of steam during the working stroke.
3. Radiation and conduction of heat from the acket and cylinder steam.
4. Leakage of steam across the valves and piston.
5. Uneconomical distribution on account of badly designed or carelessly set valves.

Besides the foregoing avoidable sources of loss, it will be necessary to notice the reduction of available indicated work on account of

1. Avoidable lowering of the initial temperature of the steam; and
2. Avoidable raising of the exhaust temperature of the steam.

Initial Condensation.—One of the consequences of a distribution of steam such as that represented by Fig. 26 is a periodic fluctuation in temperature of the steam in the cylinder. Assuming the steam to be supplied in a saturated condition, the temperature at any point in the stroke may be determined from the absolute pressure at the point; from which it will be seen that, where any considerable amount of expansion takes place, there must be a considerable fall in temperature during the working stroke. Besides this, on release there is a further fall in pressure to that of the exhaust, and therefore a further fall in temperature. It is evident that the steam will always tend to equalise its temperature with that of the metal of the cylinder walls. An interchange of heat consequently goes on between the steam and the walls which, if permitted to take place on a large scale, will cause great waste of steam. Just before the closing of the exhaust port the cylinder is at its lowest temperature, as a rule, because it has had all the time from the point of cut-off up to the commencement of compression to give up its heat to the cooling steam. During the brief compression there is little time for any very great rise of temperature of the walls to occur, so that on the opening of the steam valve live steam rushes into a metal cylinder very much cooler than itself. Condensation of the saturated steam, in order to heat up the walls, is the inevitable consequence; and a greater volume of steam than is represented by the available space passes through the steam port. During the working expansion, a certain amount of re-evaporation may occur, thus partially recovering the useful effect of the steam; or, what amounts to the same thing, an equivalent weight of steam may fail to be liquefied isentropically. The re-evaporation is due to the lowering of pressure on expansion, when the hot water will have enough heat to enable part of it to attain the state of vapour. In the majority of engines, the condensed water has by no means completely evaporated at the point of release, the result being that a wasteful back pressure is set up during the exhaust stroke on account of the plentiful re-evaporation which goes on during that period. Various practices have been introduced in order to diminish the ineconomy of steam due to initial condensation, but there is probably no type of reciprocating steam engine in which this effect does not to some extent occur.

Prevention of Condensation.—Reference has already been made to the action of a hot jacket upon the working substance in a cylinder, and to the influence of a steam jacket upon the working liquefaction of steam. As a method of preventing initial condensation of steam, the use of a steam jacket has been found very beneficial. As far as the author has been able to ascertain, no instance of the economy of steam being injured by the use of such a jacket is to be found; while, in some types of engines, the improvement in economy is very marked. The effect of a live steam jacket is to tend to maintain the cylinder walls constantly at the temperature of the initial steam; but, owing to the movement of the piston, a heat gradient is set up in the cylinder walls, the inner strata of the walls being caused to fluctuate in temperature. Some condensation therefore takes place, even in the best jacketed engines; and the amount of this condensation is, other things being equal, proportional to the depth of cylinder wall which is affected by these fluctuations of temperature. It has already been shown that this depth is a function of the periodic time of the steam cycle. With rapid cycles the cooling steam has little time to abstract heat from the inner portion of the walls; with slow cycles the penetration of the cooling influence is very deep. In the former case the jacket is of little use; in the latter case the reduction of loss from condensation by its use is considerable. These considerations are completely borne out by actual trials

Digitized by Google

of high and low speed engines, in which it has been found that the value of the steam jacket is well marked in the latter type of engine, but scarcely appreciable in the former type. Some experiments mentioned by Prof. Cotterill* indicate that in the case of iron cylinders the depth to which the fluctuation of temperature penetrates, sufficiently to produce more than 0·2 per cent. of the fluctuation at the innermost surface, is given by the following table :—

Revolutions per minute	25	50	100	200	300	400	600
Penetration in inches..	0·894	0·632	0·447	0·316	0·258	0·224	0·182

(To be continued.)

ALTERNATING CURRENTS IN A DIVIDED CIRCUIT.

BY ALEXANDER RUSSELL, M.A.

The problem of finding the alternating currents in a divided circuit, when mutual induction is appreciable, is best solved by a geometrical diagram. The algebraical expressions for the impedance, &c., which have been appended in order to make the solution mathematically complete, can all be deduced from the diagram by elementary trigonometry. We can generally see much more easily from the figure what will happen on varying the frequency, resistance or inductance, than from the algebraical expressions.

Let (R, L), (S, N) be the resistances and self-inductances of the two branches, and M the mutual inductance. As usual, let $p = 2\pi\, n$, where n is the frequency. Let A_1, A_2 be the effective values of the currents, *i.e.*, the readings on an ammeter when placed in the two branches respectively. Also let V be the effective voltage across the two branches.

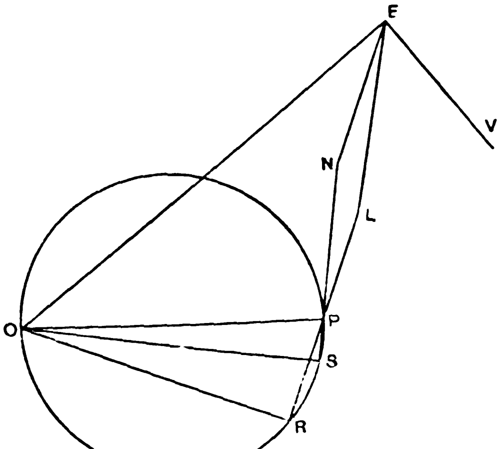

Fig. 1.

Then in the (R, L) branch the effective voltage V may be resolved into three components—$R\,A_1$, $p\,L\,A_1$, and $p\,M\,A_2$. The first component $R\,A_1$ drives the current A_1 through the resistance R, $p\,L\,A_1$ balances the back E.M.F. of self-induction, and $p\,M\,A_2$ balances the E.M.F. of mutual induction. It must be carefully remembered that M may be either + or −, depending on how the two coils are connected together. Similarly, in the (S, N) branch, the component E.M.F.'s are $S\,A_2$, $p\,N\,A_2$, and $p\,M\,A_1$. Also $p\,L\,A_1$ is perpendicular to $R\,A_1$, and $p\,M\,A_2$ is perpendicular to $S\,A_2$.

By the polygon of E.M.F.'s, V, $R\,A_1$, $p\,L\,A_1$, and $p\,M\,A_2$ form a closed figure. Similarly, V, $S\,A_2$, $p\,N\,A_2$, and $p\,M\,A_1$ form a closed figure.

Hence the general figure, showing how these quantities are related, is shown in Fig. 1, where $O\,R = R\,A_1$, $R\,L = p\,L\,A_1$, $L\,E = p\,M\,A_2$, $O\,S = S\,A_2$, $S\,N = p\,N\,A_2$, $N\,E = p\,M\,A_1$, $O\,E = V$.

* *See* Cotterill, "The Steam Engine," Chap. X.

Let N S meet R L in P. Then a circle goes round O R S P. Since S N and L E are both perpendicular to O S they are parallel, and also L R and E N are parallel. Hence P L E N is a parallelogram. We have now to show how to construct this diagram in any given case. A straightforward way of doing this is as follows :—

Draw (Fig. 2) two lines, $O\,S = S$ and $S\,P = p\,(N - M)$ at right angles to one another, and join O P.

Then (Fig. 1) draw $O\,R = R$, $R\,P = p\,(L - M)$, and join O P. Describe a circle on O P as diameter. Make the angle P O S (Fig. 1) equal the angle P O S (Fig. 2). Join S P. Make $R\,L = p\,L$, and $S\,N = \frac{N}{N - M}\,S\,P$. Draw N E and L E parallel to P L and P N respectively, and join O E. Then a little con-

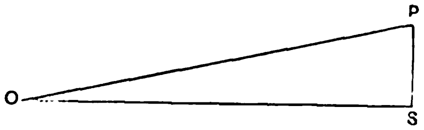

Fig. 2.

sideration will show that this is the diagram drawn to scale for the case of $A_1 = 1$ ampere. If we wish to find the currents, &c., for the case of $O\,E = V$ volts, we merely alter our scale so that O E equals V units. Then the lengths of the lines E L, E N, and E P, divided by $p\,M$, give the currents A_2, A_1, and A, where A is the current in the main circuit. The angles these lines make with E V, where E V is perpendicular to O E, give the respective phase differences between the currents and the E.M.F.

The joint impedance of the two branches is equal to $\frac{V}{A}$, which equals $p\,M\,\frac{O\,E}{E\,P}$. Measure a length, E D, equal to this along E P, and draw D F and D G perpendicular to E V and

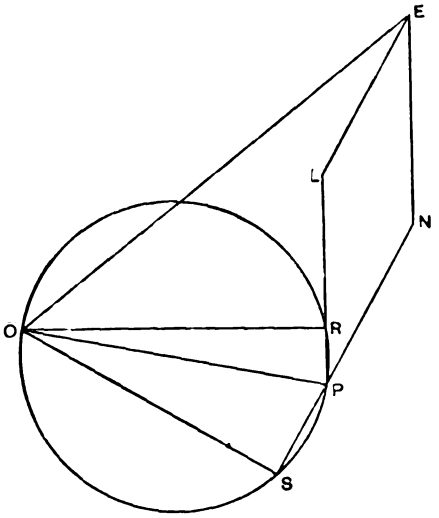

Fig. 3.

E O respectively (not shown in the figure). Then E F is equal to the effective resistance, and E G equals the effective reactance.

Three cases arise in practice, and we shall consider them separately :—

1. M less than either L or N.—This is the case shown in Fig. 1. We can see from the figure that when the frequency is very small, the phase difference θ between A_1 and A_2 is very small. When the frequency is very great, this phase difference is again very small. Hence, for some intermediate value of n, θ is a maximum.

2. M between L and N in value.—Suppose that M is greater than L. In this case $p\,(L - M)$ is negative, and P is below R. The general diagram is shown in Fig. 3. The phase difference θ increases as the frequency increases, and approaches 180deg. when n is large. In this case the currents are almost opposite in phase. Hence the current in the main

Digitized by Google

circuit is very little greater than their difference. It follows that if the currents in the two arms are nearly equal they will be very much greater than the current in the main circuit. This will be the case when L is nearly equal to N; the current in the (R, L) branch being nearly in the same phase as the main current, L being less than N. Just as when a condenser shunts a choking coil, we get a so-called "circulating current," so also in a branched circuit when the self-inductances are nearly equal and the mutual inductance lies in value between them we get a circulating current. These circulating currents are often very useful in alternating-current work.

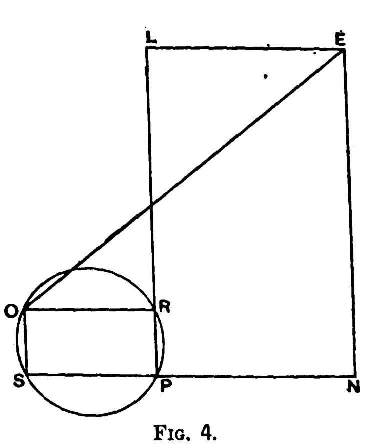

Fig. 4.

The following are two examples of this case worked out graphically.

(*a*) Two coils (100, 0·5), (100, 1), M = 0·6, are connected in parallel, and an alternating E.M.F. applied to their terminals, the frequency being 16 ($p = 100$) to find the currents, &c. Draw O R = 100 (Fig. 3), R L = 50, R P = 10. On O P as diameter describe a circle. Find the angle P O S by a construction as in Fig. 2. Make $SN = \frac{5}{2} SP$. Complete the parallelogram P L E N and join O E. Now make O E = 1,000; then O R = 100 $A_1 = 625$, &c.

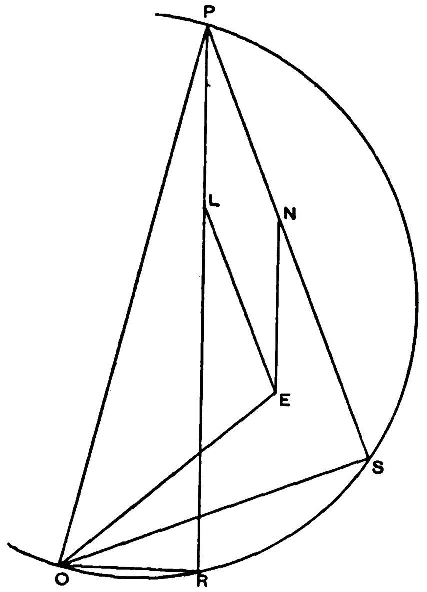

Fig. 5.

Hence $A_1 = 6·25$ and $A_2 = 5·83$ amperes. The angle E O R = the angle of lag of $A_1 = 38\frac{1}{2}$deg. $= \alpha$. The angle E O S = the angle of lag of $A_2 = 66$deg. $= \beta$.

(*b*) The frequency being increased to 80, in the last question, to find the currents.

The construction is shown in Fig. 4. We find

$$A_1 = 1·41,\ A_2 = 2·83,\ A = 3·16 \text{ amperes},$$
$$\alpha = 45°,\ \beta = 135°.$$

3. M negative.—The diagram for this case is shown in Fig. 5. It is easy to see that θ is zero when $p = 0$, and again when p = infinity; hence, for some value of the frequency, θ attains a maximum value. The diagram Fig. 5 is a worked-out numerical example for two coils (53, 0·29), (117, 0·18), and M = − 0·14, $p = 500$, V = 1,000 volts. We find that:

$$A_1 = 9·3, \quad A_2 = 10·2, \quad A = 19·2 \text{ amperes}.$$
$$\alpha = 40\text{deg.} \quad \beta = 18\text{deg.} \quad \text{Impedance} = 52 \text{ ohms}.$$

Prof. J. J. Thomson has solved the general problem in "Recent Researches in Electricity and Magnetism," Chapter VI. He explains the anomaly of circulating currents by dynamical principles as follows:—"The actual solution is that which makes the kinetic energy (of the loop) as small as possible, consistent with the condition that the algebraical sum of the currents should be equal to the current in the main." The following formulæ can be proved trigonometrically from the general diagram. (3) is also obvious from other considerations.

M < L and N or M negative.—θ is a maximum when

$$p^2 = \frac{RS}{(L-M)(N-M)}, \quad \ldots \quad (1)$$

M > L and < N.—θ is 90deg. when

$$p^2 = \frac{-RS}{(L-M)(N-M)}, \quad \ldots \quad (2)$$

$$\left. \begin{aligned} VA_1 \cos\alpha + VA_2 \cos\beta &= RA_1^2 + SA_2^2 \\ &= VA\cos\gamma \end{aligned} \right\} \quad \ldots \quad (3)$$

$$\left(\tan\alpha - \frac{pL}{R}\right)\left(\tan\beta - \frac{pN}{S}\right) = \frac{M^2p^2}{RS}, \quad \ldots \quad (4)$$

$$\frac{A_1^2}{A^2} = \frac{S^2 + p^2(N-M)^2}{(R+S)^2 + p^2(L+N-2M)^2}. \quad \ldots \quad (5)$$

Effective resistance—

$$= \frac{RS(R+S) + p^2\{R(N-M)^2 + S(L-M)^2\}}{(R+S)^2 + p^2(L+N-2M)^2}. \quad \ldots \quad (6)$$

Effective inductance—

$$= \frac{NR^2 + LS^2 + 2MRS + p^2(LN - M^2)(L+N-2M)}{(R+S)^2 + p^2(L+N-2M)^2}. \quad (7)$$

(Impedance)^2—

$$= \frac{R^2S^2 + p^2\{L^2S^2 + N^2R^2 + 2M^2RS\} + p^4(LN - M^2)^2}{(R+S)^2 + p^2(L+N-2M)^2}. \quad (8)$$

THE ELECTRICAL EQUIPMENT OF THE LIVERPOOL OVERHEAD RAILWAY.

BY THOMAS PARKER, M. INST. C.E.

(*Continued from page 579.*)

DISCUSSION.

Mr. S. B. Cottrell did not think he could add anything to the general description of the railway; but having had it under his observation during the first twelve months of its working, he might mention one or two points of interest. As had been stated, the only serious damage to the structure during the period mentioned was caused by fire. The conductor, as laid, had flexible copper connections at each joint, and as a result, a very considerable amount of creeping took place. The conductor was now coupled in lengths of 90ft. with rigid copper fish-plates, flexible expansion-joints being introduced at every third length; the creeping had entirely ceased and the conductor could be kept in very good line and level, whereas, before, foul joints continually occurred, and it was difficult to keep the conductor in line and level. During the first month or two short circuits occurred frequently, but now they very seldom happened; in fact, there had only been 19 since the beginning of 1894, each one of which was caused by the collecting-slippers touching the running rails when going through a cross-over road. The motors had come well up to the workshop tests. Only two of the whole number had required re-winding, and even then about 80 per cent. of the old coils were re-used. At first there was some little trouble with the brushes, the commutators frequently requiring to be skimmed up; but by a modification of the brush-holder that had been very much reduced. Originally the commutators required skimming up after running about 6,000 miles, but now they would run 9,500 miles, and one

Digitized by Google

had run 16,000 miles without skimming. The carbon brushes cost at first about £6 per week. That had been already reduced to £2. 10s., and it was hoped shortly to get it to £1 per week. The brushes used were flat carbon ones; round carbons had been tried and also copper gauze, but without success. The stations, as described, were lighted from accumulators; but during the winter months the accumulators were worked at very nearly their maximum output, in order to increase the life of the batteries; arrangements had therefore been made for lighting the stations by means of two sets of lamps, one in series off the main conductor, the other in parallel off the accumulators. An automatic switch was arranged so that, should a short circuit occur, the lights were automatically switched on to the accumulators. Of course, that meant some slight fluctuation in the light, but it was so trivial that it did not matter. The automatic signals were a new departure, but had answered admirably, effecting a very considerable saving in the working expenses. In the six months ending December 31st, the failure of signals to go to danger and to come off was 1 in 24,000 and 1 in 1,200 operations respectively. In the two months ending February 28th the signals had so much improved in working that failures were 1 in 212,000 and 1 in 2,000 operations, the cause of these failures in most cases being not electrical but mechanical. During the last two months he had gone very carefully into the cost of haulage, that was, since the Electric Construction Corporation had handed it over to his Company. With coal at the present price of 8s. 3d. per ton the haulage worked out at 3·48d. per train mile. With coal at its normal rate, as at the corresponding time last year, of 6s. per ton, it would only be 3·34d. per train-mile. Those figures included all wages, stores, &c., or, in other words, what came under the term of locomotive expenses. He entirely agreed with Sir Douglas Fox that for a traffic like that at Liverpool short trains at frequent intervals was the best system. Last August Bank Holiday 40,000 passengers were carried in about eight hours, and the platforms were never overcrowded. That was done by a three minutes' service of trains, and he had reason to hope that a three minutes' service would soon be required to deal with the regular daily traffic.

Mr. ALEXANDER SIEMENS noticed that several speakers had mentioned that it was a great advantage to have the motors on the cars, and not a separate locomotive. That matter had to be decided in each case on its particular merits; it could not possibly be universally true that a locomotive was the best, or that motors on the cars were the best. He might illustrate this by referring to Table A in the first Paper, where a comparison was given between the weights of motors and locomotives, which came out very much in favour of the motor system adopted in Liverpool. There were only two carriages, and, of course, the arrangements for working the two motors on the carriages from the one end or the other were comparatively simple. But the moment a railway was dealt with, where more carriages were wanted to run at the same time, the question of the switching arrangement was very serious. He did not know whether in most cases it would not preclude the use of motors on the carriages. In the same way, the multiplication of small motors on all the carriages meant a serious increase in cost, which, of course, was also not to be solved generally, but each case must be looked into. For instance, in Table A, the electric motors of the South London Railway, which had been made by his firm, did not weigh 10½ tons, but 13½ tons; they were 3 tons heavier than those of the Liverpool railway. On the other hand, those locomotives were powerful enough to draw at least two more carriages easily; though it could not be done on account of the accommodation for shunting in the City being insufficient. But supposing that five carriages were put on instead of three, the total weight of the train would be 45 tons, and the weight of the full train would be 802lb. per passenger against 871lb. in the Table, and against 752lb. for the Liverpool Overhead Railway. If the electric locomotives were properly used and fully utilised, the discrepancy was not so great as appeared in Table A of the first Paper. In Table B the "tractive force in lbs. per ton of train" was given as 120 for the 150-ampere motor on the Liverpool trains, and as 100 on the City and South London train. He wished to contrast that with the figures given by Mr. Preece, who stated that the locomotive at the Chicago Exhibition was giving a 6,000-lb. pull, and was meant for a 500-ton train. That was 12lb. per ton of train. Mr. Siemens had also been at Chicago. He did not see the actual trial of the locomotive, but the company were kind enough to give him some information; and, among other things, it was stated that the locomotive was capable of developing 500 B.H.P. at 30 miles per hour. As they proposed working with 500 volts, that would amount at least to 750 amperes of current. That was the mere electrical horse-power, no allowance being made for loss in friction or from other causes. To supply that current to the locomotive there was a single rod with an ordinary trolley wheel; but he was certain if 750 amperes ever attempted to get through those trolley wires the trolley wheels would melt away in no time. Great caution must therefore be exercised as to the importance to be attached to the figures given. It had been already pointed out by Mr. Preece why the experiments on the Elevated Railway in New York had failed. Mr. Siemens had had similar experience with that line. His firm, in 1881, offered to run one of the short lines by electricity, fitting up the line at their own expense, on the condition that, if it worked properly, they should have the fitting out of the whole system. It did not, however, suit the Stock Exchange in New York, and the offer was not accepted. Similar reasons appeared to have prevented the success of the experiments actually carried out. He was sorry to know that in the Liverpool power station the dynamos were driven by ropes instead of direct. He thought that double limb magnets were also a retrogression. There had been plenty of experience in 1885 of dynamos with double limb magnets of about the same size, and it was found that the horse-shoe magnet type was preferable in every way. In reference to experiments with ordinary drum-winding on the car, the author of the second Paper had stated that he found that the Eickemeyer winding was better. Mr. Siemens had wanted some idea as to how the motors of the two locomotives which their firm supplied to the City of London, acted, and he had received a letter from Mr. Mott, the resident engineer, stating—

"I have pleasure in sending you the following information, as requested:

					Miles.
"1. Loco. No. 16.	Total mileage to January 28, 1894			......	59,221
Loco. No. 15.	do.	do.	do.	......	49,580

"2. It has never been necessary to make any considerable repairs to these locomotives, except the alteration to the resistances which is now being done."

The second locomotive was delivered later than the other, hence the difference in the mileage. He did not believe there was a steam locomotive which had run close upon 60,000 miles without any repairs or alterations. The expense of brushes had been said by Mr. Cottrell to be £2 per week, but one of these locomotives had run with the same pair of brushes since it was delivered. He was rather astonished to hear Mr. Preece speak of hideous overhead wire and disparage it. He was always under the impression that the telegraphic wires were the great eyesore, and that if a line was properly put up, as, for instance, in South Staffordshire, it certainly was not such a frightful eyesore as Mr. Preece had tried to make out. Mr. Preece had also touched upon a point which he was afraid was greatly misunderstood. He had said that two amperes might career about Liverpool, eating away gas and water pipes. It was not the amperes that did anything. The possibility of pipes being damaged depended upon the pressure under which those amperes were sent about. If the difference of potential between the end of the line and the power-house was only 2 or 3 volts, 200 or 300 amperes might be about, and they would not damage a pipe. Of course they would interfere with telegraphs and telephones, but they could not do any damage to the pipes.

A great point was to be able to start an electric locomotive with less loss of energy than under the present system, where resistance was inserted at first, or other means were adopted; and he would suggest that a very good way, although it might not seem to be so at first, was to put on the locomotive a motor generator, and supply a high-pressure current from the power-house at 2,000 volts to the generator, and to put motors on the axles of the locomotive. That system, taking into consideration the cost of the conductors, the extra cost of the motor generator set, was not very much more expensive in capital outlay than the present plan of supplying a 500-volt current direct to the locomotive; but it did introduce additional complication; and, putting the whole arrangement into £ s. d., it would be found that the present system, although wasting a good deal of energy at the starting of the locomotive, was preferable, because it was simpler. He thought it was probably necessary to reassure the Dock Board about the sparks of the electric railway—that they were not of the same nature as sparks from a locomotive, where particles of carbon were flying about, which constituted a real danger to any inflammable substance that might be near. The sparks of an electric railway occurred near the rails, and were, of course, only particles of iron, which could not fly any great distance, and there was absolutely no danger whatever from them. Then there was a further interesting question touched upon by the author of the second Paper, who wished it to be believed that the mean efficiency from indicated horse-power to electrical horse-power on full load was 88 per cent. Only a few weeks ago, certain figures had been published about a direct-driven set which gave similar efficiencies, and they were promptly denied by "one who knew," who said that such efficiencies in steam engines and dynamos were simply impossible; and he certainly thought that, with the addition of the rope-driving, 88 per cent. was too high. On the other hand, he thought that, in the trial detailed, the author had hardly done himself justice, because if the figures given were compared with those which were attained on the City and South London Railway, and communicated to the British Association in 1892, it would be found that the average speed, including stops, which for the Overhead Railway was given as 12 3 miles per hour, was nearly

Digitized by Google

13 miles per hour on the City and South London. Then the average watts per train mile, the trains being about the same weight, were given in the Paper as 32,650; whereas on the City and South London line only 21,320 watts were used per train mile, which was a very great difference. He was sure there must be some mistake, because he could not imagine that the motors of the Liverpool line were so very much less efficient than those of the City and South London Railway. The great point for electrical traction was to have a frequent service. That was what had been pointed out as the reason why the average curves were much smoother the greater the number of trains there were; and, generally speaking, it could be laid down that where an electrical service was to be introduced on any line there ought to be frequent service; it was perfectly impossible to introduce electrical traction satisfactorily on railways where there were only three or four trains a day.

Mr. R. W. Blackwell had built that first road in America to which Mr. Preece had referred in 1884, and during the succeeding years, as electrical traction progressed, had to meet all those objections which had been mentioned with regard to the overhead wire. Throwing aside other questions, he would like to say a word in that regard. In America, between 1883 and 1890, it was said by every city, by every electrical company, by every tramway engineer, and by every æsthete, that an overhead line in a street was an abomination never to be tolerated, and should never be allowed under any circumstances. The consequence was that the pioneers of electrical traction in America began their work with the idea of perfecting the conduit system, which could be worked without the use of a visible conductor. They effected that result, and, when they did so, the cars ran fairly well; but when the question came to the financial test, and to the test of regular work, it was found that it cost approximately £7,000 a mile to put in a more or less efficient underground conductor, and that it cost about £700 a mile to put a first-rate, practicable conductor overhead. The reason why the overhead conductor had been adopted in the States had been simply that financial and practical reason. He thought everyone believed it was possible to make an underground conductor that would work; but nowhere had it, to the best of his knowledge, been made anything like a financial success, with the possible exception of that at Budapest. On the other hand, he believed it was absolutely demonstrated to the extent of some £30,000,000 invested in electric tramways in the United States, that every overhead trolley wire that had been erected had proved a financial success, had increased the dividends, and had served the purpose of the public in increased and more rapid transit. In the earlier days of electric traction elevated conductors were undoubtedly rude and unsightly in many cases; but so much attention had been paid to the elaboration and perfection of details of suspension and insulation that the trolley line of to-day was quite another thing. It seemed to him that such objections as might be urged against the aërial wire were vastly less important than those which were connected with any system that involved interference with the street surface and the maintenance of an open slot. Many great continental cities had lately adopted the trolley system, and, from a personal inspection of lines in Bremen, Hamburg, Brussels, Frankfort, and other towns, he was convinced that the method of construction there adopted left little to be dessired.

Mr. Stephen Sellon thought there was no necessity to go so far as the Niagara Railway in order to find a gradient of 1 in 20. There were plenty of tramways working at that gradient; for example, the electrical tramways at South Staffordshire and at Leeds, and the City and South London Railway. Referring to the abomination of the wires over the streets in Boston and other places, which made the overhead system so objectionable, the overhead wiring had been much modified to meet English ideas, and very little objection could be raised by anybody viewing the system as applied on the electric tramway in South Staffordshire, from a public road. In the American system, the trolley-arm worked from the centre of the car, which had no lateral movement; and therefore the conductor over the centre of the line was necessary. A large number of pull-over and span-wires had to be used for this purpose. In South Staffordshire a different kind of trolley-arm was adopted, having a radial motion enabling the conductor to be placed on a single row of poles alongside the road, dispensing altogether with any span or pull-over wires. The overhead system as there adopted showed a marked improvement upon the American principle; and it was not fair that the system should be condemned because in America an act of vandalism was committed in its application. Looking at the question of economy, he thought it would be absurd to suggest a conduit system in a district where it could not pay. Overhead installations, therefore, became necessary; and, no doubt, engineers in this country were quite able to reduce the objections, and not necessarily to have the overhead system as it was found in America. The remarks coming from Mr. Preece, the Chief Engineer to the Post Office, in objecting to he overhead system were somewhat extraordinary, as in Mr. Sellon's opinion it was no more objectionable to put up a few overhead wires, than it was to put up the usual structures of poles and innumerable wires that were seen along the whole of the roads in the country. It might be interesting to give a few figures in connection with the South Staffordshire tramways system, which was originally worked by steam, and of which eight miles were, in 1892, equipped with the overhead electric installation. While the line was working by steam, the gross earnings per car-mile reached the sum of 1s. 1½d., and the cost of working per car-mile was 1s., leaving a very short margin of profit. On the introduction of electrical traction in 1893, working expenses were reduced to 50 per cent. of the gross receipts. Referring again to Mr. Preece's remarks, that important body, the Joint Committee on Electric Powers Protective Clauses, had decided that railway companies, telephone companies, and gas and water companies should be called upon to protect themselves, so long as certain reasonable regulations (which regulations were not to place any restrictions on the commercial working of electric traction) were complied with; and from past experience he was sure that any serious conflict between the Post Office and any electrical traction installation, by which the Post Office might seek an injunction to stop the working of a tramway, would be due to the fact that the latter had not responded to the reasonable requirements nor to the well-known courtesy of the Chief Engineer to the Post Office. In conclusion, he would venture to express the opinion that the successful completion of the unique work described in the Paper was due to the fact that mere electrical theorists had had no part in the matter.

Mr. Alexander McDonnell was acquainted with the South Staffordshire tramways, and could see nothing, so far as the wires were concerned, in the least objectionable there. In the Paper, a comparison had been made between trains on the Liverpool Overhead Railway and on the Metropolitan Railway. Unfortunately the word "train-mile" was used a little too loosely. A train-mile, when comparing the expenses of one railway with another of similar traffic, or the expenses of the same line one year with another, was exceedingly useful—not perfect by any means, but still of very good practical use; but to compare a train weighing 38 tons and carrying 115 passengers with another train weighing 157 tons and carrying 400 passengers was going too far. The system of electrical traction upon the Liverpool Overhead Railway was exceedingly well adapted for the trains and traffic there; but for such a line as the District or the Metropolitan Railway, with the traffic on them, it would be found that it was not adapted in any way, so far as was known at present. Where there was a system of trains running at intervals of three to four minutes, electric traction was tolerably economical; and, taking the District system, where between the Mansion House and Victoria there was a three or four-minute service, supposing the electric traction was sufficiently powerful to deal with a train of 150 tons, there might be economy; but when places like Wimbledon, Ealing, Willesden and Richmond were considered, where there was a half-hourly service of trains, it certainly would not be economical. Electric traction seemed very good where there was a fairly developed traffic of light trains running very often; but it certainly was not at all suitable for developing traffic on a railway of light traffic. In the case of a tramway, traffic must be developed by horse traction or locomotive traction, and when it was developed electric traction might be useful; but to lay down the whole of an electric system, with its fixed plant, for a tramway system with cars running every 20min. or 30min. would certainly not be economical, although it might be economical in a 3 or 4 minutes' service. It was stated that the locomotives on the overhead system in New York burned 54lb. of coal per train-mile for trains of about 92 tons weight. Upon an ordinary branch line a train would have about five carriages, weighing about 50 tons, and a tank-locomotive of probably about 45 tons, making 95 tons altogether. Such a train would seat about 200 passengers if full, which of course it never was. A locomotive would work that for about 18lb. of coal a mile, so that 54lb. was to him quite unintelligible. The cost of working such a train by locomotive power would be about 6d. a mile. It was stated that the electric traction cost about 4d. a mile when the trains were run frequently; but the authors had omitted to take into account the depreciation and renewal of stock. The 6d. a mile that Mr. McDonnell was speaking about included everything—drivers, coals, ordinary repairs and renewals. He expected that in electric traction the depreciation would be considerable—that the life of a great part of the stock would be very short. Of course, the life of the fixed plant, stationary engines, and so on, would be long; but the motors and things of that sort would in all probability be short-lived, and to that 4d. a mile the depreciation should be added. To suppose for one moment that, because the electric system was good and economical upon a railway such as that described in the Paper, it could be used for anything like an ordinary railway system was quite beyond his comprehension. For a railway such as the London and North-Western, with trains varying between 80 tons

Digitized by Google

and 500 tons in weight, and with speeds varying between 20 miles and 60 miles an hour, the system was not adapted, and any kind of comparison made between them could not be fair. Without in any way suggesting that the system adopted on the Overhead Railway at Liverpool was not exceedingly well adapted there, he considered that it was not at present suitable for other railways, not even the most similar in kind—namely, the Metropolitan.

Mr. W. WORBY BEAUMONT wished, first, to ask the authors if there was any reason, other than that stated in the Paper, why the plates forming the flooring of the viaduct were bent hot, and if they could not have been put in cold. He was under the impression that a machine might have been made at no great cost which would have bent the plates cold at a low cost compared with the expenditure in bending them hot. Another point was the one on which Mr. Trotter had remarked, with reference particularly to some of the diagrams. It was known that for the working of any set of machinery, or for any electrical installation, the load factor might be said to give an indication of the expenses and of the profit that might be obtained at any particular time. The diagrams shown accentuated the remarks, he thought, made by Mr. Greathead on previous occasions as to the great cost at present incurred in getting a train into motion electrically and also in shunting operations, as, for instance, on the City and South London Railway. He thought it might be shown that to a very large extent that waste might be avoided. Taking a datum line as in the diagrams given in the Proceedings Inst. C.E., Vol. CXII., pp. 246, 247, it was found in almost all cases that the diagram representing the power taken in getting an electrically moved train into motion was of the character referred to by Mr. Trotter. As soon as the train had fairly started, the time occupied being, as shown by some of the diagrams, only from 10sec. to 15sec., the power taken fell to about one-half; it was of various heights further on until a stop was reached, and again this was repeated. It was not only that the power as compared with that taken by the steam-locomotive to get the train into motion was, for the greater part, waste power; but it meant that the power which must be available at the central station must be that represented by the full height of the power diagram. It was not that a mean load had to be available, but that at any moment the power represented by that full height must be available, the engines running for that purpose. Of course, the power was not always used, and the engines, and particularly the boilers, were working at a great disadvantage; because, although that power was not taken, it must be ready to be supplied at any moment. He had shown on a previous occasion that it would be possible by mechanical means to avoid taking more power than was necessary for keeping the train in motion. Mr. Siemens had mentioned a method of getting over that difficulty electrically, and had explained why it was bad or insufficient; and, having proved that it was not satisfactory, had said it was better to waste the small amount of power shown between the two lines midway on the top of that diagram, rather than to use a method which he had said was not a good one. That, therefore, could hardly be said to have been of assistance with regard to this problem; and although on several occasions it had been mentioned that electrical methods might be adopted, it had not, he believed, been shown that electrical methods could be used which would avoid the necessity for a great deal more power than would be required by a locomotive engine in moving its train. As Mr. Trotter had pointed out, until a train was actually in motion, or so long as the locomotive engine was getting it into motion, it was actually doing little work, and the steam was only used in that degree. To get over the difficulty, two motors might be coupled as on the Elevated Railway, in series, getting the train more rapidly into motion and avoiding some of the electrical difficulties that would otherwise occur; but, at the same time, the power required for getting the train into motion within a given time was just as great as if the motors were in parallel. As far as was yet known, electrical methods could not be said to be satisfactory for surmounting that difficulty; but it could be got over mechanically, and it only remained for engineers to adopt the methods that had previously been pointed out.

Dr. EDWARD HOPKINSON, in offering a few criticisms upon the second Paper, did not wish it to be supposed for a moment that his object was to detract from the excellent results achieved. Those results were most striking, but, at the same time, some statements had been made which appeared to him to be open to very serious exception. With regard to the question of efficiency of engines and dynamos at the generating station, the author had given the electrical efficiency of the generating dynamos as 97·7 per cent. That, no doubt, could be attained in well-constructed machines, and fairly represented the electrical efficiency at Liverpool. But the author had gone on to say that the efficiency, as between the I.H.P. in the cylinders of the steam-engines and the electrical H.P. as delivered from the terminals of the dynamos, was 88 per cent. Anyone who had experience of the frictional diagrams of large steam-engines, and especially the friction caused by rope-driving, would recognise in that a very startling result, and one that he was not at all prepared to accept. Perhaps the highest efficiency ever realised as between electrical H.P. and I.H.P. had been obtained with a Willans engine. Everyone who was familiar with that engine would state from the perfection of workmanship exhibited, that the friction must be exceedingly low; and yet the best results ever obtained by Mr. Willans with a great variety of dynamos by the best known makers had never exceeded 87 per cent. The efficiency was usually 85 to 87 per cent., and the few results obtained above 86 per cent. were, it would be admitted, probably due to the fortuitous concurrence of various small sources of error, which happened to run together in a favourable direction. Taking the author's figure of 88 per cent., and the electrical efficiency at 97·7 per cent., it meant the loss in friction of engine, ropes and dynamo, and by electrical friction of various kinds in the armature, was only 10 per cent. Such a result all who had any experience of rope-driving would at once say was absolutely impossible; in fact, before it could be accepted, the author would naturally be asked to give the friction-diagrams of engines only, the friction-diagrams of engines and ropes, and finally the friction-diagrams of engines and dynamos running without load. The motors were, no doubt, the most important and the most difficult point to deal with in traction work. The armature-resistance of each motor was given as 0·67 ohm, and the magnet-resistance as 0·37 ohm, making a total of 1·04 ohm. When the motors were in series, as at starting, the current was about 130 amperes. Doubling the resistance for two motors the result was 2·08 ohms., which, multiplied by 130, gave the loss in volts at 270. Therefore, the electrical efficiency of the motors throughout the early part of the run up to the point at which the two motors were placed in parallel, was 44 per cent.; after they were placed in parallel, with a current of 90 amperes, the efficiency was of course improved, but still did not reach more than 80 per cent. He was very far from saying—in fact, quite the reverse—that the author had been wrong in designing the motor with a large number of convolutions on the armature in order to have a very high resistance, and consequently exceedingly low electrical efficiency with a heavy load. It was known that if the spare electromotive force at starting was not absorbed in the armature and the magnet coils it must be absorbed in the external resistance. He mentioned this simply to draw attention to the fact that these motors at that period of their running had this extremely low efficiency, and to show the direction in which better results might be obtained in the future. In remarking upon a Paper* which Dr. Hopkinson had read before the Institution last year, the author had given the resistance of the City and South London motors at figures about one-third the resistance of the Liverpool Overhead Railway motors. Their power was about the same; but the author, by putting more convolutions on, absorbed the power in the motors instead of in the external resistance. To effect that, the device of putting the motors first in series and afterwards in parallel had been adopted. In that the author had done right; but it would only have been proper on his part if he had acknowledged to whom that device was due. It was due, as a matter of fact, to Dr. John Hopkinson, but had been taken up by the late Sir William Siemens more than ten years ago. Here, again, it was matter of regret that the author, in describing the motors, and especially the system of direct driving, should not have thought it necessary to refer to what had been done previously in that direction, and more particularly to the work of the late Sir William Siemens. Electrical engineers had not advanced so far in traction work that they could yet afford to ignore the pregnant suggestions made by Sir William Siemens at a time when the subject was in its infancy. For the same reason, he would notice that the form of conductor and the method of supporting and insulating it were exactly the same as had been adopted on the City and South London Railway; but of that he had no reason to complain, as imitation was not uncomplimentary. The most important point in the Paper was the statement that the tractive force of each motor was 1,450lb. with 100 amperes. In discussing Dr. E. Hopkinson's Paper last year, the author had given 1,450lb. as the tractive force of two motors.

Mr. PARKER: One motor.

Dr. E. HOPKINSON said, taking the figures as applying to one motor and following out the results, if the author had given the number of convolutions of the armature and the number of lines of force, not through the magnet but through the armature, the tractive force with any current could be at once determined; but this he had not done, and the result must be judged by the subsequent part of the Paper. It appeared, as far as could be judged from the small-scale diagrams appended to the Paper, that the mean current during the time of running was 110 amperes; that for one-fifth of the time the current was 100 amperes with the motors in series; for three-fifths of the time it was 150 amperes with the motors in parallel; and for one-fifth of the time it was cut off altogether, thus giving the mean current 110 amperes

* Minutes of Proceedings Inst. C.E., Vol. CXII., pp. 209 *et seq.*

Digitized by Google

while the current was on, which agreed with the Author's result of 90 amperes while running. Taking the curve of tractive force and current and deducing therefrom the tractive force corresponding with the currents given in the Paper, this extraordinary result followed; that the average tractive force per ton of train was 55lb. It had been ascertained that on the City and South London Railway the average tractive force was 13lb. per ton of train. There was therefore the extraordinary discrepancy between 13lb. and 55lb. per ton for trains weighing practically the same, and working under much the same conditions. From the work done by this 55lb. per ton of tractive force, must be deducted the energy which was required to give the train its velocity. The total amount of work done in one section of the line of average length was 3,521,000 foot pounds, and the energy required to give a train of 39 tons a velocity of 21 miles per hour was 1,295,000 foot pounds. Hence, deducting this amount, which of course it was proper to do, the final result was that the tractive force required to work the trains on the Liverpool Overhead Railway was 35lb. per ton, *i.e.*, the force required to overcome the resistance only and not to give the train acceleration. That was a result much more than double the figure previously given for the City and South London Railway, and also greatly in excess of common experience. There were therefore good grounds for expressing the opinion that the Author had made the mistake of confusing the tractive force of one motor and of two motors; and that affected the comparison instituted by Mr. Greathead and by Sir Douglas Fox between electric and steam traction.

All systems of traction must be finally judged by the cost at which the service required was provided, and in that respect excellent results had been obtained at Liverpool. It was interesting to observe that, when local circumstances were taken into account, the results were almost identical with those obtained on the City and South London line as ascertained from the balance sheet for the half-year ending December 31, 1893. The weight of the trains and the speeds attained were about the same, but on the City and South London line there were somewhat steeper gradients and sharper curves, and the railway was in tunnels; on the other hand, at Liverpool there were somewhat more frequent stops. The total cost of traction on the Liverpool Overhead line, including current supplied for signalling and lighting, was 3·975d. per mile, with coal at about 55·10d. per ton; whereas, on the City and South London line, including current for lighting but not signalling, it was 6·22d. per train-mile with coal at about three times the price for the same calorific value, and a higher rates of wages obtaining. If the coal in the two cases had cost the same, the City and South London cost would have been 4·9d. per train-mile. It might, therefore, be taken as proved beyond doubt that such railways could be worked electrically at a cost for motive power of 4d. to 6d. per train-mile, according to the price of coal. But these results would undoubtedly be further improved upon in the future. On the Liverpool Overhead line the repairs amounted to 0·95d. per train-mile, whereas on the City and South London line, which had the advantage of having been working for three years, and therefore was in all its parts thoroughly well tested, the cost of repairs of all descriptions was only 0·7d. per train-mile; in fact, he had been recently informed by the engineer of the railway that many of the locomotives had now run over 100,000 miles, and that the cost of repairs upon them during the last 30,000 miles had not exceeded 0·03d. per train-mile.

Mr. T. Parker, in reply to the discussion, referring to Mr. Hedges' remarks on the Niagara Falls Electric Railway, compared it with the overhead wire system of tramways in South Staffordshire. On the latter line, the gradients reached as high as 1 in 16, sharp curves occurring upon some of them. The cost of working this system (each car carrying 34 passengers, being equipped with two motors, and weighing, without passengers, about 6¾ tons), during the six months ending December 31, 1893, including car drivers' wages, maintenance of generating plant, car motors, feeders, trolley wires and superintendence, was 4·16d. per car-mile. In the case of the Blackpool tramways, for which the Author designed the dynamos and motors, the cost of running during the year 1891 amounted to 3¾d. per car-mile, this amount including costs usually charged to haulage, but exclusive of traffic expenses, repairs to permanent way, and general management expenses. It had many mechanical and electrical defects in the method of conveying and collecting the current. In the Madras tramways, with which he was now engaged, the slot was not in the centre of the road as at Blackpool, but in the groove of one of the rails, and ¾in. wide. The difficulty of securing satisfactory collection from underneath the road through the slot and past the points, had previously prevented that mode of slot from being brought into use, but he had now surmounted those difficulties, at a cost of about £1,600 per mile over ordinary road.

The great amount of power required in starting the trains on the City and South London line had been pointed out by Mr. Trotter, and upon that point he would refer him to Fig. 7., p. 554, *ante*, which showed that the trains at Liverpool required less energy at starting than when in motion, and the advantage of placing motors in series for starting and afterwards in parallel. Attention had been directed by Mr. Preece to the rope-driving used at Liverpool, and in reply to his remarks, Mr. Parker could only state that he had most careful tests carried out, and had submitted them to the Institution in all good faith. The data used in comparing those tests was taken chiefly from high-speed engines and direct driving; and there was no definite proof that high-speed rapidly-reciprocating engines did not absorb as much power in arresting and accelerating their parts as was required to drive ropes arranged as at Liverpool. With regard to electrical leakage, the Liverpool Overhead Railway was very favourably situated, as the iron structure afforded an easy return for straying currents. The point to be considered was whether the progress of electrical engineering should be retarded by the telephones and telegraphs claiming to remain monopolists, or whether the necessary modifications should be made to enable them to work side by side with other electrical enterprises. It was highly satisfactory to him to hear Mr. Cottrell speak in such terms of the railway, and state that he had been able to reduce the cost to 3·34d. per train-mile. The arrangement of the switches on the motor cars had not been discussed. It was such that when the brake was applied the switches immediately flew out and cut off the current from the train.

In comparing the energy used on the City and South London line with that used on the Liverpool Overhead Railway, Mr. Siemens had not given the whole data. The trains at Liverpool were 12 per cent. heavier, ran at an average speed 24 per cent. greater, and made an average of 50 per cent. more stops in the same distance; therefore comparison of energy used was misleading, unless those features were considered. Mr. McDonnell had stated that the trains at Liverpool were suitable for the Overhead Railway, because they ran at short intervals and were small trains, but would not be adapted to the District or the Metropolitan Railway. There was no difficulty in running heavy trains at short intervals on the Metropolitan Railway, as the light trains were run at short intervals in Liverpool, and with the same proportionate economy, with all the advantages of cleanliness and freedom from combustible gases in the tunnel. In comparing a branch-line locomotive for coal used, it did not appear that Mr. McDonnell had taken into consideration the high speed and number of stops on the Liverpool Overhead Railway. In stating the costs of working, there had been no omission to take into account the depreciation and renewal of stock, as that was part of the contract with the Liverpool Overhead Railway. With respect to the life of the dynamos and electric motors, he had no hesitation in stating that the depreciation would be found to be less than with steam engines, and they were much more easily renewed and repaired. He asserted that the electric system of traction was thoroughly suitable for the Metropolitan Railway, and superior in every respect to the locomotives in use. In discussing mechanical appliances for tramways, to enable motors to be run at constant speed, Mr. Beaumont had dealt with a subject that had engaged much attention; but the difficulty of getting mechanism of any kind to work in the space available, and yet have a reasonable life, had not been surmounted.

The efficiency, 88 per cent., between I.H.P. in the cylinders and power delivered at the dynamos, had been questioned by Dr. E. Hopkinson. This Mr. Parker had referred to in replying to Mr. Preece. The tractive force on the City and South London line with a current of 150 amperes was given by Dr. Hopkinson as 50lb. per ton of train. The motors at Liverpool with the same current gave a tractive force of 120lb. per ton of train; so it would appear that the motor at Liverpool would start a train twice as heavy with the same current, or be in the same degree more powerful to accelerate the load. A motor must be judged by the manner in which it served the purpose for which it was built. In words Dr. Hopkinson had admitted that the motors were rightly designed, yet had condemned them by figures. The figures would perhaps be correct if the motor ran at a constant speed, but where it was necessary for motors to be constantly starting and accelerating as at Liverpool, the figures given by Dr. Hopkinson did not apply.

Mr. Greathead, in reply, observed that no criticism had been made in reference to the structure, and he would therefore say a few words about other matters. He had hoped more would have been said on behalf of steam locomotives. Astonishment had been expressed by Mr. McDonnell at the high coal consumption on the Manhattan Railway, 54lb. per train-mile, as compared with the coal consumption on a small branch line in England; but he had overlooked one very important factor, viz., the distance between the stations. That had a most important effect upon the coal consumption of a railway. He had the curiosity a few days ago to calculate what the coal consumption would be upon the inner circle of the Metropolitan Railway if the stations, instead of being on an average half a mile apart, were one-third of a mile apart, and found that to obtain the same speed the coal consumption would be almost doubled. On the Manhattan Railway the stations were about one-third of a mile apart, and the coal consumption was not

Digitized by Google

excessive for the work the locomotives were doing. Reference had been made to the leakage of 2 or 3 amperes at Liverpool. It was often difficult to determine whether Mr. Preece was serious in making his remarks. Those remarks were made gravely, almost solemnly, but Mr. Greathead concluded from the fact that the Company had never heard anything from the Post Office, that they were not really serious. The leakage of current from the main conductor would readily find its way along the iron structure, and would probably none of it reach the earth. In reference to what Mr. Siemens had said, as to the currents required for the motors at Liverpool compared with those required for the experiments on his locomotives, it might be interesting to give some figures as to the actual current employed in working the two railways. He found at Liverpool, taking the output of the generating station and the train-miles as the basis of calculation, that during January and February each train on an average took 36½ E.H.P. On the City and South London Railway, where the speed and the weight of train were about the same, the average power taken was 33 E.H.P. per train; so that in the actual work there was very little difference. But in the case of the Liverpool line, there were included in the demands upon the current the working of the brakes, the working of the automatic signals and of the tools at the shop, and also the lighting of the generating station, the stations, and the trains. Further, the trains had to make a great many more stops, the average distance between the stations on the City and South London Railway being about 1,100 yards, while on the Liverpool Overhead Railway it was only 750 yards. On the former line, the lighting of the trains and stations was included, and formed, of course, a larger portion of the whole than at Liverpool, the lights being required throughout the day's working.

CORRESPONDENCE.

Mr. JOHN A. F. ASPINALL thought it had been attempted to compare to a certain extent the working of an electric line with an ordinary railway worked by locomotives, somewhat to the disadvantage of the latter, and that it would be well in the early stage of such comparisons to put the figures upon a proper footing. The working expenses for motive power had been stated in the Paper to be about 4d. per train-mile, and the consumption of fuel at about 16lb. per train-mile for trains of about 38 tons weight, running at 12 miles per hour; and those figures were compared with statistics of the New York Elevated Railway, where 54lb. of coal were used per train-mile. If the comparison was to be a fair one, electrical railways, such as had hitherto been constructed in England, should not use the train-mile as the divisor for the figures of the main lines of the country. When dealing with railways worked by locomotives, the engine-mile was the only figure which could be applied in order to put the comparison upon a proper basis. In order to explain this, if an ordinary railway had 1,000 engines, it was quite possible that 300 of them might never run a train-mile, but might be employed dailing in shunting and marshalling heavy loads, pulling them in and out of sidings, and adding to the expenses of the locomotive department as a whole without increasing the divisor, as the mileage run in that case was called engine-mileage and not train-mileage. If the engine-mileage figure of ordinary railways were taken, it would be found that one at least of the largest railways in Great Britain was able to do all that additional work and to run very heavy goods trains, entailing considerable expenditure, at a figure slightly exceeding 6d. per engine-mile, including the amount required for the maintenance and the renewal of the whole of its stock; whereas, the 4d. per train-mile spoken of as being the cost on the electrical railway did not include any sum for renewals of stock, which, sooner or later, would have to be provided. If the amount shown in the half-yearly accounts of the Liverpool Overhead Railway as having been spent on working stock and generating stations—namely, £73,744—were taken as a fair figure, it was evident to any one familiar with the subject that a proper provision for the renewal of plant would require an expenditure of about 2d. per train-mile, which would make the cost for locomotive power on the Liverpool Overhead Railway about equivalent to that of working any ordinary light railway. To confirm these figures, he would refer to the Paper* on the City and South London Railway, by Dr. Edward Hopkinson, in which the cost of working that line in several half-years was given, showing that the locomotive expenses varied from 9·1d. at first to 7·1d. in the half-year ended December, 1892. So far as appeared in the Paper, even those figures did not include any sum reserved to meet the depreciation of the plant. With regard to the consumption of coal, he would ask why the authors had gone to New York to ascertain what a locomotive consumed in doing a given amount of work? There was no first-class railway in England that Mr. Aspinall knew which consumed more than an average of 41lb. of coal per engine-mile, which included the consumption for its heaviest goods and passenger work; but the work done by these electrical railways was not heavy but extremely light, and, even if compared with the work done by any of the express trains between London and the North, the consumption of coal did not show very favourably. He noticed that Mr. Parker had stated in the second Paper that the consumption of coal was 22½lb. per train-mile during April and May, and that it was only during August that the 16lb. was approached. If the authors had been anxious to ascertain what a locomotive dealing with suburban traffic consumed, they need only refer to Mr. Stroudley's Paper of ten years ago, where they would find that his four-wheel coupled tank-engine was doing the work with a load stated in the Paper at a consumption of about 16lb. of coal per mile. He laid special stress upon this matter, because if a comparison was to be made about fuel consumption, it should be made with English railways and not with American, where but little care was taken about economy in fuel, possibly because the price of coal was about one-half that in England.

* *Minutes of Proceedings* Inst. C.E., Vol. CXII., p. 209.

The selection of the Metropolitan District in Table B, or even the Great Northern suburban train in Table A of the first Paper, was not a happy one; as he had not the slightest doubt that the Liverpool Overhead Railway, with its easy gradients and curves, its low speed and light trains, could be well worked by properly-designed locomotives at a cost of something under 6d. per mile, including all charges for running and for the maintenance and depreciation of locomotive stock, if the drawback of the possibility of sparks and smoke was not considered.

In reference to the design of the carriages, he must express surprise that after the careful examination that had been made of the elevated railways of New York, cars constructed like those described in the Paper should have been put upon the Liverpool Overhead Railway, as one of the most striking things on the elevated railway in New York was the way in which the cars were rapidly filled or emptied by the central passages and end platforms. In the Liverpool cars side doors had been constructed, which were inconvenient, with the further objection that, when they were opened on entering a station, they tended to sweep the narrow platforms. As to the construction of the ironwork of the viaduct, and the bridges on the railway, he had nothing but admiration for the simplicity and neatness of the design, and would say that the machinery for bending and drilling the plates was both well designed for its work and of the simplest possible character.

Mr. R. E. CROMPTON congratulated the author of the second Paper on having obtained a very high economical efficiency from the boilers, engines and dynamos; but he had given the electrical horse-power at the terminals as 88 per cent. of the horse-power in the cylinders, a figure which Mr. Crompton believed to be impossible under the circumstances. He had no doubt the author had obtained a very high figure; but would show that the efficiency mentioned must be considerably below 88 per cent., when rope-driven sets, such as those described were used. The Sulzer engines made by Messrs. Carels, of Ghent, had the best reputation for high mechanical efficiency on the Continent of Europe. Having made careful inquiries, he had found that those manufacturers rarely succeeded in obtaining an engine efficiency exceeding 90 per cent., and that they were doubtful whether 91 per cent. had ever been recorded with a condensing engine, which must include the friction of the air pump, &c. If it were supposed that Messrs. Musgraves' engines were as efficient as those of the Sulzer type, and if 2 per cent. at the dynamo-pulley only were allowed as the loss in the rope drive, the result was 88 per cent., which was the figure claimed by the author at the terminals of the dynamo after all the mechanical and electrical losses of the dynamo had been taken into account. It was true that the author claimed an electrical efficiency of 97·7 for the dynamos, so that it was possible, if they were direct-driven, and the bearings were thus relieved from the side stress, that they might have a commercial efficiency of 96 per cent.; but a long series of experiments made by Mr. Crompton at Chelmsford had shown him that when dynamos were driven by ropes or belts so that there was side stress on the bearings, a commercial efficiency exceeding 95 per cent. could not be obtained; 95 per cent. of 88 per cent. was about 84 per cent., and that in all probability would be found to be the maximum efficiency actually obtained when the author repeated his experiments with carefully calibrated instruments. On the excellent evaporative result he had obtained from the boilers when burning small Lancashire slack the author was to be specially congratulated, having effected results not hitherto attained in electrical works using that class of fuel. The coal consumed per kilowatt hour for the month of September was exceptionally low, and compared favourably with the best figures obtained in any electric lighting station, the only one approaching it being that of the Kensington station in London, which used 4·95lb. of Welsh coal per kilowatt-hour.

(To be concluded.)

Electric Locomotives.—The well known Baldwin Locomotive Works at Philadephia have just completed their first electric locomotive.

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; and Dr. Heinrich Hertz, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar of Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

GAS TRACTION AT BLACKPOOL.

We do not know whether it is consistent with the dignity of a President of an Engineering Society to chuckle; but, if it be so, we feel sure that the President of the Institution of Mechanical Engineers must have so far indulged himself on receipt of the prospectus of the Blackpool, St. Anne's and Lytham Tramway Company. Was it not but five short months ago that he ventured to depart from the usual dull groove and impart a little wholesome criticism of engineering methods into a Presidential Address, and by so doing did he not draw down upon him the anathema of electric traction men because he pointed out the obvious fact that directness, at any rate, is not one of the advantages of electric traction, and because, looking at the matter from this point of view, he was sanguine of the "ultimate possibilities" of self-contained gas-motor cars? To-day we have a line, which most of us hoped would have added at least another eight miles to the present meagre total of electric tramway mileage in the United Kingdom, adopting Lührig gas-motor cars.

Nevertheless, we do not think that the electric motor car is in consequence about to be relegated to the scrap-heap, or even to a back seat. The line which is in contemplation is very level throughout; it runs along a breezy sea front, and those who travel by it will consist mainly of holiday-makers, volunteers, and golfers, none of whom are likely to prove over particular with regard to such disagreeables as smell, heat, and noise. If gas traction is in reality destined to prove a formidable rival to electric traction, it will have to

Digitized by Google

contend with electricity not merely under the highly favourable conditions which obtain at Blackpool, but in narrow streets, where no sea-breeze assists in the deodorisation of the stuffy thoroughfares, where travellers are a trifle exacting, and not likely to look favourably upon a box-full of small nuisances, and where it is not usually a case of Hobson's choice, as it will be at Blackpool. If the public gladly suffer gas-motor cars at Blackpool, it will be time enough for makers of electric motors to prepare to meet a serious rival.

From the mere engineer's point of view a reduction in the number of transformations of energy, and a saving of a certain percentage in operating expenses are great accomplishments, but in tramway matters it is not so much cheap traction as comfort and convenience that win the day. And in these respects the gas-motor car leaves very much to be desired. It is the public, not the engineer, who ultimately decides the question. Coming, however, to the question of cost, electricity may be relied upon to hold its own. A comparison between the working of an undertaking like the Liverpool Overhead Railway with the running of a lot of little tramcars may, at first sight, appear greatly out of proportion. The cases are altogether so different, it may be said. On the one hand there is a train, consisting of three or more heavy coaches, and capable of carrying nearly a hundred passengers; and, on the other hand, there is a single car, the maximum carrying capacity of which does not exceed forty persons. But what if it is found that the expenses involved in running the heavy train a mile are little more than 20 per cent. greater than the sum it is proposed to pay for conveying the light car a similar distance? It has been arranged that the Blackpool-Lytham tramway shall be run by a syndicate, for seven years, for a sum of 4½d. per car-mile, with a minimum of 163,000 car-miles per annum. The contractors for the electrical equipment of the Liverpool Overhead Railway found that they could make a handsome profit out of their arrangement to run the railway for 4d. per train-mile; and that railway is now being run at a cost of about 3½d. per train mile. Adding to this last-named sum the charges which are necessary in order to make the two cases cover as nearly as may be the same items of expense, it will be found that the relative costs stand at 5½d. per train-mile at Liverpool, as against the proposed 4½d. per car-mile at Blackpool. When the comparisons are based upon the costs per possible passenger-mile or per ton-mile, they show even more favourably on the side of electric traction. It is conceivable, of course, that 4½d. represents a sum hugely greater than the actual cost of running a gas car; but we do not think it probable that this is so. Commercial considerations would conflict with any temptation to try and reap gigantic profits in the case of so novel a project; and it seems likely that the figure covers no more than the working expenses and a reasonable profit. But electricity need not, as a matter of fact, go so far afield as Liverpool to be justified of her children. The historic Holroyd Smith electric tramway at Blackpool itself, pioneer concern as it was, cost, on the same basis as that upon which the Blackpool gas-motor contract has been made, only 2¾d. per car-mile to run, and that on such a diminutive mileage as 98,000. An electrical syndicate, therefore, might well have made a seven years' contract for less than 4½d. per car-mile, and withal have reaped the reward of conscious merit and of an excellent bargain.

This being the case, we hold to the belief that there remains yet a great deal to be done before gas traction can assume a formidable rivalry with electric traction. Gas traction may, of course, be vastly improved in time; but so will its electrical competitor.

THE CHEMICAL THEORY OF ACCUMULATORS.—I.

BY E. J. WADE.

The reversibility of the primary or ordinary galvanic cell, as embodied in the secondary or storage cell, is but one more example of the universal law of action and reaction. Hardly had the voltaic pile been invented before it was discovered that when at work it developed some resisting or opposing force, which tended to choke down the flow of current; and, further, if it were connected to a pair of metal plates or wires dipping into some saline conducting liquid, these latter themselves acquired the power of giving a momentary current after disconnecting from the pile. Gautherot first observed this phenomenon in 1801 while decomposing salt water with wires of silver and platinum. Two years later Ritter obtained the same effects with gold wires, noticed the formation of metallic films and peroxides by electrolytic action, and embodied the results of his observations in his secondary pile, which consisted of discs of copper separated by pads moistened with saline solutions, and which, when charged up by a battery composed of a larger number of elements than itself, could give out transitory currents of considerable intensity. These secondary currents were rightly thought to be due to the recombination of the acids and bases set free when the salts were decomposed by the passage of the primary current. Some years later, however, it was observed that similar currents could be obtained from platinum wires which had been used to decompose dilute sulphuric acid, or even pure water, and as in this case the metal was not oxidised, and there were no salts present to be decomposed, it was maintained that they must have a physical rather than a chemical origin, and the wires were said to be "polarised," while the phenomenon itself was termed "polarisation." During the years that followed numerous investigators were constantly at work on the subject, but nearly all from the same point of view, and with the same object. They regarded polarisation effects as of no value in themselves, but studied them in order the better to be able to destroy or reduce them to a minimum, and so increase the efficiency of primary cells, and it was during this period that the Daniell, Grove, Bunsen, and other constant current batteries were invented. It was conclusively proved, however, that polarisation was always due to purely chemical causes, and in the cases just mentioned was caused by the decomposition of the water itself into its constituent gases, which were liberated at either pole, and generated secondary currents during their recombination. Platinum wires, which had been immersed in oxygen and hydrogen gas respectively, gave currents in dilute acid just the same as those which had had a primary current passed through them, and Sir W. Grove constructed his well-known gas battery, which he described in 1842, on this principle. Although Grove set up his battery by the addition of oxygen and hydrogen previously prepared, he could, as he well knew, have energised it equally well by sending a current through it and decomposing the water, and it may be considered, therefore, as the earliest form of reversible battery which was fully recognised as such. In fact, no storage cells of more recent date present the principle on which their action depends in a simpler or more striking form than does this gas cell of Grove, and besides which it embodies some of the chief points that go to the making of a good accumulator in such a complete manner that, although practical difficulties stand in the way of its adaptation commercially, it will always possess a very considerable theoretical interest.

The line of research, however, that it might naturally be thought to have suggested was not followed up, because in those days the need of a cell for the storage of electricity was not felt, and even if one had been invented it could have been of very little use. Primary cells were then the only known source of dynamic electricity on any practical scale, and to have set up a number of these merely to charge a smaller number of accumulators, instead of using them direct for the purpose in view, would obviously only have been a waste of both labour and material.

Gaston Planté was the first to investigate polarisation phenomena with a view to their utilisation instead of their elimination, and in 1859 he commenced the series of researches

Digitized by Google

which are embodied in his well-known work. The experiments he carried out, and the apparatus he employed, were of the very simplest nature. Rods of various metals were in turn placed in a small acid voltameter or electrolytic cell, and a current passed through it from two or three Bunsen cells; then, by means of a simple form of mercury switch, the battery was cut out of the circuit, and the voltameter at once connected to a sensitive galvanometer. In this way he carefully examined the polarisation in dilute sulphuric acid of all the ordinary metals, and found that every one of them gave secondary currents, although in some instances very slight and transitory; but that those obtained with lead electrodes far exceeded the others both in duration and intensity.

Guided by this observation, he then constructed his famous spiral form of lead accumulator; investigated the best method of "formation" for increasing its capacity, and utilised a number of such cells to carry out a variety of experiments on the heating and other effects of very large currents, which it would have been almost impossible to obtain without their aid. His book should be carefully read by everyone interested in the subject, not only on account of its suggestiveness and the information it contains, but also as an example of the results that may be obtained from the minute and accurate observation of the simplest phenomena, and of the thorough way in which scientific research should be conducted. Although, owing to the limitations of electro-chemical knowledge at that date, his explanations of some of his experiments were necessarily incorrect, later investigations have never, in the smallest particular, impugned the accuracy of his experiments and observations themselves, while many of the points to which he drew attention have only been rediscovered in quite recent years. He noticed the evolution of oxygen from the peroxide pole on breaking the charging circuit; the formation of peroxide at the spongy lead pole when discharged; the presence of unstable compounds (peroxide of hydrogen and persulphuric acid) in the electrolyte; and he further remarked that these latter were produced in greater abundance with lead than with platinum electrodes. Even yet, however, the time was not ripe for the commercial development of the storage cell, and no further advances were made in this direction for some years; but, as soon as the evolution of the dynamo-electric machine reached such a stage as to render the production of large currents at high E.M.F.s a comparatively easy and inexpensive matter, interest in the subject was revived. In 1881 Faure took out his patent for preparing the active material of lead plates from a paste of oxides applied to their surface in order to obviate Planté's long and wearisome process of formation from the electrodes themselves, and the modern history of the accumulator may be said to commence from that date. Since then no alteration in principle has taken place, although the cells have been enormously modified as regards the details of design, construction, and management, so as to render them far more durable and efficient. At first the "pasted" cell was considered to be in every way an advance on the earlier "formed" type, and was for a time employed almost exclusively; but, latterly, improved forms of Planté cells have come into very considerable use, together with a third class, in which the active material is prepared independently by special processes, not only from oxides, but from chloride and other salts of lead, and is then used either alone or with a supporting and conducting frame cast round it; and nowadays all three kinds very fairly divide the honours between them.

The interest and avidity with which the Faure cell was received and taken up caused inventors to turn their attention to the construction of accumulators with electrodes of other metals than lead, for it was perceived that these offered greater possibilities as regards the amount of energy that could be stored for a given weight of metal. Sutton's copper-lead cell, Reynier's zinc-lead cell, and the Thomson-Houston zinc-copper cell are amongst some of the earliest forms of the different combinations tried, and the problem has been again and again attacked, but with such little success that the present day, with the exception of the Waddell-Entz zinc-copper cells on the Third Avenue tramcars, New York, none but lead-lead peroxide cells are in practical use, and the mere term "accumulator" or "storage cell" is tacitly understood to imply this combination, unless specially qualified, the others being regarded by the majority as but little more than electrical curiosities.

The sharp distinctions thus made between lead storage cells and all others, whether primary or secondary, has given rise to a very general notion amongst those who have not specially studied the subject that there must be some fundamental difference in their principles of action by which this may be accounted for, and it is worth while, therefore, endeavouring to show that this impression is an erroneous one, and not at all in accordance with the real facts of the case.

Theoretically, there is no difference between a storage or secondary cell, and a primary cell; both are apparatus for the conversion of chemical into electrical energy. The use of lead peroxide as a depolariser was known to Faraday and others long before Planté prepared it electrically, and if some chemically-prepared peroxide is packed round a plate or rod of lead, and put in dilute sulphuric acid with another plate or rod of lead, surrounded with porous or spongy metal that has not been allowed to oxidise, the combination forms what would ordinarily be termed a primary cell, but one having the same properties as any lead accumulator, whether of the Planté or Faure type. On the other hand, if, instead of putting fresh materials into an exhausted Daniell cell, a current is passed through it in the reverse direction, it forms a Thomson-Houston accumulator; if an exhausted Leland-Chaperon cell is treated in the same way it becomes the germ of the storage cell of Desmazures and many others, and, as has been shown above, the Grove gas cell is a primary or secondary cell, according to the way in which it is set up. In reality, therefore, every secondary cell is a possible primary cell, and every primary cell a possible secondary cell. Even a Grove or Bunsen cell might be recharged electrically if special appliances were provided to collect and retain the fumes or gases that escape during the discharge; and Planté showed that every one of his combinations gave some signs, however slight, of secondary currents. The whole question resolves itself into one of the degree of practical reversibility. Whether it is possible, by passing a current in the opposite direction, to exactly reverse the changes that took place while discharging and restore a cell to the same condition, both chemically and physically, that it occupied at first; or whether it is easier to re-energise it by removing the spent materials and substituting others in their place. Here, then, lies the superiority of a lead-lead peroxide cell to all others. If properly treated it may be regenerated electrically, and so nearly restored to its original chemical and physical state that it can be discharged and charged in this way hundreds or even thousands of times before the total results of the slight changes that do take place depreciate it sufficiently to incapacitate it from further use; while with all other cells the changes that occur with each charging are relatively so large that although every possible means has been tried to reduce them to a minimum, they rapidly deteriorate, and require constant attention and repairs. The reason for the more complete reversibility of a lead cell is entirely due to the chemical behaviour of certain of the compounds into which that metal enters. Lead alone amongst all the metals forms a sulphate that is practically insoluble and unacted upon in water or dilute sulphuric acid, and it also combines with oxygen to form a peroxide having a good electrical conductivity, and equally unaffected by those liquids. When, therefore, a lead-lead peroxide couple is discharged in dilute sulphuric acid, the lead sulphate, which is the ultimate product formed at both poles, does not dissolve up in the solution, but remains on the surfaces of the plates ready for reduction and reoxidation when the current is reversed. Any local action that goes on when the cell is not at work also results in this insoluble sulphate, which tends to form a protecting film on the metal, and thus reduces losses from this cause to a minimum. The compounds formed when any metals other than lead are used as negatives—not necessarily in sulphuric acid, but in any other practically possible electrolyte—are all soluble, and dissolve in the liquid as fast as they are formed, and this simple fact has up to the present barred the way to any substantial progress with these classes of reversible cells.

Without going into the details of the difficulties that have to be met it is sufficient to point out that up to the present,

Digitized by Google

and in spite of the numerous devices that have been tried, it appears almost impossible, firstly, to redeposit the metal either completely or in an efficient condition, and, secondly, to prevent a very serious amount of local action, because fresh surfaces of the metal are constantly exposed as the first portions dissolve up. If, however, these obstacles in the way of further progress can be successfully removed, and there is no fundamental reason why this should not be done, the use of lead for the negatives, at any rate, of storage cells would, in all probability, become a thing of the past; for, as regards its electrical behaviour, there is a good deal to be said against that metal, both theoretically and practically, as is suggested by the fact that it is hardly ever employed in primary cells.

Theoretically, the amount of energy that 1lb. of lead would generate, if wholly converted into lead sulphate, could be produced by about ¼lb. of zinc or iron, or about ½lb. of copper, in spite of the electro-negative character of the latter metal. Practically, the very property of lead, which at present constitutes its superiority to other metals—that is, the insolubility of its sulphate—at the same time seriously limits its efficiency by reducing the energy actually obtainable per pound of metal to a small fraction of the amount theoretically possible. In the first place, the active material requires a grid, or support, of inactive material, which, even in the best forms of pasted cells, will weigh as much as itself, and in Planté cells may be many times its own weight. Secondly, under the best conditions, not more than half the active material is really acted upon, unless the cell is run down below the normal limits, because the sulphate formed on its surface effectually screens the inner portions. The combined effect of these two causes is that not more than 5 per cent. to 15 per cent. of the total weight of electrodes is usefully employed; or, say, 1oz. to 2oz. per lb. of plates.

(*To be continued.*)

THE CONSTRUCTION OF RESISTANCES.*

BY D. K. MORRIS.

Resistances of various kinds are very widely used to facilitate every species of electrical measurement. All cable-testing whether for faults or for insulation, involves the use of resistances of definite value, and resistances capable of absorbing power are of great use in testing continuous-current machines, while similar resistances, designed so as to be non-inductive, are necessary in making tests of transformers or alternators. In fact, almost every electrical test involves the use of resistances of some form or other. The object of the present Paper is to give an outline of the principles which determine the construction of resistances for different purposes, and of the various devices commonly adopted to fulfil the requirements of each.

Resistances may be divided into two groups:—

(1) *Resistances of a fixed and definite value*, which include; first, those not intended to carry appreciable currents, such as standards of resistance and resistance box coils; and, second, resistances designed to carry considerable currents such as are used in potentiometer work. In all these, the changes of resistance, due to unavoidable alterations of temperature, should be a minimum.

(2) *Rheostats and Resistances for the absorption of Power.*—In these, the rise of temperature, due to the current passing through them, must be kept below certain assigned limits, while economy of construction is usually a most important factor in deciding the materials used.

Before proceeding to constructive details, it will be convenient to give an account of the resistance materials most frequently met with.

In the first group, where the variation of resistance with temperature is to be minimised, we have practically only four alloys to deal with—platinum silver alloy, German silver, platinoid and manganin.

In the second group there is a wider choice of materials, for the accurate value of the resistance is not so important;

Data of Resistance Materials.

—	Composition.	Specific resistance at 15° C. (= ohms per cm. × 10^9)	Change of Resistance % for a rise of 1° C. at 15°.
For Wires.			
Manganin	Cu, 84%; Mn, 12%; Ni, 4%.	46,800	less than ·001%
Platinum Silver ...	Pt, 33%; Ag, 67%	31,700	·024%
German Silver	Cu, 50%; Ni, 25%; Zn, 25%	30,100	·027%
Platinoid	same as above with 1 to 2% of Tungsten	41,900	·031%
Manganese Steel ...	a Steel containing 12% of Manganese	68,400	·125%
Iron	......	10,600	·480%
Miscellaneous.			
Carbon	......	about 4,000,000	–·026%
Mercury	......	95,400	+·071%
Dil. Sulphuric Acid	1 of acid to 12 of Water.	3,300,000,000	–1·5%
Sulphate of Zinc ...	Saturated solution at 15°C.	50,000,000,000	–2·3%

besides some of the previous, we have manganese steel and iron wires, carbon in various forms, and some conducting solutions.

In the table which I have prepared here you will see the composition, the specific resistance at ordinary temperature, and the temperature coefficient which I have calculated so as to answer to the definition at the head of the last column; the figures in this table are largely taken from the recent Paper by Profs. Dewar and Fleming on the "Electrical Resistance of Metals and Alloys at Low Temperatures." Of course, the materials commercially obtainable under these various names often differ much from the figures here quoted, not only in specific resistance, but even more in temperature coefficient.

The relative values of the figures in the last two columns—that is, of the specific resistance, and its percentage variation per degree centigrade, are, except for the non-metallic materials, illustrated graphically on this diagram (Fig. 1). Along the base line we have degrees of temperature centigrade from the freezing point up to 200 degrees,—just short of the point at which paper is charred; while the ordinates represent the specific resistance; that is, the resistance of a centimetre cube in C.G.S. units (electromagnetic).

This is the way it is usually given. In order to give one a practical idea of its meaning, it is, I think, convenient to bear in mind, that, very roughly, the specific resistance divided by 100 is equal to the resistance in ohms of a mile of No. 17 B.W.G. wire; or, again, it is equal to the resistance of 100 yards of No. 28. For instance, given that the specific resistance of iron is 10,600, we can say at once that 100 yards of No. 28, or a mile of No. 17, iron wire have each of them a resistance of 106 ohms approximately.

The line for copper has been added on the diagram to show how very small its resistance is compared with our other materials. The temperature coefficient at any point on a curve is represented to some scale by the slope of the curve divided by the ordinate at that point. For instance, copper, which, as you know, has nearly as large a temperature coefficient as iron, has a much smaller slope, but a correspondingly smaller ordinate.

We see from that diagram that manganese steel, which contains 12 per cent. of manganese, has by a long way the highest specific resistance of any substance available in the form of wires, if we except one or two alloys of which we know very little. As an instance of such an alloy there is a resistance material which has been brought out comparatively recently by Messrs. Krupp and Co., of Essen, which they call "Kruppin." Its specific resistance is said to be 83,000, which is greater than that of manganese steel, while its temperature coefficient is about the same.

Manganin, which is, I think, used much more on the Continent than here, is remarkable as having very little or no variation of resistance with temperature. It is an alloy con-

* A Paper read at a Student's Meeting of the Institution of Electrical Engineers, March 16, 1894.

Digitized by Google

taining about 84 per cent. of copper, 12 per cent. of manganese, and 4 per cent. of nickel. The form of its resistance-temperature curve is shown in Fig. 2, there being a temperature of maximum resistance. The specimen tested by Dewar and Fleming in the experiments for the Paper previously referred to had its point of maximum resistance almost exactly at ordinary temperatures—about 15°C., but slight variations in its composition seem to shift this point considerably. However, even at 200°C., the decrease of resistance per degree rise of temperature was only $\frac{1}{100}$th per cent., which is still less than half that for any other substance.

You will see from the diagram that iron wire, which is rather handy for absorbing power, fully doubles its resistance by the time it gets fairly hot; while if carbon is used, in the shape of incandescent lamps, its resistance, when taking its full current, is practically one-half of what it is when measured cold.

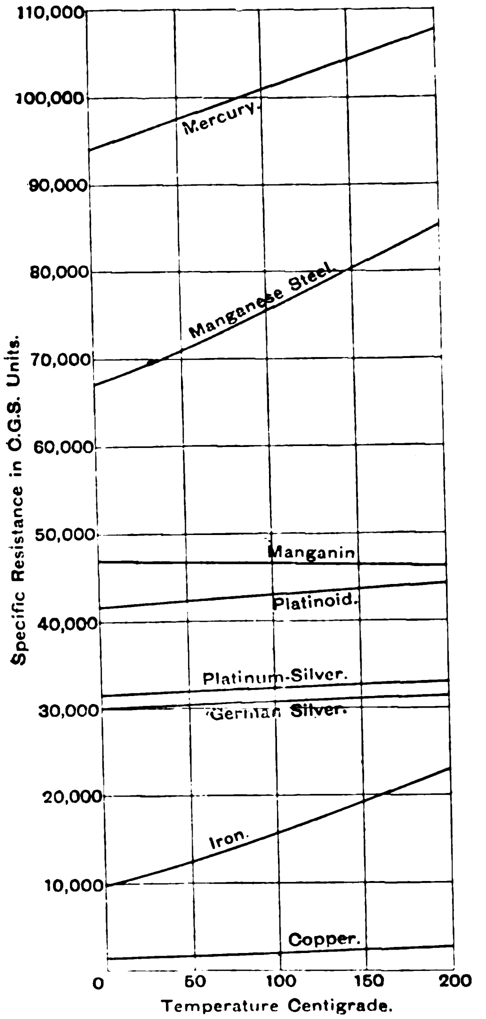

FIG. 1.—Resistance-Temperature Curves of Metals used for Resistances, the curve for Manganese Steel being drawn to Half Scale of Ordinates.

The temperature variation of resistance of the liquids with which we are concerned is much greater, being, in the case of a saturated solution of sulphate of zinc, a diminution of resistance of as much as 2·3 per cent. for a rise of 1°C.

Having now gained some idea of the properties of resistance materials, we can go on to the resistances themselves.

(1) *Resistances of a Fixed and Definite Value.*—First, not intended to carry appreciable currents.

Standards of Resistance.—The first standard of resistance which was at all practically used was that introduced by Werner Siemens. It consisted of a column of mercury 1mm. in cross-sectional area, and a metre in length—mercury being chosen because of the ease with which it can be obtained in a state of purity. This, of course, was only an arbitrary standard.

The elaborate researches which have been conducted on the evaluation of the ohm and other "absolute" units have had as their object the expression of these units in terms of the mechanical units which were previously in use, so that they might not have to depend ultimately on the electrical properties of any given metal or alloy. It has been decided that the best way of constructing a reproducible standard is that used by Siemens in the construction of his unit, mentioned above. Thus the standard ohm is defined as the resistance at 0°C. of a column of pure mercury 1 sq. mm. in section, and of a length which is determined by absolute measures. There have been many attempts to obtain this length, and the nearest approximation to the true ohm which we have at present is obtained when this length is 106·3cm. Hence the international ohm, as it is called, which was agreed on last summer at the Chicago Congress, is defined as the resistance of a column of mercury 1 sq. mm. in section, whose length is 106·3cm.

Mercury standards of resistance, though accurately reproducible from the previous definition, are obviously very inconvenient to preserve or use; for this reason secondary standards, in which the resistance material is in the form of wire, are used.

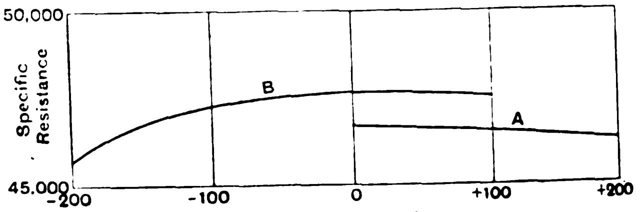

FIG. 2.—A, Manganin after Annealing. B, Manganin before Annealing at 100 C.

Such standards should not alter their value with lapse of time; they should be capable of assuming a certain specified temperature with rapidity, and their temperature coefficients of resistance change should be small, so as to minimise the error due to an inaccurate estimate of their temperatures.

German silver, which was used in the earlier resistance standards, is liable to become rotten in course of time, owing to the crystallisation of the zinc which it contains.

Manganin, which commends itself at once for such a purpose owing to its negligible temperature coefficient, is unfortunately liable to change in consequence of the oxidation of the manganese. And, practically, so far as we know, an alloy of one of platinum to two of silver is the only available substance for the construction of a really permanent standard of resistance.

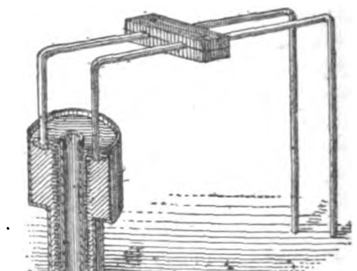

FIG. 3.

The form of standard which was introduced by the British Association is made as follows: The actual coil, the wire of which is doubled back on itself to avoid self-induction effects, is wound on a brass tube having ebonite cheeks; to the upper cheek, two long bent copper rods, kept separate by an ebonite distance piece, are attached, Fig. 3. The coil is then placed in an annular brass vessel, which is then filled up with paraffin wax.

It is, however, very difficult to get a large mass of substance, such as paraffin, which insulates heat as well as electricity, to assume a given surrounding temperature, as that of ice and water. It is also much more easy to determine the temperature of a given layer than it is to determine the mean temperature in a deep vessel. Hence the modification of the design by Dr. Fleming:—

The case or shell which contains the coil is in the form of a ring, Figs. 4 and 5, this ring consists of a pair of shallow circular

Digitized by Google

troughs of brass, provided with flanges, which can be screwed together so as to form a square-sectioned annular space.

From this ring proceed upwards two brass tubes through which, though carefully insulated from them, pass two stout copper leads, as in the B.A. standard. The actual resistance coil is formed of a length of three-fold silk-covered platinum-silver wire, which is first baked above 100° C to dry it completely, and then immersed in melted paraffin wax. The wire is then cut the proper length, folded once on itself, and wound

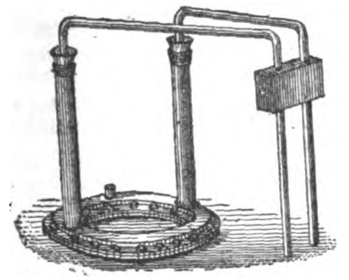

Fig. 4.

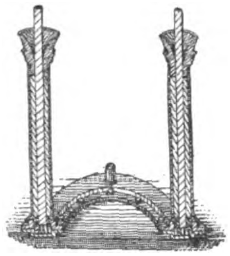

Fig. 5.

on a wooden mandrel of such a shape that the coil, when wound, will drop loosely into the hollow of the brass ring. After further insulation, it is packed into the upper circular groove, the resistance is accurately adjusted, and the bottom half of the ring is screwed on, the joint being made good by a thin indiarubber washer. Such a standard coil not only is capable of assuming the surrounding temperature conditions rapidly, but any heat produced by the current used in comparing its resistance, is quickly got rid of.

(To be continued.)

THE CANDLE-POWER OF GLOW LAMPS.*

In order to possess a full knowledge of the behaviour of the lamp as an energy-translating device, it is necessary to know four things about it. First, we must know the current, in amperes, which is taken by the lamp when a certain electric pressure is produced between the ends of the carbon filament. Generally speaking, lamps are denominated by the pressure at which they must be worked to give satisfactory results as to duration. This pressure measured in volts is called the *marked volts* or *maker's volts*, and lamps may be distinguished as 100-volt lamps, 50-volt lamps, 10-volt lamps, &c. The current taken by a lamp can be measured by many kinds of instruments, which are called *ampere-meters* or ammeters. The pressure between the terminals of the lamp can be measured by suitable *voltmeters*. Approximately speaking, a lamp intended to work at 100 volts and to give 16 candles light has a carbon filament about 5in. long and about $\frac{1}{100}$th of an inch in diameter, and when worked at a pressure of 100 volts it takes from $\frac{3}{5}$ths to $\frac{2}{3}$rds of an ampere. If we divide the number representing the electrical power in watts taken by the lamp by the number representing the candle-power of the lamps, the quotient gives us the number representing the *watts per candle-power*. In most modern lamps this last number varies from $2\frac{1}{2}$ to $3\frac{1}{2}$, when the lamp is being used at the marked volts. There are therefore four quantities in connection with every lamp which it is important to know. First, the *marked volts* or voltage of the lamps; second, the *ampere current* taken by the lamp at the marked volts; third, the *candle-power* of the lamp; and, fourth, the *watts per candle-power*.

It is important that, in making thus a determination of the constants of a lamp—viz., the current passing through the lamp, the pressure difference at the terminals of the lamp, and the candle-power of the lamp by comparison with a suitable standard of light—these quantities should all be measured at the same instant. By varying the current through the lamp, as we can do by using pressures of different values, we can obtain a series of observations by which the candle-power, current, and volts on the terminals of the lamp are all measured simultaneously for different values of the pressure on the lamp terminals, and these values can be set out in a series of curves which are called the characteristic curves of the lamp. In Fig. 1 is shown a curve illustrating the manner in which the light of a 16-c.p. lamp varies as the current changes. It

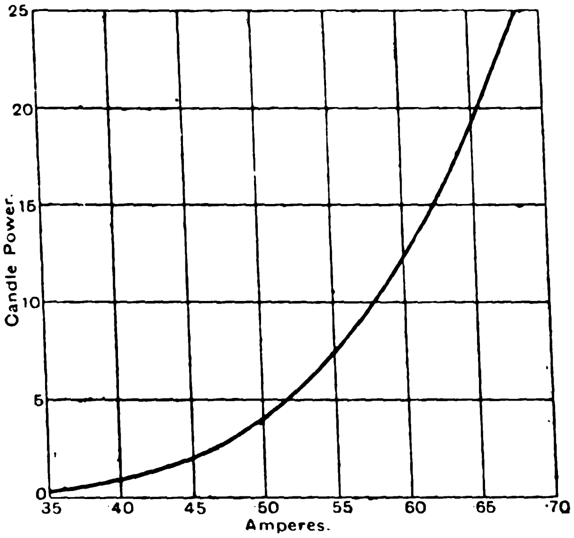

Fig. 1.—Curve showing Variation of Candle-power with Current in a Glow Lamp.

will be seen that a very small increase in the current is accompanied by a large increase in the light of the lamp, and it can be shown that the candle-power varies very nearly as the sixth power of the current. That is to say, if a lamp gives 1 candle light when a current of one ampere is passing through it, then it would give $2 \times 2 \times 2 \times 2 \times 2 \times 2 = 64$ candle-power if two amperes were passed through it. For a reason to be explained later, however, no lamp would bear such a relative increase in current. But the above-mentioned law

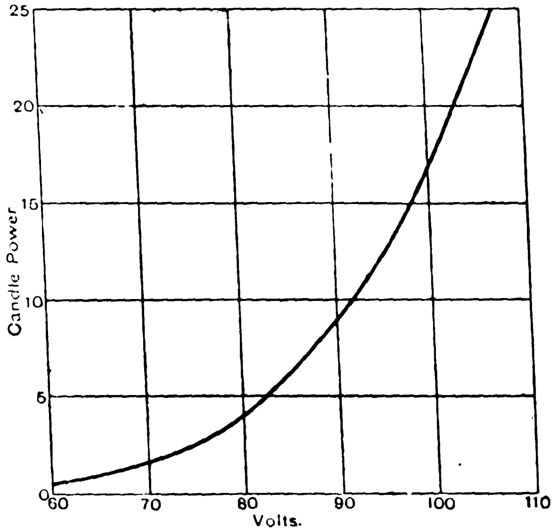

Fig. 2.—Curve showing Variation of Candle-power with Voltage in a Glow Lamp.

holds good proportionately for all glow lamps; viz., that the candle-power varies approximately as the fifth or sixth power of the current. In Fig. 2 is shown another curve, illustrating the manner in which the candle-power varies with the volts, and in Figs. 3 and 4 curves showing the manner in which the candle-power varies with the watts and with the watts per candle-power. From the curve in Fig. 3 it will be seen that the candle-power of the lamp varies very nearly as the cube of the total power in watts supplied to it. In other words, if we supply the lamp with twice the electrical power, the

* From a forthcoming work on "Electric Lamps and Electric Lighting," by Dr. J. A. Fleming, to be published by *The Electrician* Printing and Publishing Company. All rights reserved.

Digitized by Google

candle-power is increased eight times. If we supply it with three times the electrical power, it is increased twenty-seven times. These curves will show, amongst other things, the great importance of preserving the pressure at the terminals of a lamp quite constant when that lamp is used as an illuminating agent. Any variation of the pressure, however small, produces a very serious variation in the candle-power of the lamp. It is convenient to bear in mind the following figures for the 16-c.p. lamp as generally made. Such a lamp

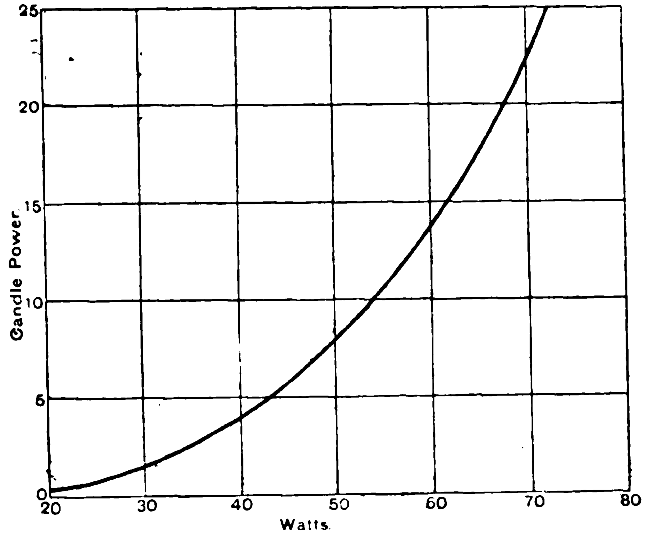

Fig. 3.—Curve showing Variation of Candle-power with Wattage in a Glow Lamp.

takes, when worked at a pressure of 100 volts, 0·6 or $\frac{3}{5}$ of an ampere, absorbs 60 watts of power, and therefore in $16\frac{2}{3}$ hours consumes an amount of energy which is $16\frac{2}{3}$ times $60 = 1{,}000$ watt-hours. This amount of energy is called one Board of Trade Unit, and is generally sold by the Electric Supply Companies in England at prices varying from 3d. to 8d.

As soon as we begin to use incandescent lamps in practice, even although the pressure at the terminals may be kept exceedingly constant, we find that lamps are like human

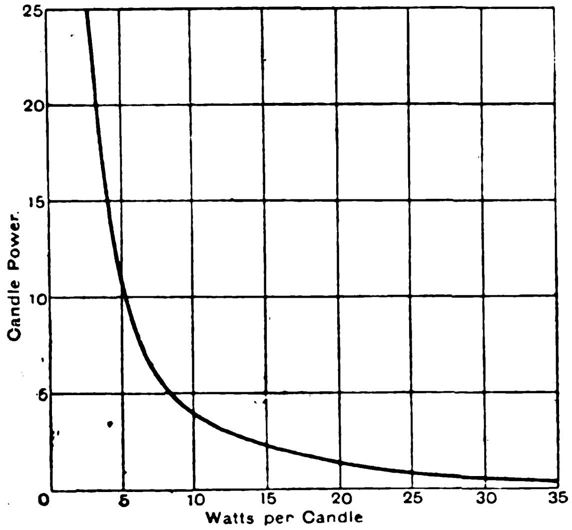

Fig. 4.—Curve showing the Variation of Candle-power with Watts per Candle-power in a Glow Lamp.

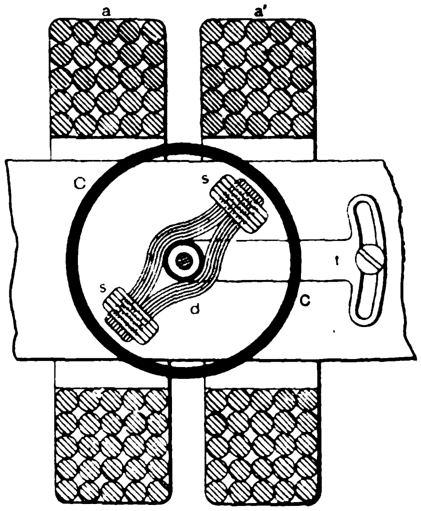
beings—they have a certain life or duration, and, moreover, most of them undergo a process of deterioration in light-giving power. After a certain time the filament of the lamp is destroyed, and the lamp ceases to work. The duration of any lamp when worked under certain conditions as to pressure and supply is called its *life*, and from a large number of observations of similarly constructed lamps when worked in a particular manner we can deduce the *average life* of a lamp. We cannot predict from observations of one or two lamps what the average duration will be, any more than we can tell from observations on one or two human lives what is the average duration of human life in any place. The life of any particular individual lamp may be only a few hours, or it may be many thousands of hours. This average duration is only one factor in determining the real value of the lamp as a translating device. Apart from accidental circumstances, the factors that determine the life of the lamp are the temperature at which the carbon filament is kept, and the nature of the surrounding gas. Assuming, however, that an incandescent lamp is supplied with electric current at a constant electric pressure: it is always found that two marked changes occur in the lamp in the process of time; first, the lamp begins to blacken by a deposit of carbon which is made upon the interior of the bulb; and, second, the carbon filament undergoes a change by which its electrical resistance becomes increased and its surface altered, so that, whatever its initial condition, its surface finally assumes a much darker and more sooty appearance than when first manufactured.

THE DUNCAN ALTERNATE-CURRENT METER.

One of the problems which has confronted electrical engineers has been the invention of a commercial alternating current recording meter which will record "all" loads correctly. In the early days of electric lighting it was customary to charge so much per lamp per week, month, or year, because there were no practical recording meters. This was, of course, most unsatisfactory both to supply companies and to consumers.



Before long various types of recording meters appeared, which recorded, it is true, but gave no satisfaction; for the greater part of them made electric light very cheap for the small consumers and very expensive for the large, on account of the slow speed on a small number of lights.

A meter which, it is claimed, solves the problem, and which is dependent on the principle of the repulsion of a closed secondary from its primary, and is a practical development of Prof. Elihu Thomson's experiments, has now been brought out by Mr. Thomas Duncan, of Fort Wayne, Indiana. The essential parts of the meter are the primary or field coils *a*, *a'*, which are connected in series with the lamp circuit, the secondary or armature C consisting of an aluminium cylinder, a magnetic path-diverter, *d*, made of laminated iron, and carrying a closed secondary, *s*, which consists of several copper punchings; the aluminium fans, the registering train, and the spindle which carries said armature and fans. The armature has no electrical connection with the circuit. It is claimed that the speed on one light is a few per cent. slow, on some as low as 2 per cent., but that on all other loads the meter is correct.

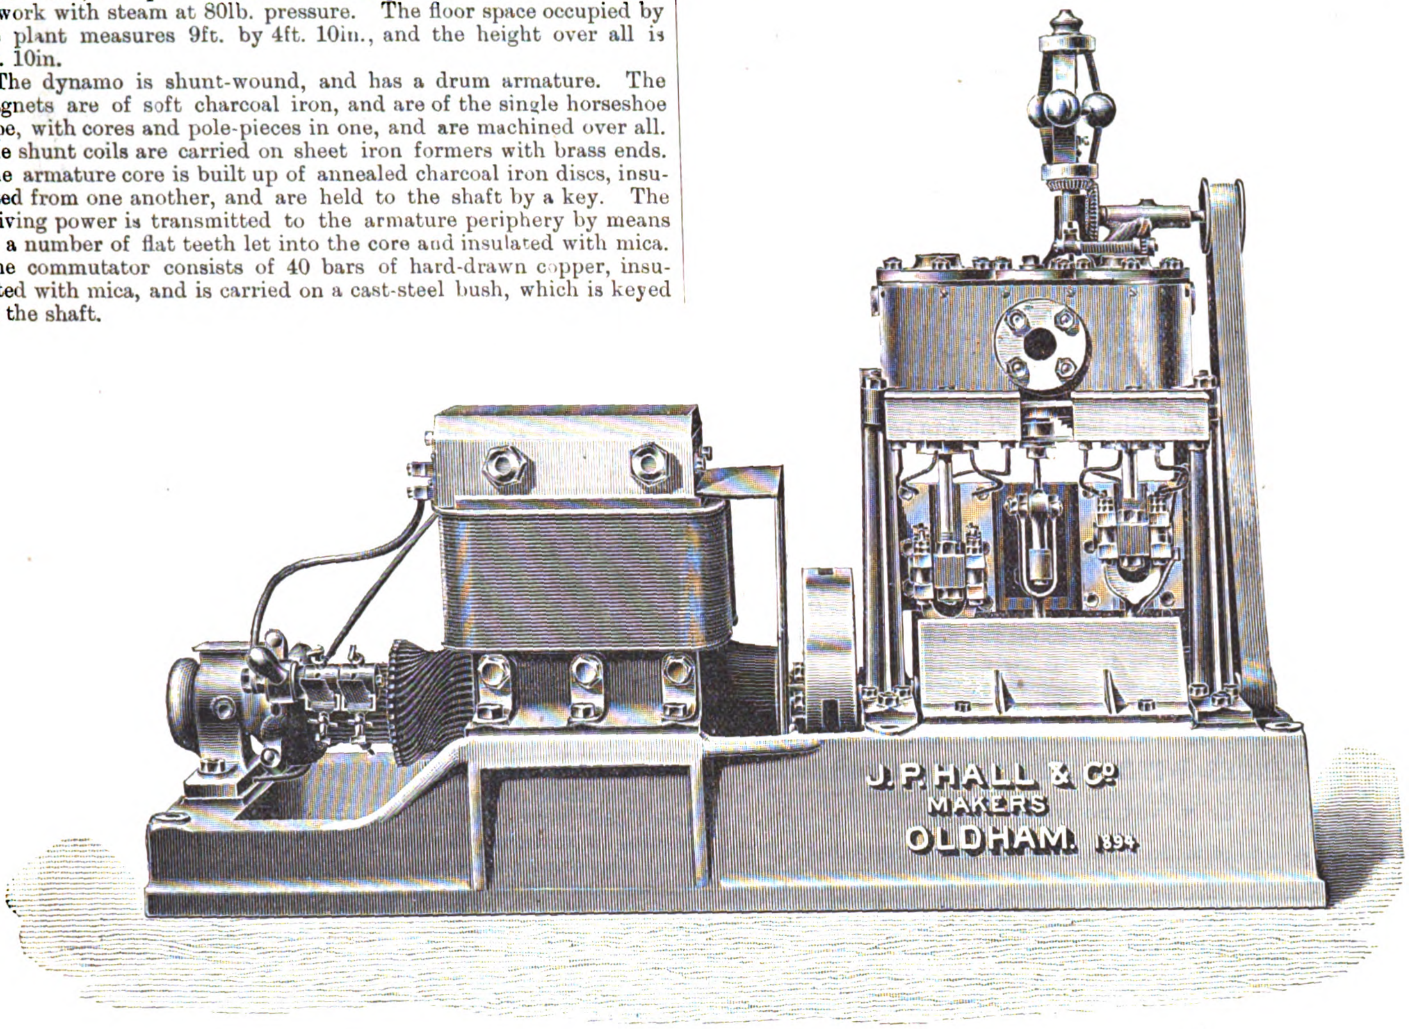
COMBINED ENGINE AND DYNAMO.

The accompanying illustration shows a combined steam engine and dynamo, manufactured by Messrs. J. P. Hall and Co., of Oldham. The plant is designed to give an output of 40 amperes at 100 volts, at a speed of 500 revolutions per minute, and is intended to work with steam at 80lb. pressure. The floor space occupied by the plant measures 9ft. by 4ft. 10in., and the height over all is 3ft. 10in.

The dynamo is shunt-wound, and has a drum armature. The magnets are of soft charcoal iron, and are of the single horseshoe type, with cores and pole-pieces in one, and are machined over all. The shunt coils are carried on sheet iron formers with brass ends. The armature core is built up of annealed charcoal iron discs, insulated from one another, and are held to the shaft by a key. The driving power is transmitted to the armature periphery by means of a number of flat teeth let into the core and insulated with mica. The commutator consists of 40 bars of hard-drawn copper, insulated with mica, and is carried on a cast-steel bush, which is keyed to the shaft.

3in. The bearing surfaces are of phosphor-bronze, and are made very large; that at the dynamo end is designed as a thrust bearing, to take up the end thrust of the armature. The engine is controlled



The steam engine is a twin-cylinder high-pressure engine, the diameter of each cylinder being 4½in., and the stroke of the pistons

by a Pickering high-speed governor, driven by a strap. The lubrication is effected from one main oil box.

HIGH-FREQUENCY CURRENTS.

Mr. F. Himstedt publishes in *Wiedemann's Annalen*, Vol. LII., p. 473, some methods of repeating Tesla's experiments which are of some interest. As he did not possess Tesla's elaborate apparatus, he first resorted to electric oscillations produced by the Lecher arrangement, and later on, plain Leyden jars. He connected the poles of a strong Ruhmkorff's coil, 50cm. long, 20cm. in diameter, and worked by five or six accumulator cells to the inner coatings of two Leyden jars of moderate size, insulated from one another on blocks of paraffin wax, and also to a spark micrometer. The outer coatings of the jars were connected by a copper wire 4mm. thick, and 150cm. long, bent into U-shape. A 16-volt glow lamp, put in parallel with this wire, soon became white hot when the micrometer was suitably adjusted. Using jars of 16cm. diameter and 42cm. height as many as three lamps could be made to glow simultaneously one over another; namely, a 65-volt lamp below, a 16-volt lamp in the middle, and a 2-volt lamp at the top. If the point of the glass globe be filed off, the lamp ceases almost entirely to glow. Tesla ascribes this to the different manner of the bombardment of the gas molecules in the globe, the author thinks it due to convection. If the incandescent body be a platinum wire of from 0·05 to 0·1mm. diameter, it oscillates violently during incandescence, and showed as a zigzag line; but it does not swing in a plane like a string, but in all possible planes, appearing like a beam of light.

It is necessary for the success of the experiment to have an interruptor working regularly, and a suitable spark micrometer. The former should be a Foucault interruptor with tough zinc amalgam under oil replacing the mercury, and the micrometer balls should be of zinc. A Tesla transformer was made as follows: a wire 4mm. in diameter was wound on a glass tube 4cm. thick, in ten turns 1cm. apart, over this an ebonite tube was pushed, on which was wound 200 turns of wire 1mm. thick, about 1mm. apart. This was placed in a suitable earthenware bath containing machine oil, and its secondary connected to two metallic spheres supported on ebonite pillars. The primary was connected to the Leyden jars in the place of the U-wire. When the interruptor is working, brush discharges take place from the knobs, sparks take place to a conductor held near. If two parallel wires go out from the knobs a broad band of light shines out brightly up to three or four metres away. If one pole be connected to earth, and a fine wire 15-20cm. long be hung on the other, the wire begins to move and describes the surface of a cone, easily seen in the dark, by the brush discharge all along the wire.

If anyone touch one pole, rays of light go out from any part of his body to a conductor held near. If he stand on a metal plate, he feels a pricking sensation in the feet, and brush discharges are seen coming out of the soles of his shoes. If several persons form a chain, and the first touch one pole of the transformer, while the

Digitized by Google

last holds a Geissler tube, with or without electrodes, in his hand the tube glows brightly, and none of the persons feel anything whatever.

If one pole of the transformer be earthed, while the other is connected to a large metallic sphere 60cm. in diameter, Geissler tubes three or four metres away glow brightly. A glow lamp connected o he unearthed terminal glows only with the phosphorescent light o ia Geissler tube, but it glows brightly if covered with a tin-plate shade. The filament oscillates so violently that it soon breaks. If a conductor be brought near the point of the lamp, the globe is broken and a continuous stream of sparks passes through the opening, and the carbon filament continues to glow till it is all burnt away.

In the second portion of his Paper the author informs us of some curious facts. The transformer differs from an ordinary induction coil in a curious way. A vacuum tube connected to it gives cathode light at both ends, and anode light in the middle. Reversing the current, or connecting to the other pole makes no difference. An electroscope is always positively charged when put near a point connected with either pole, and only positive Lichtenberg figures can be produced with it.

Experiments with different gases showed that the predominance of positive electricity in the transformer had its cause in the surrounding medium. Air and oxygen give positive discharges; while hydrogen, coal-gas, nitrogen, carbon dioxide, and ammonia give negative. If one pole be made with two points of discharge, one in hydrogen, and one in air, positive and negative electricity come out of the same pole in accordance with the nature of the medium; and a gradual alteration from positive to negative can be obtained by diluting oxygen with more and more nitrogen; the maximum positive effect being produced when the mixture is in the proportion of the constituents of the atmosphere.

On the other hand, when an induction coil is used instead of the transformer, the reversal of the current always reverses the charge of an electroscope held near, whatever the nature of the surrounding medium.

AN INSTRUMENT FOR DETERMINATION OF PHASE DIFFERENCES WITH ALTERNATING CURRENTS.*

BY M. VON DOLIVO-DOBROWOLSKY.

It may be said of modern alternate current working that it is the utilisation of differences of phase, for most of the newer applications of alternate currents have as their basis the phase difference of two currents, or of current and pressure; while the resolution of the alternating current into its idle and working components is now all important.

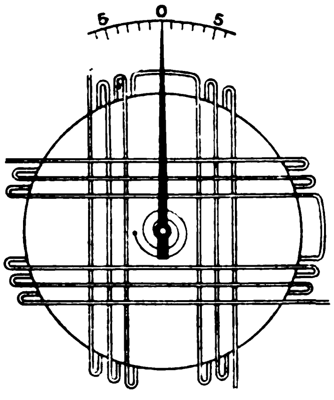


Fig. 1.

The resultant current may be measured directly by an ammeter or dynamometer, and the working current may be found by wattmeter and voltmeter, or at given volts from a wattmeter reading directly, and from the ratio of the working to the resultant current, the idle current, and the phase-displacement may be graphically determined; but there are cases in which a direct measurement of the idle current is most valuable, not to say indispensable, and the phasemeter here described is essentially an ampere meter measuring the idle current.

The apparatus resembles in its arrangement a three-phase motor; it is shown in its simplest form in Fig. 1. Two coils at right angles to one another surround an iron disc, arranged to rotate on points. If the two alternating currents which traverse the coils differ in phase, then, as is well known, there is a torque on the iron disc. This torque has the value $D = a\, i_1 i_2 \sin O$, where $i_1 i_2$ are the two currents and O the angle of lag. The rotation of the iron disc is opposed by a spring, the amount of deflection from zero being then a measure of the torque, and therefore of the difference of phase.

If one of the coils be wound for voltmeter current, Fig. 2, with a large induction less resistance in series with it, the current in this portion will be approximately in step with the volts; and if the other coil be used as a current coil, carrying the main current, then the deflection measures any difference there may be between current and volts, $D = a\, i\, e \sin O$, while the direction of deflection shows whether the current has a lead or a lag.

If the instrument is always to be used at the same voltage, or if allowances can be made by adjustment of the voltmeter-coil resistance to suit any small variation, then the formulæ above becomes $D = b\, i \sin O$; but $i \sin O$ is the idle current, and thus in this case the deflection is directly proportional to the idle current. The Allgemeine Elektricitäts Gesellschaft will shortly place the instrument on the market. (Fig. 3.)

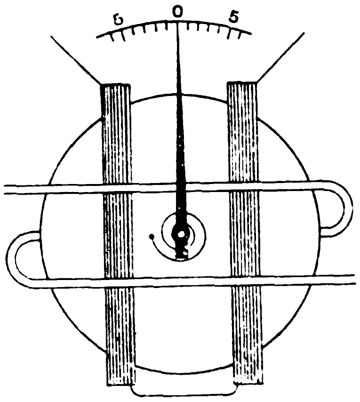

Fig. 2.

The scale is so graduated that at the given volts and frequency the phasemeter reads directly in amperes the value of the idle current; and small differences of pressure and frequency affect the reading by an amount directly proportional to the alteration. The most important application of the new instrument is to central stations running their alternators in parallel, and also to transmissions using so-called synchronous motors. It ought to-day, since the epoch-making work of Mordey and Swinburne, to be a matter of common knowledge that it is useless to try and govern alternators running in parallel by alteration of the excitement, since this only produces an armature reaction tending to neutralise its effect; the current so produced is an idle current, and is generally known as the synchronising current. It may lead or lag behind the E.M.F., strengthening or weakening the field. It is obviously best to reduce this current as much as possible, owing to the power needlessly wasted by it in the armatures; but one must be careful that the machines do not get out of step, and for the purpose of the regulation the present instrument is very valuable, as the sign and magnitude of the synchronising current can be determined, and the excitement of the machines adjusted to the best value. If there is no phase displacement due to the external circuits, the phasemeter should indicate 0; and if a displacement, due to motors for instance, exists, each phasemeter should indicate in the same direction and about the same amount, this being the most advantageous arrangement. With the phasemeter, therefore, it is possible to utilise the alternate-current station to its full capacity; to bring the machine to zero of current when switching off, thus avoiding flickering of the light, and to judge of the output of the machines into the mains. The annexed figure (Fig. 4) shows the

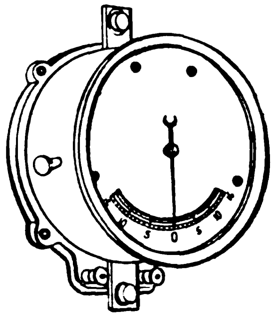

Fig. 3.

* Abstract from the *Elektrotechnische Zeitschrift*, June 21, 1894.

Digitized by Google

arrangement and connections of an alternate-current station fitted with phasemeters ; M M are the machines, fitted the omnibus bars $L_1 L_2$. H H are the switches, with the synchronisers *i i* ; and in the circuit of each machine is an amperemeter and a phasemeter. The ammeters can be advantageously replaced by wattmeters, the phasemeters having their current coil in circuit with the dynamos, and their pressure coil on the omnibus bars ; this latter arrangement being capable of simplification as shown, by using the common series resistance S, which may have adjustable self-induction to bring the phasemeter readings to O when motors are on the mains. The machines have in addition each a voltmeter and a field regulator ; while a main regulator, R, enables the voltage on the mains to be adjusted as required. If during the running the phasemeters have all the same deflection while one machine is doing too little work, the only remedy is to regulate the steam (or water) supply, and thus alter the power given to it.

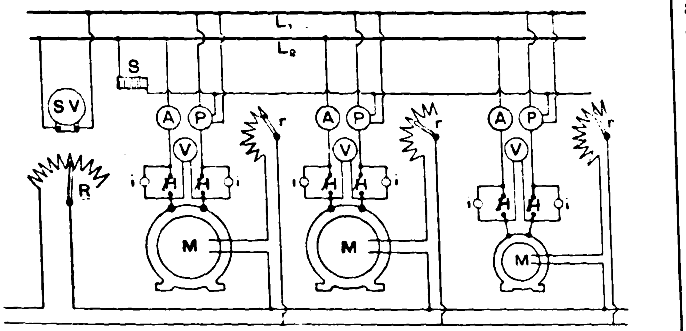

FIG. 4.

When a dynamo is to be switched out, steam should be gradually cut off, keeping the phasemeter on O by means of the field regulator, until the ammeter shows no current, when the main switch H is opened. In a similar manner the most favourable excitement for a synchronous motor at any given load may be found, and thus the $C^2 R$ losses reduced to a minimum ; and the phasemeter in general may be said to add considerably to the simplification and safety of the station.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *September* 1, 1894.

Electric Locomotives.—The General Electric Company has just completed a forty-ton electric locomotive, designed for speeds not exceeding thirty miles per hour. The draw-bar pull is 14,000lb., the wheel-base 6ft., and the diameter of drivers 40in. The two trucks are similar to those of ordinary passenger cars, and the motors, one on each axle, are of the single-reduction spur-geared type, mounted as in ordinary street-car practice. The Baltimore and Ohio Railroad Company will soon have several large electric locomotives in use for transferring its trains through Baltimore, its lines there passing through a series of tunnels under the city. A locomotive, designed by Sprague, Duncan and Hutchinson for the Chicago terminal of the Northern Pacific Railroad, will be ready for use in about a month. This is the largest electric locomotive yet designed in this country, weighing 65 tons, and developing 1,000 H.P. The frame of the locomotive is similar to that of the ordinary standard steam type, but with a four-pole motor built directly to each of the four axles. The drivers are 52in. in diameter, and the speed is to be 35 miles per hour.

Canadian Electrical Transmission Plant.—The Stanley-Kelley Company will instal a large two-phased plant at Montmorency Falls, near Quebec, the generators to be three in number, of 675 H.P. each. The current will be generated at 5,500 volts, and conveyed to Quebec, 8 miles distant, by four wires for each machine, with a line drop of 6 per cent. At a sub-station in the city step-down transformers will reduce to 2,000 volts, which will be the voltage of the distributing system. The transformers will be cooled by an air draught. The current will be used for both lighting and power service.

The Tariff Bill, recently passed, though drastic in some of its provisions, will have little or no effect in increasing American electrical importations. The reduction of the duty on incandescent lamps from 60 to 35 per cent. might place this branch of trade within reach of foreign competition at present prices, but it is probable that such competition would be met by a cut in domestic prices. The new rates may, however, lead to importations of armature plates and field forgings, as well as of porcelains for electrical insulation and electrolier glass shades.

NEW YORK, *September* 7, 1894.

Accumulator Litigation.—A decision has been handed down by a United States Court denying the motion of the holders of the Brush accumulator patents for a preliminary injunction against the manufacturers of the chloride accumulator. The Court holds that the testimony submitted by the complainant to maintain the claim of infringement is based upon too broad a construction of the claims of the Brush patent, and upon a yet broader construction of the decisions of the Courts which have sustained these patents. While the real merits of a case are but slightly examined into on a motion for a preliminary injunction, yet the language of the Court in this case is regarded by those interested as decidedly favourable to the chloride accumulator.

The Commercial Cable.—On September 1st, the laying of the last four miles of the in-shore end of the Commercial Cable Company's cable was completed, and on Sunday morning the harbour section was laid and connection made with the Company's shore lines at Pier A, North River. This is the first direct cable connection with New York City.

The New York Electrical Society.—This Society during the past year, instead of listening to the reading of Papers at all of the regular monthly meetings, has adopted the policy of making occasional visits to inspect features of electrical interest. This new departure is much appreciated, and has resulted in a large increase of membership. The Society as a body, for instance, attended a performance of "Sinbad," in which electricity plays a large part, and at the opening of the new Postal Telegraph building made an official visit of inspection to its large electrical plant and examined its equipment. Several days ago, upon the invitation of the proprietors, the members visited the Wild West show during a night performance, and after it were shown the very complete electrical installation of this show, which gives night performances. This plant consists of four 80-kilowatt dynamos, which supply current to 800 incandescent lamps, 77 2,000-c.p. arc lights, 46 2,000-c.p. arcs with corrugated glass diffusion reflectors, and several search lights. The distribution of light is such, notwithstanding the immense area of the grounds, that the night performances are as satisfactory to the audiences as day ones.

CORRESPONDENCE.

THE GOVERNMENT AND THE TELEPHONES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : From time to time you have criticised the action of the National Telephone Company and the Government, with respect to an agreement between them on the question of telephonic communication throughout the United Kingdom.

The following letter may be interesting to yourself and readers at the present juncture :—

[COPY]. General Post Office, London. September 7, 1894.

SIR,—I am directed by the Postmaster-General to acknowledge the receipt of your letter of 3rd inst., on the subject of the proposed establishment of a local telephone exchange in —— and to acquaint you, in reply, that it is not competent for any person or company without the license of the Postmaster-General, to transact telephonic exchange business within the United Kingdom. The question of the grant of a licence for such business is, however, solely one for the consideration of the Postmaster-General ; and under the proposed new agreement between the Postmaster-General and the National Telephone Company, to which you refer, the rights of the Postmaster-General in this respect are expressly reserved.

I am, however, to say that, as the whole question of telephonic communication is still open to discussion when Parliament meets next year, the Postmaster-General does not see his way to entertain applications for fresh licences.

Mr. Arnold Morley thinks it right, at the same time, that you should be informed that, as will be seen on reference to paragraphs 51, 52, and 53 on page 438 of the "Post Office Guide" for the present quarter, the Post-

Digitized by Google

master-General's exclusive right of transmitting telegrams extends, not only to the transaction of telephonic exchange business, but also, with a few specified exceptions, to the establishment of any telephonic communication whatever within the United Kingdom.—Yours, &c.,

T. Vaughan Hughes, Esq. (Signed) SAM ARDRON.

It seems strange that local telephonic business in the country is to be blocked for some months because certain agreements between the Postmaster-General and a limited liability company are not yet ratified. The National Telephone Company have surely been masters of an unenviable situation while their patents were in force quite long enough for those who have had experience of the telephonic service of other countries.—Yours, &c.,

T. VAUGHAN HUGHES.

A PROPOSED INTEGRATOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In connection with your report of Prof. Henrici's Paper on planimeters, read before the British Association, the following description of a possible integrator, to be used in the same way as Amsler's, may be interesting. (Fig. 1).

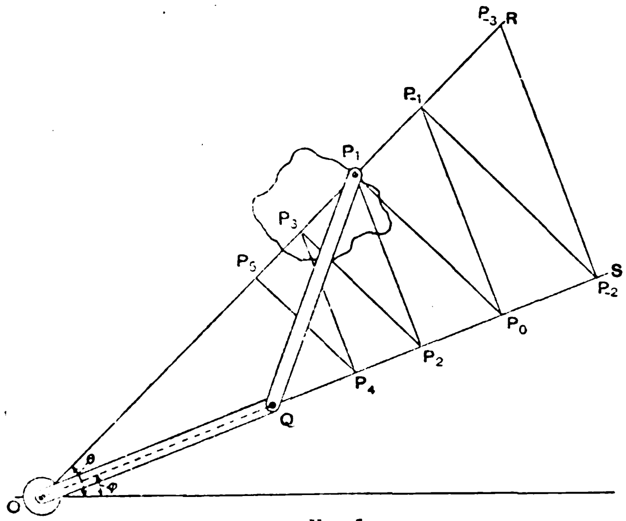

FIG. 1.

O Q . Q P_1 . are equal links of fixed length, pivotted together at Q, and turning about a fixed point, O.

P_1 is the tracing point.

Points ..... P_4, P_3, P_2, P_0, P_{-1}, P_{-2}, P_{-3} .... are found by drawing perpendiculars alternately on O P_1 R, O Q S.

If wheels placed at those points turn on the axes O P R, O Q S, the rotations will measure the values of the integrals

.... $\int \frac{r^4}{a^3} d\theta$, $\int \frac{r^3}{a^2} d\theta$, $\int \frac{r^2}{a} d\theta$, $\int r\, d\theta$, $\int a\, d\theta$, $\int \frac{a^2}{r} d\theta$, $\int \frac{a^3}{r^2} d\theta$ ....., where $r\,\theta$ are the polar co-ordinates of P_1, a is twice the length of O Q, and P_1 is moved round a closed curve.

$$O P_0 = a \,.\, O P_1 = r \,.\, O P_2 = \frac{r^2}{a} \,.\, O P_3 = \frac{r^3}{a^2} \ldots O P_n = \frac{r^n}{a^{n-1}},$$

and $$O P_{-1} = \frac{a^2}{r} . O P_{-2} = \frac{a^3}{r^2} \,.\, O P_{-3} = \frac{a^4}{r^3} \ldots O P_{-n} = \frac{a^{n+1}}{r^n}.$$

For a wheel on the axis O P_1 R, say the wheel at P_n, where n is odd, it is clear that the rotation measures $\int \frac{r^n}{a^{n-1}} d\theta$.

For a wheel on O Q S, say the wheel at P where n is even, the rotation measures

$$\int \frac{r^n}{a^{n-1}} d\phi, \text{ where } \phi = \theta - \cos^{-1}\frac{r}{a}$$

$$d\phi = d\theta + \frac{dr}{\sqrt{a^2 - r^2}},$$

and $$\int \frac{r^n}{a^{n-1}} d\phi = \int \frac{r^n}{a^{n-1}} d\theta + \int \frac{r^n\, dr}{a^{n-1}\sqrt{a^2 - r^2}},$$

the latter integral vanishes round a close curve.

This machine, if it could be constructed, might be applied to the evaluation of any quantity of the form $\int f(r)\, d\theta$, where $f(r)$ can be expanded in powers of r. The well-known extended form of Amsler's planimeter gives the values of $\int \sin\theta\, dx$, $\int \sin 2\theta\, dx$, &c., &c., where x is the distance O Q from a fixed

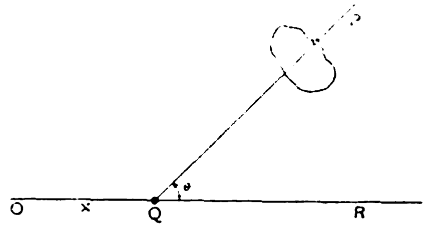

FIG. 2

point O along the straight line, which is the locus of Q, and where θ is the angle P Q R (Fig. 2). Amsler's machine will evaluate any quantity of the form $\int f(\theta)\, dx$, where $f(\theta)$ can be expanded as a series of sines of multiples of θ, the integration being effected round a closed curve.—Yours, &c.,

September 17, 1894. WM. ARTHUR PRICE.

TURNING DOWN THE ELECTRIC LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As you have devoted over a column to "slating" my patents in connection with the "turning down" of glow lamps, I presume you will allow me to reply in a somewhat smaller space.

In the first place, your paragraphs are to my mind somewhat unfair, as they mainly deal with the cutting-off principle, which the *Birmingham Gazette* article expressly states is not suitable for householders, and, generally speaking, your remarks and extracts remind me of the American editor, who, in giving an "extract" from a contemporary merely omitted the word "not."

Now, the commercial value of my patents lies in the switches which switch from parallel to series, and from one series to another series, and require no resistances and no "dead" lamps.

In a bedroom or railway carriage lighted by two 16-c.p. lamps the current passing when full on is (according to your figures, which I will take throughout to save argument) 1·28 amperes; but, when I throw the switch over and alter the current from parallel to series, the current passing is, as near as I can measure, 0·25 ampere, or between one-fifth and one-sixth the current, and between one-fifth and one-sixth the cost, quite exclusive of the extra life given to the lamp.

In cases where one 16-candle-power lamp is considered enough I place two 8-candle-power lamps. Then take the varied series principle. In my cluster of six 16-c.p. lamps I run them when full on in three lots of two series, but when I want a subdued light I turn my switch over, and the following change takes place—all in one movement of the switch and instantaneously—two lamps momentarily go out, and one of them is transferred to one of the remaining pairs, and the other to the other pair; as a result, I get two lots of three series. When full on the ammeter registers 3½ amperes, and when subdued to a pleasant mellow light it registers 1½ amperes, thus showing a saving of four-sevenths in current and money.

Now professors may make what elaborate calculations they like on their blackboards, but practical men will look at this question of £ s. d.

The essence of the invention is this: The power ordinarily consumed by the resistance is reproduced as light instead of being dissipated in heat, and this without altering the number of lamps aglow. Something intended to serve a like purpose has been tried in a clumsy way before by having a lamp not in use when full light is required, but which is switched into series to increase the resistance and reduce the light; but this plan, in addition to its unsightliness, does not reduce the light as much as mine, and uses 100 per cent. more current.

To my mind the ordinary resistance reminds me of a man slowing down his engine by having a blow-off cock on his cylinder.—Yours, &c., THOMAS BUDWORTH SHARP.

THE ALTERNATE ARC.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In some experiments which I undertook a few months back I found that the band of violet light of the usual alternating-current arc lamp could be got rid of, and the efficiency considerably increased, by using a solid carbon for the top and a cored one for the bottom, in place of the two cored ones commonly used. Carboned in this way the arc struck is shortened to a normal length, with the result of an increase of temperature at the points of the carbons, and naturally a whiter light comparing very favourably with the direct-current arc, supposing the current supplied to each is equal.—Yours, &c.,

Bournemouth, September 12, 1894. S. G. BROWN.

THE GLASGOW MUNICIPAL ELECTRIC SUPPLY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your "editorial note" this week you concluded by saying: "We observe the units unaccounted for still amount to 16 per cent. of the total number generated, the figure of the previous year having been no less than 26 per cent. This is probably as much a matter of meters as of mains."

The statement accompanying the report was sent out by the Treasurer, and from the quantity not accounted for has to be deducted the quantity expended on the feeders 73,703 units, on the batteries 12,775 units, and on meter shunts, say, 2,000 units, leaving about 50,000 unaccounted for.

The figures for the previous year relate entirely to the supply from John-street Station. This station supplied an alternating current at 2,400 volts, transforming through Ferranti's 1882 transformers. The current measured through the day averaged about 4 amperes, which was read from an instrument graded to read from 10 amperes. The output of the station was not calculated from this office, so that I do not think comparisons can be made between the two years. Might I call your attention to an error in your statement on page 583. The headings of columns seven and eight are transposed. They ought to read: Number of public lamps, 71 and 102; the per cent., 25·15 and 16·2.—Yours, &c, W. ARNOT.

Glasgow Corporation Electric Lighting Station,
September 15, 1894.

LEGAL INTELLIGENCE.

Thames Electric and Steam Launch Company v. Ernest Scott and Mountain (Limited).

At the Brentford County Court, on Saturday last, before Judge Bagshawe, Mr. W. S. Sargeant, manager of the above Company, sued Messrs. Ernest Scott and Mountain, of Newcastle-on-Tyne, to recover £11. 11s. for work done. The defendants claimed as a set-off £37. 3s. 6d. for work done by them to an engine which had been in care of plaintiff.

Mr. LAMBERT (for the plaintiff) said in November, 1891, the plaintiff received instructions from Mr. Bolton, one of the defendants' agents, to remove an engine from Kew Bridge to his own house, with the object of disposing of it by sale. The engine was consequently removed by Messrs. Woodhouse and Rawson, and by a further order from Mr. Bolton was subsequently removed to Eel Pie Island, where it was found the engine required certain repairs, which were also carried out by an order from Mr. Bolton. The cost of removing and repairing constituted the present claim.

Mr. GROSSER (for defendants) said that the claim was disputed as a whole. As to the counter-claim, the defendants held that the plaintiff had put every obstacle in the way of defendants obtaining the engine, which was not finally returned till July, 1894. The counter-claim was formed of Mr. Winterbourne's account in removing the engine from Eel Pie Island, which was swelled by the obstacles put in the way by defendant, and of repairs necessary to the engine.

Correspondence which was put in contained a letter from the defendant Mountain, who repudiated any liability for the action of Mr. Bolton, which was written, as explained by Mr. Grosser, in ignorance that Mr. Bolton had given any instruction for work to the plaintiff. The defendants were under the impression that the Thames Electric Launch Company were submitting a claim independently of that made by Mr. Sargeant, but Mr. Lambert said that for all purposes Mr. Sargeant was the Company.

Mr. SARGEANT said he sold Messrs. Woodhouse and Rawson his business at Chiswick in 1892; he was their manager when the engine was removed, but he was away at the time. Messrs. Woodhouse and Rawson went into liquidation in 1892 or 1893, after he left them. He did business on his own account while with Messrs. Woodhouse and Rawson. Bolton was asking £225 for the engine, which had never been consigned to Messrs. Woodhouse and Rawson. The demand for the return of the engine in 1893 was made through Bolton. When he left Messrs. Woodhouse and Rawson's he started boat building at Twickenham; that was before the removal of the engine from that firm's premises. He never began to sue Messrs. Woodhouse and Rawson for the delivery of the engine.

After £1. 1s. had been withdrawn from the plaintiff's claim, a verdict was given for the plaintiff on the claim for £2. 10s. 3d. and costs, and for the plaintiff also on the counter claim, without costs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

TENDERS INVITED.—The St. Pancras Vestry require tenders for works in connection with their new central station at King's-road, Camden Town, of which particulars will be found in our advertisement columns. Specifications, &c., can be obtained at the offices of Prof. H. Robinson, 13, Victoria-street, S.W.; and tenders must be sent in to Mr. Albert E. Pycraft, the Chief Clerk, Electricity and Public Lighting Department, Vestry Hall, Pancras-road, N.W., by 12 o'clock on October 11th.

TENDERS ACCEPTED.—The tender of Messrs. Crompton and Co. has been accepted by the Mersey Docks and Harbour Board for an electric light installation at the new coaling jetty, Duke-street Bridge, East Float, Birkenhead; and the Board have given the Liverpool Electric Supply Company (Limited) an order to instal the electric light in the Albert Dock warehouses.

——— The following tenders have been received by the Electric Lighting Department of the St. Pancras Vestry for the supply and laying of armoured cables:—

Reid Bros.	£2,428	17	2
W. T. Glover and Co.	2,339	2	2
W. T. Henley's Telegraph Works Company	2,084	6	6
India Rubber Company	2,084	1	4
British Insulated Wire Company	2,073	6	3
Callender Company	1,872	11	0
Siemens Bros. and Co.	1,812	11	1
Fowler-Waring Cables Company (accepted)	1,750	14	6

——— The Worcestershire County Council have accepted the tender of the New British Installation Contractors (Limited) for the wiring of the County Hall, the Crown-court, the Council Chamber, the offices, and grounds, for the sum of £273. 15s. 4d.

——— The Electric Light Committee of the Town Council have accepted the tender of Messrs. Mackenzie Bros., of Edinburgh, for the supply of 175 arc lamp posts.

——— The Bury Town Council have accepted the tender of Messrs. W. Storrs, Sons and Co., of Stalybridge, for the erection of an electric lighting station.

——— The tender of Messrs. Edwards and Yirrell has been accepted for the erection of buildings for the electric light supply to "The Gables," Linslade, Bucks.

LIQUIDATIONS.—The Official Receiver (Mr. S. Wheeler) has just issued his observations in the matter of the Steam Loop Company (Limited), which was formed in December, 1890, to acquire and work patents for the steam loop designed to secure for steam users economy of fuel and water, and to carry on the business of engineers and tool makers. Liabilities are returned at £1,146, with assets estimated to produce £139, in addition to patent rights which cost £47,900. The Directors of the Company state that they are unable to estimate the value of these patents, and accordingly tenders have been invited for the same from a selected number of engineering firms. The Official Receiver states that there are circumstances connected with the promotion of the Company requiring investigation.

——— A general meeting of Roper's Electrical Engineering Company (Limited) is called for October 15th, at 3 o'clock, at the offices of Messrs. Neill and Holland, 35, Hustlergate, Bradford, to receive an account of the winding up, and a general report from the liquidator (Mr. W. M. Gray).

——— At meetings of the shareholders of Field's "M.P." Development Association (Limited), held on 10th and 29th ult., a resolution was passed and confirmed, winding up the Company voluntarily. Mr. B. Newstead, of 3, Church-passage, Guildhall, E.C., is the liquidator.

BANKRUPTCIES.—The adjourned meeting of the creditors of Arthur Shippey was held at Bankruptcy-buildings, Carey-street, W.C., on Monday last. In the absence of a sufficient number of proxy holders no vote could be taken by the Official Receiver. The debtor asked that his affairs should be wound up, and this was agreed to, and the public examination is to take place on October 2nd at 12 o'clock. The principal creditor (for £3,273) not having proved his claim, his debt was not admitted for voting. The debtor explained that after a few ups and downs he started afresh in 1886 with £50 capital borrowed from his

Digitized by Google

mother-in-law, and he hoped to pay off all his debts when his patents were put into the right channel for developing. He has a brother in America who, he believes, will float him again when he (the brother) arrives in England. He attributes his failure to unrealised assets, and to his inability to pull through a scheme for the electric lighting of Herne Bay. The debtor was adjudged bankrupt in 1882, and then filed a statement of affairs, showing liabilities £1,852, with assets showing an apparent surplus of £5,917. No dividends have, however, yet been paid, and no discharge obtained under these proceedings. He subsequently started in business as an electrical engineer and afterwards sold his business to a limited company, entitled Shippey Bros. (Limited), for £8,000, of which he was to receive £3,000 in cash in six half-yearly instalments, and the balance in shares. He received no cash, but accepted further shares in lieu thereof. The debtor expects that Shippey Brothers (Limited) will shortly be bought out by a new Company, and that then his shares will be of some value. He is now employed as a traveller on commission. The present liabilities, as estimated by the debtor, are £1,170, against which assets, also estimated by debtor, show a surplus of £4,797. No books of account have been produced. A portion of the estimated surplus is dependent upon the sale of certain patents to a limited company now being formed to work them. The debtor has been asked to file a statement of reasons for anticipating a surplus.

——— The first meeting of creditors of W. D. Gooch (*see* last week's *Electrician*) is to be held on the 24th inst., at 11, and the public examination is fixed for November 8th, at 12:30, both at the Bankruptcy Court, Carey-street, W.C.

Receiver Appointed.—Messrs. H. Ward Leonard and Co., of Electrical Exchange-building, New York, announce that they have voluntarily gone into temporary liquidation. Mr. Leonard has been appointed temporary receiver for the New York State assets. The statement of affairs shows assets estimated about $177,000 and liabilities about $62,000. Of the assets $109,000 are locked up in a suit against the Cayadutta Electric Railway Company. H. Ward Leonard and Co. being, according to the law of the United States, subject to attachment, the Directors have deemed it best for the interest of creditors and stockholders to place the Company's affairs in the hands of a receiver until the settlement of the action with the Railway Company, when it is anticipated ample assets will be forthcoming to settle all claims in full and means provided to enable the Company to continue its business.

Appointments.—Mr. F. F. Bennett, of the firm of Bennett and Druce, Preston, has been appointed by the Radcliffe Local Board as their consulting and electrical engineer.

——— Mr. J. B. Mitchell, of Bradford, has been appointed electrical engineer to the Corporation, at a salary of £180 per annum.

Appointment Vacant.—The Brighton Corporation Electricity Works require an electrician for the meter-testing department. Applications must be sent in at once to Mr. Arthur Wright, the manager, Corporation Electricity Works, Brighton.

Changes of Address.—Messrs. J. C. Fuller and Son, telegraph engineers, &c., have removed from 547, Old Ford-road, Bow, London, E., to Woodland Works, Wick-lane, E.

——— The London offices of Palmer's Shipbuilding and Iron Company have been removed to 17, Billiter-buildings, Billiter-street, E.C., and the registered offices of the Company are now at Newcastle-on-Tyne.

——— Messrs. Jeffery, Taylor and Co., electrical engineers, have removed from Tidal Basin, London, E., to city premises at 11, Queen Victoria-street, E.C., where the firm will continue to carry on the business of electrical engineers. Recent installations carried out include the Royal Albert Music Hall, London, E. (the outside lighting by Jeffery arc lamps), as well as a number of installations in the E.C. district.

Tramways for Sale.—By order of Mr. Justice Chitty, the Hull Street Tramways are to be sold as a going concern by private tender. The tramways consist of 16,797 yards of single and double line. There are over 33 cars, rolling stock, freehold land, fixed machinery, &c. Tenders have to be sent in to the chief clerk of Mr. Justice Chitty, at his chambers, Royal Courts of Justice, Strand, London, W.C., not later than the 24th prox.

A New Safety Connector.—The introduction of electrical heating and cooking apparatus has shown the necessity of improved arrangements for connecting and disconnecting the conducting wires from the utensils while in use. The kettles, saucepans, &c., of course, require frequent cleansing, and the wires become damaged if not detached. The ordinary system of using a plug attached to the wire and inserting it in the socket affixed to the apparatus is by no means a perfect arrangement. Protection to some extent is afforded by a ring of metal or porcelain around the pins, acting as a shield; but there are still "live" ends, and a fork or other piece of metal coming in contact with these would probably result in an alarming flash, besides blowing the fuse. The most serious thing would be the banishing of the electrical cooking apparatus from the household on account of these imaginary dangers. To prevent all possibility of accidental contact Messrs. Crompton and Co. are introducing a patent safety connector in which there are no exposed contacts. The usual arrangements for connection are reversed, as the pins (or other plug forms of contact) are fixed on the utensil itself, and are surrounded with a shield of metal to protect them from mechanical injury. The socket attached to the flexible wire is made with the contact tubes sunk well into the base and connected up in the ordinary manner. In front of the socket, and covering the entrance to the tubes, is a fibre or porcelain disc, pierced with two holes for the admission of the pins, and free

Fig. 1.

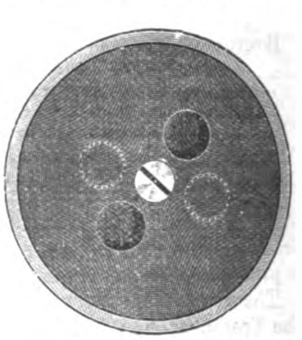

Fig. 2.

to move on a central screw. A spring fixed underneath helps to keep the disc in such a position that the ends of the tubes are always covered. When the pins are inserted in the holes of the disc, contact is not made until a quarter turn is given to the socket, when the pins are allowed to enter the tubes. The action is simple, and is similar to the turning of a key in a lock. Immediately the plug is pulled off the shield springs round, covering the holes and automatically protecting them. The connections are brought to the handle. This prevents the contacts becoming wet and greasy when the utensils are in use, and there is less danger of damage in the cleaning. The working parts of the connector are enclosed in a nickel-plated case, and two milled rings give plenty of grip power. Fig. 1 is a general view of the safety connector; Fig. 2 is a plan of shield, the dotted circles showing the position of the contact tubes below; Fig. 3 shows method of using.

Fig. 3.

The new safety connector can be applied to electric light standards, or, indeed, to any kind of portable fitting, and the necessity of keeping the wire attached is obviated. For floor sockets the safety connector is of service, as loose blocks or plugs are dispensed with when the socket is not in use. The makers are adapting the principle of the safety connector to high tension switches, terminals, and connections, which will be automatically protected, thereby preventing accidental contact.

Portable Ladder Scaffolds.—Messrs. Heathman and Co., of Endell-street, London, W.C., are making a portable ladder scaffold to telescope and adjust at various heights. These ladders are found very convenient for use in cleaning and attending to arc lamps. The ladder is mounted upon wheels, and is thus easily moved about over rough ground, and can be completely managed by one man. The firm have recently made several of these ladders to order, the first being in use at Spitalfields Market, and others have been supplied to the Norwich Castle Museum, the London and North-Western Railway Company, Crewe, and the Great Northern Railway Company. The ladders are certainly a great advance on the old clumsy style of portable ladder.

The Union of Continental Incandescent Lamp Makers.—A list of the members forming this association is, we understand, to be published shortly. The quarterly meeting of the union was held at Frankfort on the 10th, 11th, and 12th inst., when it was announced by the President that communications had been received from several lamp makers who had hitherto kept aloof from the association, intimating that they were prepared to join.

"Architects, Builders, and Contractors' Directory of America."—We have received a copy of "Hendricks' Architects and Builders' Guide and Contractors' Directory of America for 1894-95," which is a complete directory of all the construction industries of that country, and contains over 170,000 names, and is published by the Samuel E. Hendricks Company, of New York,

Digitized by Google

The work is very complete, and provides for the architectural, building, and contractors' industries a valuable means of intercommunication, and is indeed what, as time progresses, the publisher of "*The Electrician* Electrical Trades' Directory and Handbook" hopes to provide for the important industries served by this journal. The science of directory compilation is probably better understood in this country than in any other; but, although this may be agreed, such a work as the one under review is, for lack of encouragement, very difficult of achievement here.

Graphic Wiring Table.—A new graphic wire table has been designed by Mr. A. H. Howard, which shows the dimensions of copper wires and cables in both decimals of an inch and in metric measurements, the equivalent sizes in solid and stranded wires, the fall of potential, the rise of temperature with given amounts of current, and other necessary and useful information, enabling the electric light engineer to see at a glance the best form of mains and conductors he can employ for the work he has in hand. The various wires and cables are arranged above one another in vertical columns according to their area, ranging from 0·001in. to 1 sq. in.; so that all equivalent areas are shown in the same horizontal lines; while diagonal lines give the fall of potential per 100 yards upon any sized conductor, with any current from 1 to 1,000 amperes. A series of curves, printed in red, shows approximately the temperature of any conductor with any given current. These curves are based upon Mr. A. E. Kennelly's experiments for ascertaining the rise in temperature of insulated wires enclosed in wooden casing. A feature in the design is that the divisions are drawn at distances proportional to the logarithms of the areas; instead of being directly proportionate to the areas. The diagonal lines showing the fall of potential are thus made parallel instead of radial, with the result that all parts of the table are equally easy to decipher; the resistances of the several conductors are given in separate columns, at per 1,000 yards and per mile. The weight per mile is also shown. The table is drawn upon a fairly large scale, and is so arranged as to admit of additional lines being inserted to embody any data that may be useful in particular cases, such as the resistance, &c., of iron, platinum, or other metals which are used in electrical work. This table, which is the most complete of the kind that we have seen, will shortly be issued by Messrs. W. T. Glover and Co., of Salford and London.

The Epstein Company.—We understand that the application recently made for subscription to Seven per Cent. Mortgage Debenture Stock of this Company met with fair success. A sufficient amount was subscribed, we learn, to justify the Directors in going to allotment, and, pending the completion of arrangements now under consideration Epstein accumulators are made, under the Company's supervision, by a leading firm of electrical engineers.

Ready Reckoners.—We have received a copy of the third issue of "Reid's Patent Indexed Ready Reckoner," and amongst the many books of this kind in the market the handiness of this ready reckoner is noticeable. It is furnished with a fore-edge step-by-step index of all amounts from $\frac{1}{16}$th of a penny to 20s. 3d. A chartered accountant's certificate is given that the book has been thoroughly overhauled and the figures verified, a by no means unnecessary complement to a perfect ready reckoner. The book is well printed on good paper, strongly bound in cloth gilt, and is published at 2s. 6d. A useful office accessory.

Aberdeen.—At a joint meeting, on Friday, of the Watching and Lighting and Gas and Electric Committees of the Town Council, it was reported that the cost of the electric lighting of Union-street, at 7d. per unit, was £262. 2s. 10d. per annum. The expenditure for gas light over the same area was stated to be £70. 5s. 10d. It was decided that the gas department should supply the current for street lighting at 2½d. per lamp per hour, the Lighting Committee to bear the cost of the carbons and maintenance.——Steam power has hitherto been employed for generating the electric current used in lighting the Monastery at Fort Augustus, but a 45-h.p. turbine has recently been substituted for the steam engine. The water is obtained from the river Tariff, about three-quarters of a mile distant. It is intended to utilise electricity in the Monastery for motor purposes as well as for lighting.

Aberystwyth.—Considerable dissatisfaction was expressed at the last meeting of the Town Council at the delay which it was stated had occurred in the lighting of the town by electricity; but a message was received from Mr. Grant, the contractor, before the Council separated that the works would be ready for testing in three or four days.

Alleged Theft of Telegraph Materials.—On Monday, James Bailey and Charles Sowden, labourers, were brought up on remand at the Plymouth Petty Sessions charged with stealing a quantity of telegraph materials, the property of Her Majesty's Postmaster-General. The material included Leclanché zincs, copper wire, and old Daniell plates. After hearing some evidence the prisoners were again remanded.

Ayr.—The Secretary of State for Scotland has approved the loan of £15,000 proposed to be raised by the Local Authority for the execution of works under their Electric Lighting Order. The Board of Trade have been informed of the system proposed to be adopted for the electric lighting of the town, and as soon as they have approved it the necessary works will be started.

Bath.—At the meeting of the Surveying Committee of the Corporation on Monday, Alderman Bright said he thought the Electric Lighting Company ought to switch on the current a little earlier in the evening for the lighting of the streets. Alderman Sturges explained that the agreement with the Company provided for an average lighting throughout the year of 10 hours for each night. It was found impossible, however, so to arrange the lighting as to make this average cover the hours of darkness all the year through, and he suggested that the complaint should be referred to the Lighting Committee, which was done.——A meeting of shareholders of the Bath Electric Lighting and Engineering Company (Limited), held on Thursday last, adopted a special resolution authorising the Directors to apply to the Board of Trade for a Provisional Order for an extension of the Company's area. It was stated that, while the Local Authority had not intimated their consent to the Company's proposed application, it was not anticipated that they would seriously oppose it.

Blackburn.—The sanction of the Local Government Board has been received to the borrowing by the Town Council of £32,000 for electric lighting purposes, and the Board have also approved of the Corporation using No. 1 gasworks as the site for an electric lighting station.

Blockley (Worcester).—The streets of Blockley have been lighted by petroleum or electricity for 31 years, the cost being raised by voluntary contributions. The committee which have had the matter in charge have now wound up their proceedings, and a public meeting is to be called to arrange for the future lighting of the streets.

Bootle.—The Town Council have resolved to apply for an electric lighting Provisional Order.

The British Museum.—A Parliamentary return just issued says that the artificial lighting of the reading-room has been greatly improved by the installation of incandescent electric lights fitted to the reading desks. The old system of arc lamps is, however, still retained for the general lighting of the room, but at a lower candle-power.

Bromsgrove.—The Local Board have decided to consent to the application of Messrs. Hemming and Co., of Birmingham, for permission to introduce the electric light into Bromsgrove, the Board reserving all legal rights and powers.

Cardiff.—A petition is being signed at Cardiff with a view to inducing the National Telephone Company to place that town in direct telephonic communication with the metropolis. A similar movement in connection with the post-office telephone system has been initiated by the Cardiff Chamber of Commerce.——Dr. Arthur, of London, last week explained to a meeting of the Cardiff Health and Port Sanitary Committee a scheme for dealing with house refuse, by which a large portion of the refuse would be utilised for lighting the town by electricity. The Committee are awaiting further information.——At a meeting of the Lighting Committee of the Corporation on Tuesday last, the question was introduced of the provision of small motors, which would probably be used by tradesmen if they could be rented at a moderate outlay. The Borough Engineer agreed that the question was a practicable one, as it was to the interest of the Corporation to have as much electricity used during the day as possible, but the subject was eventually deferred for further consideration.

Carlisle.—The Gas Committee of the Corporation have instructed the manager to make inquiries in reference to the notice given by the Brush Provincial Company that they would apply for a Provisional Order.

Chapel Lighting.—The electric light has been installed in the Waltham-street Wesleyan Chapel, Hull, the work having been done by Mr. Blanchard, of Whitefriargate. There are 18 electroliers of wrought iron, specially designed to suit the building, and carrying from three to twelve lamps. The three-wire system has been adopted.

Chester.—Complaint was made at the last meeting of the Town Council of the dilatoriness of the Electric Lighting Committee, but it was stated that the Committee were still engaged in seeking a suitable site for a generating station.——A special meeting of the Town Council was held on Wednesday, when, after some discussion, the recommendation of the Electric Lighting Committee that the Water Tower Gardens, belonging to the Corporation, be the site for the proposed electric light station, and that the Committee be authorised to proceed with the establishment of the installation, was adopted.

Colliery Managers' Association.—The annual gathering of the members of the National Association of Colliery Managers was

Digitized by Google

recently held in the Forest of Dean at the invitation of the south-western branch of the Association. Mr. F. W. T. Brain, general manager and secretary of the Trafalgar Collieries, who is the president for the ensuing year, and who occupied the chair, delivered an interesting address, in which he referred with satisfaction to the financially sound condition of the Association. A considerable portion of the Chairman's address was devoted to the subject of the wages disputes in the coal trade, and to the probable effect of an Eight Hours Bill on the mining industry. Reference was then made to the recent explosions attributable to the accumulation of coal dust, and the effect of shot firing thereon. The cost of the electric fuses, which were now so generally used for shot-firing purposes, and were so emphatically recommended by H.M. Inspector of Mines and also by the Prussian Commission for the safe and efficient firing of all explosives, would be found to be somewhat higher than that of gunpowder. This extra cost was very largely due to the limited number of fuses used, but he looked forward to a much increased consumption which would bring about a reduction in the cost. With regard to the employment of electricity in mining he (the president) had but a short time left him for dealing with this important subject. That electricity would be largely applied to mining work in the near future he was convinced. With three electric pumps working underground in the collieries with which he was connected, the first one of which had been running since 1882 (and this was, he believed, the first known application of electricity to mining work), he could speak with confidence as to its utility. So satisfied were the proprietors of the Trafalgar collieries as to the advantages afforded by electricity that they were now putting down an extensive system of underground main and tail rope haulage of about 150 H.P., costing several thousand pounds, and he hoped at some future time to be able to place before the south-western branch of the Association a description of the plant. Electricity, applied to pumping, hauling, and coal cutting, was now in constant work in several parts of the country. With the improvements now being introduced its use would become much more general, and even now scarcely a week passed without particulars being published of new electric plant in connection with mining. So far as mining was concerned, the application of electricity had passed from the experimental to the practical stage, notwithstanding considerable initial difficulties, and he regarded its future use as assured. Mr. Brain's remarks on this subject met with the hearty endorsement of the members of the Association. The members subsequently visited Mr. Simmonds' limestone quarries at Edge Hills, to witness one of the largest blasts on record, in which four tons of gunpowder were exploded. Everything passed off satisfactorily. These operations were carried out under the management of the Electric Blasting Apparatus Company, of Cinderford, in presence of between 6,000 and 8,000 persons, who lined the hills in the neighbourhood. By this explosion it was calculated that about 36,000 tons of rock had been displaced. A banquet was subsequently held under the presidency of Mr. Brain, at which the toast of "Success to the National Association of Colliery Managers" was proposed by Mr. T. Forster Brown, who stated that in his 30 years' residence in the district of the Forest of Dean he had frequently been brought into contact with the Chairman and his brothers, the former of whom had done yeoman service as one of the earliest pioneers in the application of electricity to practical purposes, and they were proud of his success in that direction. Subsequently the members visited the Trafalgar Collieries to inspect the new electrical machinery and appliances recently erected, and referred to in the president's address. The machinery for this important work was put down by Messrs. Easton, Anderson and Goolden (Limited), and the installation is so thoroughly complete that it even includes a telephone service. The electrical operations are worked from the top, and the telephone system connects up the engine house, the haulage engine room, and the extreme point on the roadway. A visit was afterwards made to the Electric Blasting Apparatus Company's fuse factory, in the inspection of which the members were much interested; and, finally, the members were invited to a public reception at Coleford, which brought the function to a pleasant conclusion.

Country House Lighting.—Lord Burton is extending the electric light at Rangemore Hall, near Burton-on-Trent, and new machinery for 1,000 lights is being put down under the direction of Messrs. Massey and Allpress. The same firm are also rearranging a very large electrical plant for Lord Windsor, at Hewell Grange, near Bromsgrove.——Messrs. Drake and Gorham have been entrusted with the lighting of Mr. J. T. Smithe's house at Eveley. There will be about 100 lights, and the power will be derived from a water turbine driving a 5-unit E.C.C. dynamo. Fifty-three D.P. cells will be fixed, capable of supplying current to 58 16-c.p. 60-watt lamps for nine hours or over 90 for four hours.

Dublin.—Messrs. W. Curtis and Sons, of Abbey-street, have secured the contract for the electric lighting of the new Parcels Post Depôt. Concentric wiring has been adopted, and the work is to be carried out under the direction of Mr. J. Howard Pentland. The total effective candle-power to be provided for is about 7,000.

Derry.—An adjourned special meeting of the Lighting Committee of the Town Council was held on Tuesday, at which the animated discussion on the subject of the electric lighting cables was resumed. A letter was read from Dr. J. Hopkinson, dated February, 1893, in which approval was given to the specifications and drawings prepared by Mr. Blake, the Corporation's electrical engineer, for the cables. From the remarks made at the meeting it would appear that litigation is, unfortunately, about to be entered upon, and many of the comments made at the meeting were, therefore, better left unreported until the parties concerned have an opportunity of explaining the position. Mr. Crawford M'Cay, the solicitor, pointed out that it was unwise for the members of the Council to step in between Mr. Blake, their engineer, and the contractors.

——— At the meeting, on Friday last, of the Londonderry Port and Harbour Board, a letter was read from Dublin Castle intimating that the veterinary department would agree to the inspection of cattle previous to shipment being carried on at the port, if the Commissioners provided suitable electric light. The light should be of a certain intensity, and the lamps should be so fixed as to obviate the casting of a shadow, and they should be 11ft. from the ground. After some discussion, the secretary was directed to write to the Corporation inquiring whether that body would be able to supply the electric light at the cattle pens and, if so, upon what terms.

Electricity in the Dairy.—At Blythwood, Stanstead, on Wednesday, Mr. and Mrs. James Blythe entertained the British Dairy Farmers' Association to an exhibition of their "electric dairy." This is a picturesque building, and was opened by the then Lady Mayoress of London in 1892. It is lighted throughout by electricity, and the creamers and separators, churns and other dairy machinery are driven by electric motive power. The exhibition afforded much interest to a distinguished body of visitors, including the Lord Mayor of London and the Agents-General for South Australia and British Columbia.

Fermoy.—The Fermoy Town Commissioners at their last meeting expressed great dissatisfaction with the gas lighting of the town, and decided to take immediate steps to ascertain the practicability and probable cost of introducing electric lighting.

Factory Inspection.—At the concluding meeting of the Associated Chambers of Commerce last week, the following resolution was passed:—"That where factory inspectors propose to inflict new special rules for any manufacturing trade, such rules should be submitted to the local Chambers of Commerce, and copies also sent to the London and other chambers, in order that concerted action may be taken to prevent undue interference with trade." It is in the power of the Chamber of Commerce to effect considerable improvements in the present method of factory inspection. One of the most serious complaints made against the Factory Department of the Home Office is that its inspectors appear to discharge their duties in a haphazard way. So soon as a change of inspectors takes place the new man considers it his duty to at once undo the work of his predecessor, and in many cases calls upon factory and workshop owners to effect radical changes at considerable expense. This is particularly noticeable in the fencing of moving machinery. What is deemed sufficient by one inspector fails to impress his successor, who immediately sets to work and suggests considerable modifications at the expense of the owner. It is not at all an uncommon experience to find that the rules carried out in a factory for years have, on the advent of a new official, to be set aside and fresh rules adopted.

Fareham.—A special meeting of the Local Board was held on Thursday last week to receive the arbitrators' award in connection with the purchase by the Board of the undertaking of the Fareham Electric Light Company (Limited). The arbitrators, Dr. J. A. Fleming and Mr. A. H. Preece, reported that they had carefully examined the building and plant belonging to the Company, and they estimated the value of the undertaking as a going concern, comprising the whole of the plant, machinery, electric cables and stock as scheduled in the inventory of the property of the Company, to which reference is made in the draft agreement between the Board and the Company, at £4,866. 3s. This sum does not include the value of the Browett-Lindley vertical engine and of the self-exciting alternator, which are in the electric light station, but not included in the above valuation. The Chairman, after reading the report, submitted an estimate of the expenditure which would be necessary for the purchase of the undertaking, as follows:—Purchase money to be paid to the Company, £4,886. 3s.; purchase of the site of the station and additional adjoining land, £700; for laying the wires underground and supplying an additional engine, £1,000; cost of electrical adviser and arbitrator, £175; purchase of 7/18th wire, instead of 3/18th, as recommended in the specification, £120. A proposition was then made that application be made to the Local Government Board for sanction

Digitized by Google

to borrow £7,000 for the purpose of purchasing the Company's undertaking, and, after a lengthy discussion, it was carried by 4 votes to 3.

FELIXSTOWE.—The Felixstowe and Walton Local Board have decided to open negotiations for the purchase of the local gas and water undertakings. It was stated at the meeting that if the offer of the Gas Company were not satisfactory, sufficient surplus power could be obtained from the two engines used in the sewage works to light the town by electricity.

FREE LABOUR.—A report of the executive of the National Free Labour Association states that of the 9,786,073 male persons of 20 years of age or over who are working for their living in the United Kingdom, only 1,109,014 are members of trade unions. Referring to the result of the attitude assumed by the leaders of the various seamen's associations, the report states that the result of the aggressive attitude taken up by the men's leaders has been that Southampton, Plymouth, Cardiff, Dublin and Hull have been converted into free labour ports. A manifesto accompanies the report, in which reference is made to the feather-brained resolutions passed at the recent Trade Union Congress at Norwich.

FULHAM (LONDON, S.W.).—The Vestry have instructed the Town Hall Committee to at once consider the advisability of installing the electric light in the Town Hall, in order to prevent the new decorations being spoilt by gas.

GERMAN TRADE MARK LAW.—The new German trade mark law comes into operation on the 1st prox. Under this law all previously recorded marks must be entered on the Imperial register at Berlin, and the first applicant secures priority. Marks which have previously been registered at Leipzig, unless re-registered, will be disregarded by the Berlin officials when dealing with new applications. Infringers of registered trade marks are liable to fine and imprisonment, and to pay an indemnity to the duly registered proprietors. The British Trade Protection Office, Monument-chambers, London, E.C., will give any further information required on the subject.

GOVERNMENT OFFICES.—The electric light is to be installed in the Cabinet Chamber, at 10, Downing-street, the residence of the First Lord of the Treasury, by the time the next Council is held there next month.

GRANGE (LANCASHIRE).—The Local Board have appointed a subcommittee to act with those appointed by other local authorities in the district, with the view of combining in the opposition to the proposed application for a Provisional Order of the Windermere and District Electric Supply Company (Limited).

HAMMERSMITH.—The Vestry have instructed the Town Hall Committee to report on the cost of lighting the Town Hall by electricity.

HERTFORD.—In 1891 the Corporation obtained a Provisional Order for supplying electricity within their district. An electrical engineer was appointed, who prepared plans and estimates for a suitable installation, which was at the beginning of last year reported favourably upon by Prof. Forbes. The Lighting and General Committee of the Council have circularised the inhabitants with a view to ascertaining the probable extent to which the current would be taken, and a special meeting of the Corporation was called for the 24th ult., for the purpose of carrying out the scheme, but was adjourned for a fortnight in order that the ratepayers might have an opportunity of acquainting themselves with the details. Previous to the adjourned Council meeting a public meeting was held, as was reported in our last issue, when a resolution adverse to the scheme was carried; but, at the special meeting of the Council held on the 7th inst., a resolution proposed by Alderman Shelly, "that the electric lighting scheme proposed by the engineer, extended so as to supply the Hertford General Infirmary, be carried out as speedily as possible," was carried, after an adverse amendment had been lost, by the casting vote of the Mayor. The Council then further instructed the engineer to prepare, with the assistance of the surveyor, the detailed plans for carrying out the scheme and the requisite forms of tender for the several sections of the same, and it was also decided to apply to the Local Government Board for their sanction to a loan of £6,000 for electric lighting purposes.

HOVE.—The new baths and laundry, which were opened last week are lighted throughout by electricity, and each bath is fitted with an electric bell.

LEEDS.—For some time past the noise and vibration caused by the electrical plant in the basement of the Municipal Buildings has been a source of discomfort to those engaged on clerical work in the building, and in February last the city engineer was instructed to prepare a report upon the question of the removal of the plant to one of the refuse destructor buildings, it being thought that the waste energy of one of these places could be utilised. The city engineer submitted his report to a meeting of a special sub-committee of the Corporation on Thursday last. He thought that the cheaper and better course to be adopted would be to do away with the generating plant, and to take the current from the mains of the Yorkshire House-to-House Company. After a lengthy discussion the committee resolved to recommend the Council to adopt this suggestion.

LLANDUDNO.—The Llandudno Improvement Commissioners have resolved to apply for a Provisional Order to light the town electrically.

MILL LIGHTING.—The new roller mills at Barton Mills, near Mildenhall, and Messrs. J. Smith and Co's. new roller mills at March have been lighted throughout by electricity; the work having been executed by Messrs. W. J. Crampton and Co., of Cambridge and Yarmouth.——Messrs. Baxendale and Co., of Manchester, are installing the electric light in the Hillsteads and Cinderhill Mill, belonging to Messrs. Bancroft and Co., of Todmorden.

MOSS SIDE.—At the meeting of the Moss Side School Board on Tuesday, a report was presented showing the comparative cost of lighting the new schools by gas and electricity, and, on the recommendation of the Sites and Buildings Committee, it was decided to adopt electric lighting, and the Clerk was instructed to advertise for tenders for the work.

RADCLIFFE (LANCS.).—At the last meeting of the Local Board, a recommendation of the Electric Lighting Committee was adopted that Mr. Bennett be instructed to prepare plans for an electric light installation, in the first instance of not more than 6,000 8-c.p. lamps, and that the works be laid out in such a manner as to enable the Board to make future extensions. If it be decided to proceed with the electric lighting after a Provisional Order has been obtained, Mr. Bennett will be appointed to carry out the works in accordance with terms submitted.

RAILWAY STATION LIGHTING.—A magnificent pile of buildings has just been completed for the Terminal Railroad Association of St. Louis, Mo., U.S.A., for which, with the exception of heating, electricity has been utilised throughout. The building sheds and tracks are lighted, the elevators are run, the station is ventilated, the temperature, time, and watchmen's clocks are regulated, and the signals are throughout governed, by electricity. The electrical plant is considered one of the most complete in the States.

SHOREDITCH (LONDON, E.C.).—The scheme for combining an electric light installation, refuse destructor works, and public baths suffered a practical defeat on Tuesday, when the Vestry, by a majority of seven, postponed for six months the appointment of an electrical engineer.

SOUTHPORT.—At the last meeting of the Town Council, Councillor Holland asked if it was the intention of the Gas and Electricity Committee to have the Promenade illuminated with the electric light. He said that other towns, notably Blackpool, were before them in this respect. Alderman Haeking, the chairman of the Committee, said, however, that there was no present intention of having the Promenade so illuminated.

STIRLING.—A special meeting of the Town Council, at which the question of applying this year for a Provisional Order for lighting the borough by electricity was discussed, and it was agreed to proceed with the application to the Board of Trade.

TAUNTON.—At the monthly meeting of the Town Council, held last week, the report of the Electric Lighting Committee was presented, and, after some discussion, was carried by 18 votes to 1. The Committee reported that they had carefully considered the subject of various extensions to the electric lighting system, and that these extensions have been approved by Dr. Fleming, the consulting electrical engineer. The Committee therefore recommend that the following extensions be carried out, and that application be made to the Local Goverment Board for sanction to borrow £5,000 for the necessary works, this sum to be repaid within a period of 30 years:—

	Estimated cost.
At Sub-station No. 2 (St. James-street)	£1,450
Sub-station No. 3 (to be constructed under the road at Eastgate)	1,500
Coal shed, weighing machinery, and other works at the generating station	300
A new boiler, large engine, dynamo, and other works	1,750
Total	£5,000

VICTORIA STATION (MANCHESTER).—The Lancashire and Yorkshire Railway Company are making important alterations at this station, on both the western and eastern sides, which are estimated to cost about £200,000, irrespective of the cost of land acquired for the extensions. When completed the whole of the offices, which cover a large area, are to be lighted throughout by electricity.

WEMBLEY TOWER.—It is expected that this tower will be completed up to the first platform within three months. The platform is at a height of 155ft., and this portion of the tower is upwards of an acre in extent. The extent of country over which the beauty of the landscape is destroyed is upwards of fifty square miles.

WIGAN.—At a meeting, last week, of the Gas Committee of the Corporation the report of the Electric Lighting Sub-Committee was

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 854. VOL. XXXIII. FRIDAY, SEPTEMBER 28, 1894. PRICE FOURPENCE Annual Subscription (U.K.), 19/6

NOTES.

MUCH interesting and useful information in regard to car and train brakes in general, and electric brakes in particular, is to be derived from the Paper by Mr. E. A. SPERRY, an abstract of which we publish this week. Accurate data respecting the best practice in the design of brake blocks and of brake levers is by no means as plentiful as might be desired, and Mr. SPERRY's researches form a material addition to our stock of knowledge on the subject. Engineers, as a rule, have had to design brakes on the rough-and-ready principle of providing a large allowance for unknown coefficients wherewith to meet unforeseen contingencies. Hitherto the chief difficulty has laid in the limited amount of retarding force which has been available before the wheels commence to skid, a difficulty which, as far as purely mechanical remedies are concerned, can only be surmounted by putting brakes on a sufficiently large number of wheels. The moment skidding commences the rail friction diminishes, and the train slides on against a reduced retarding force. A bad result is flats on the tyre. Mr. SPERRY shows that, with the electric brake, the consequences of skidding can be avoided, and even skidding itself need take place only momentarily. For the force of the electric brake depends on the fact of the wheel rotating, and is proportional to the speed of rotation. The moment there is any tendency to skid, the brake relaxes its grip and allows the wheel to roll. Of course, what really happens is that the brake adjusts its force so as always to keep the wheel rolling. The effect might even be enhanced, and the retarding force of the brake be considerably raised above the value of the normal adhesion, if the rail friction itself were magnetically increased. Another valuable feature in Mr. SPERRY's system of electric brakes is the operation of all the machinery by means of one handle. The act of throwing off the trolley current applies the brakes, and the act of releasing the brakes applies the trolley. This cannot fail to ensure efficient service, by minimising the number of duties of the motorman.

BUT Mr. SPERRY, although careful of the nerves of the motorman and of the lives of pedestrians who may stroll on to the track, appears to be less anxious to please the passengers inside the car. "It may not be known," he says, "that under proper and standard conditions any car or train may be brought from a speed of 10 miles an hour to absolute rest inside of 10ft." We hope we may never be inside any car or train at the moment such an extraordinary feat is attempted. The retardation under these conditions is no less than 11·5ft. per second per second; ten times greater than is usual in practice, and exceeding one-third of the value of *g*. It could not fail to give the passengers a very bad jolt indeed. Nor is it any more comforting to the passenger to be told that the intensity of application of the brake force "should be greatest when the speed is greatest, and decrease as the speed drops off." This, again, is the very way to produce a nasty jolt; and, though it may be quite correct from the point of view of the man who is on the verge of being knocked down by the car, it is likely to raise more than a mild protest from the passengers.

IT was recently observed in one of our Notes that a year or two ago there were a number of attempts at making "dry cells, a misleading name for a rather untrustworthy battery." It is hardly necessary to add that these attempts were prompted by actual success in this direction, and it was to the ineffectual imitations rather than to the satisfactory batteries that we alluded. Among the valuable and original features of Mr. J. T. SPRAGUE's "Electricity" was a table of "The Suitability of Cells." Eleven cells and thirteen uses were enumerated, and a classification was made of the suitability. To draw up a complete table of this kind, well up to date, would be a difficult task; but we are disposed to think that the secret of a thoroughly successful cell would be a clear statement of the purposes for, and conditions under, which it should be used. If these purposes, are numerous, and the conditions liberal, the success should be wide; if, on the other hand, they are limited, the success of the cell, though complete in its way, would be restricted. Many a cell has been condemned because the purchaser has used it for work for which it ought not to have been employed.

BESIDES the conditions under the control of the purchaser, the effect of storage of a stock of dry cells, either under the maker's supervision in his warehouse, or by a, perhaps, ignorant and careless agent, must be considered. A wet cell is dry enough before it is sold, and is liable to no deterioration; but a dry cell, paradoxically, contains a certain initial amount of moisture, and both the storage before sale and the use after sale may alter it. If this moisture is under the observation and control of the user, and can be restored by him when necessary, as in the Leclanché-Barbier cell, alteration in the dryness, by which, of course, we mean the wetness, need not lead to the

Digitized by Google

throwing away of a cell as useless, when there is really plenty more work left in it. The last new dry cell is the Obach, and is manufactured by Messrs. Siemens Brothers and Co., who have already had some experience of this kind of battery. Further particulars will be found in another column. Tests of dry cells, like tests of secondary batteries, do not give very much information unless they extend over a considerable period and under varying conditions. A cell may work a telegraph line for a couple of years with perfect success and without attention, but if left standing on a shelf for half that time it may be apparently or actually worthless. A dry battery is more or less a pig in a poke, and if, after use, abuse, or no use, it appears to be useless, it would be convenient to be able to ascertain whether the poke contains any more pig.

A writer in an American contemporary calls attention to the fact, which is evident to anyone who thinks carefully about the matter, that in scientific measurement the directly observed quantity is often altogether different from the quantity to be measured. Indeed, there are very few physical quantities the magnitudes of which are capable of direct measurement, for the number of physical quantities which can be directly observed is very limited. It would be an interesting study to analyse all physical measurements into their ultimately observed factors, analogous to resolving physical quantities themselves into length, mass, and time. Temperature, for example, is a function of matter which can never be directly observed, and which is always measured in an indirect and roundabout fashion. The common thermometer indicates temperature in terms of a length; other thermometric instruments measure it in terms of observed variation in the volume or pressure of a gas, in the rate of flow of heat energy, or in the change in the electrical properties of a conductor. Temperature in itself is probably as impossible of direct measurement as it is of direct observation; except, perhaps, in the phenomena of ultra-gaseous matter, where the direct observation of molecular velocity would, of course, be identical with the direct measurement of the square root of the temperature. This fact by no means tends to clear away the mist which enshrouds, not the idea of temperature itself, but the conception of it in terms of the fundamental physical ideas. Hitherto, all attempts to define the "dimensions" of temperature have proved futile, based as they always have been upon artificial and strained conceptions of the phenomenon. There is ever some quantity which has to be suppressed, but whose suppression cannot be defined in terms of the already suppressed quantities.

In the matter of the atomic weight of carbon, inductive science is poised on the horns of an instructive dilemma. The instruction is not merely to chemical science alone, but may be assimilated by all branches of physical science and research. On the one hand, chemists have been accustomed to argue the atomic weight of an element from the series of compounds which it forms with other elements, on the principle that there can be no half atoms. The lowest integer is taken as indicating the atomic weight. Prof. Wanklyn has recently applied this method to a series of hydrocarbons, and has found that the atomic weight of carbon cannot be 12, but is only half that value. On the other hand, Mendelejef classified the elements into associated groups, on the principle of the periodic law, and a wonderful harmony was the result. Carbon fell at the extreme tip of one of the harmonic curves —as will be seen by reference to Prof. Crooke's diagram, in the *Proceedings* of the Institution of Electrical Engineers, Vol. XX., p. 46—this element being tetratomic and paramagnetic, and standing at the juncture of the electro-positive and electro negative elements in the first half-cycle. This is what happens if the atomic weight of carbon is 12. But if it is 6, the position of this element is shifted, not only out of the first harmonic cycle, but out of every possible cycle; and the periodic law tumbles to pieces like a castle of cards. The dilemma is all the more interesting and instructive from its having been reached by the inductive method. Which is the way out of it? At all events, it teaches us to walk warily, and it reminds us that the "logic of facts" is only unanswerable when all the facts are known and rightly interpreted.

Cable Interruption and Repair:—

	Date of Interruption.	Date of Repair.
Benguela-Mossamedes ...	September 16th. ...	September 26.
Zanzibar-Mombasa	September 4th. ..	--
Macao-Hong Kong	September 25th. ...	—

University College, Nottingham.—The next session of this College begins October 8th.

Gas and Electricity at Biarritz.—A central electric lighting station is being established at Biarritz by the local gas company.

Books.—Messrs. Whittaker and Co. will, in a day or two, publish a new issue, in one volume, of "Electric Lighting and Power Distribution," by W. Perren Maycock, M.I.E.E.

Charges for Electric Power in Berlin.—The Berliner Elektricitätswerke have lowered the price of power for industrial purposes to twopence per kilowatt-hour, from October 1st.

Durham College of Science.—The calendar for the session 1894-95 is now ready, and contains a full syllabus of the subjects to be taken during the session. The day classes include electrical engineering, and the evening classes telegraphy and telephony.

Traction Current in a Telephone Network.—An alarming accident is reported to have happened in Havre on August 15th. The workmen engaged in putting up the telephone wires let a roll of wire fall. All the telephone wires in the quarter of the town were promptly burned up; the wire had tumbled across an electric tramway cable.

The Telegraphists' School of Science.—We have received the list of successes and prizes secured by students in the Telegraphists' School of Science during the last session. The progress in this respect is well marked, the number of successes on this occasion being 159, as against 99 and 66 on the two previous occasions. This institution, under the able direction of Mr. Slingo, aims at the instruction of telegraphists and telephonists in all that is essential to the proper performance of their duties.

The Proposed Berlin Elevated Railway.—The Berlin Municipal Council have agreed to the proposal for the construction of an elevated electric railway. There is little reason to believe, says *The Times* correspondent, that any further obstacles, financial or otherwise, will hinder the execution of this scheme, which those who are fitted to judge have declared to be necessary in consideration of the enormously-increased traffic in the capital. The work will be entrusted to the well-known firm of Siemens and Halske.

Electric Locomotives in France.—According to the *Engineer*, the Paris, Lyons, and Mediterranean Railway Company is now building three types of locomotives—the first series comprising 40 compound engines; the second, 60 electric locomotives, each capable of drawing 800 tons at a speed of 24 kilometres = 15 miles per hour; and the third, electric locomotives, the motor for which is mounted on the rolling stock.

Compressed (?) Air Cars.—An accident has occurred on the tramway, worked by compressed air, which runs between the Church of St. Augustin on the Malesherbes and the Cours de Vincennes. The reservoir in the under part of one of the cars burst. The passengers, who were naturally in a state of great alarm, escaped uninjured. This new line, which is one of the longest in Paris, traverses the city from west to east, and has been working for nearly a month.

The Electrical Resistance of Manganese Steel at High Temperatures.—At a recent meeting of the Académie des Sciences a Paper was read on "Manganese Steel," by M. H. Le Chatelier. The anomalous results found previously by the author in studying the electric resistance of—13 per cent.—ferro-manganese were explained by the formation of two allotropic varieties of the metal. The temperature of transformation is 740deg., that temperature at which soft iron passes from the magnetic to the non-magnetic state.

New Cable between Cuba and the Bahamas.—The Cuban journals announce that the commission appointed to consider the project of connecting Cuba with the Bahamas by submarine cable have recommended the Government to grant a concession to Don Jose Declaux to lay a cable from Havana either to the Andros Islands, Eleuthera Island or Abaco Island, in the Bahamas, or to the Turk Islands, whichever should prove the better suited for putting Cuba in telegraphic communication with the United States, the Bermudas and the Azores.

A Course of Military Electro-Technology.—An Imperial decree has recently been published in Russia ordering the formation of a military electro-technical school, for the purpose of preparing officers of the Engineers to carry out any military electrical work that may be necessary, to train the privates of the Engineers in electrical duties, and to investigate electrical discoveries and inventions likely to be of use for military purposes. The officers' course will take two years, and the maximum number of officers being instructed at the school at any one time is to be 70.

Briquettes.—The bind used in the recent experiments at a Cumberland colliery with a view of making coal briquettes without admixture of pitch or lime is, says the *Engineer*, partly a waste product, the remainder costing on an average from 20s. to 28s. per ton, according to yield and demand. From 4½ per cent. to 5 per cent. of the bind is added to the coal, and a briquette is obtained which neither cracks or crumbles, but which burns freely in an ordinary fire, or under steam boilers, either with or without forced draught, leaving no slag or clinker. The tenacity of the bind is stated to be such that it permits the moulding of briquettes 4in. by 2½in. by 1½in.

Chicago Exhibition.—The Chicago Exhibition awards have been a fruitful source of controversy from the beginning. The latest dilemma is somewhat amusing. According to a Dalziel telegram from Rome, a difficulty has arisen concerning the publication of the official list of prizes obtained at the Chicago Exhibition by Italian exhibitors. The grand jury having awarded two prizes to the Pope, the Italian Government is placed in the dilemma of either comprising them in their list, in which case Leo. XIII. would appear to be treated as an Italian subject, or leaving the name of his Holiness out of it, thus ignoring the distinction conferred on his two exhibits, and making the publication incomplete.

A Short-Circuited Trolley Car.—The passengers in a Baltimore trolley car had, says the *Western Electrician*, an exciting experience on a trip through South Baltimore a few days ago. It appears that the car was proceeding at a rapid rate, when the trolley wire broke, and before the speed of the car could be checked the wire became badly entangled about it. The car, still on the rails of course, thus became a portion of the short-circuit on the line. The woodwork of the car caught fire in several places and sparks could be seen in all directions. After a time the motorman succeeded in stopping the car, but not before the thirty passengers had been thrown into the wildest state of excitement. After it was all over, however, it was found that no one was seriously hurt, although there were bruises and torn garments in abundance.

French Telegraph Rules and Regulations.—There is a general and justifiable outcry against the Posts and Telegraphs Department and its manager, M. de Selves, says the Paris correspondent of *The Times*. The Department recently gave notice that any telegram not fully addressed would be displayed at the telegraph office instead of being delivered, unless the recipients paid 40fr. a year for registering their addresses. Hitherto telegrams to newspapers have been addressed simply "*Débats*, Paris," and so on, for the whereabouts of their offices could not but be well known. If, however, every telegram had to be addressed, say, "*Times*, 35, Boulevard des Capucines, Paris," the extra four words would cost from 20 to 80 centimes extra, and the registration fee of 40fr. was therefore practically obligatory. The object of this vexatious rule was evidently to increase the receipts of the Department; but the outcry is such that it will doubtless have to be rescinded.

Finsbury Technical College.—At the Finsbury Technical College the autumn courses of lectures and laboratory work begin next week. On Mondays Prof. Silvanus Thompson will deal with alternate currents through the month of October, and in November will give four special lectures upon modern alternate-current motors. The Wednesday evening lectures (elementary course), after the introductory discourse by Prof. Thompson, will be taken by Mr. Eustace Thomas until November, when Prof. Thompson will take up measuring instruments. The laboratory courses remain, as heretofore, under the charge of Mr. E. A. O'Keeffe. The electro-plating laboratory class, under Mr. Rousseau, will meet later in the session. Prof. Thompson's special course of lectures on central stations for electric lighting are to be given on Thursdays at 7.30 p.m., commencing October 4th. Particulars of these courses are to be obtained from the College Registrar.

Physical Society.—The meetings of this society will henceforth be held on the same day and at the same hour as heretofore (Fridays, 5 p m.), in the rooms of the Chemical Society in Burlington House. All communications to the secretaries or other officers of the society may in future be addressed to Burlington House, or to the secretaries at their respective addresses as given in the list of members of the society. The Council have also decided to initiate the publication of a series of abstracts of Papers on Physics. The slender resources at their command make it necessary to begin cautiously. At first abstracts will only be given of Papers which appear in a certain number of the more important foreign magazines. They will be published regularly at the beginning of each month in the form of a supplement to the *Proceedings* of the Society. The first number will be issued in January, 1895. Should the scheme prove successful it is intended to enlarge its scope. The abstracts will for a time be edited by Mr. Swinburne.

Coast Communication.—The Hamburg-American Steamship Company's steamer "Steinhöft," Captain Busch, bound from Hamburg for Montreal, went ashore on the coast of Devon early on Saturday morning on a sandy beach half a mile eastward of Torcross. The coastguard promptly sighted her and signalled, and as the tide was falling, with little sea running, they were able to communicate with the ship. There being no immediate danger, no one landed, but the rocket apparatus was got ready for instant use. Unfortunately the Torcross and other coastguard stations are not connected by wire with Plymouth or any other telegraph station which is always open, and thus a horse had to be procured and a messenger despatched to gallop ten miles in the darkness to Dartmouth, whence a steam-tug was despatched. The tide having risen, the "Steinhöft" was, with the aid of the tug, got off about ten o'clock, having been fast about seven hours. She did not appear to have suffered material damage and proceeded westward. Had an ordinary sea been running, the delay of assistance, owing to the absence of the long-promised telegraphic communication, would probably have had very serious consequences.

Displacement Currents.—Two methods for the study of currents in open circuits and of displacement currents in dielectrics and electrolytes, were recently described by M. de Nicolaïeff before the Académie des Sciences. Discs or rings of dielectrics are, in the first method, supported by bifilar suspension between the two poles of an electro-magnet, so that the plane of the ring is at 45deg. to the axis of the electro-magnet, and centrally situated between the poles. The difference in the displacements caused in constant and alternating fields of the same strength is due to a secondary field set up by displacement currents caused in alternating fields. Paraffin shows an increase of 12 per cent. for a period of 930 per minute, and 9 per cent. for 770 per minute. In the second method, displacement currents in the rings are caused by the iron in the magnet cores. The ring is suspended perpendicular to the axis of the cores; the polar faces can be brought nearer to or removed farther from the parallel faces of the ring. By this method, augmentations have been obtained of 15 per cent. for yellow wax, and 8·3 per cent. for paraffin. Electrolytes in annular glass tubes behave just like perfect dielectrics, sulphuric acid giving an augmentation of deviation of 15 per cent.

"British" Electricians.—"In attempting to avert German prejudice against his book, 'Modern Views of Electricity,' which appears to have been aroused, in some measure, by the idea that electrical investigators of that nationality had been slighted, Prof. O. J. Lodge, the British physicist, is," says the *Western Electrician*, "in danger of running full tilt against the American electricians. In a letter to *Nature*, intended to sooth the wounded pride of the Germans, Prof. Lodge says: 'When I said that the four great names in connection with our partial knowledge of the nature of electricity were (excluding living persons) Franklin, Cavendish, Faraday, and Maxwell, I ought to have interpolated the adjective British before the word "names" in order to avoid entering upon much larger questions than were at all appropriate to the expository course of lectures on which the book "Modern Views" was based.' This will naturally excite the question on this side of the Atlantic: When, pray, did Franklin become a 'British' name? Benjamin Franklin was, of course, a native of Massachusetts, and a devoted American patriot, as well as a distinguished philosopher. It is rather cool, to say the least, to claim him as 'British' at this late day. Prof. Lodge should qualify his list a second time."

Searchlights and Torpedoes.—A dispatch from Newport, dated September 7th, says that the torpedo boat "Cushing" left her dock at the torpedo station the previous evening for practice in searchlight work. There were three objects in view when the boat left the torpedo station. The first was to give the class of seamen gunners at the station practice in keeping the searchlight on rapidly moving objects; second, it was desired to determine at what distance it was possible to distinguish the "Cushing" in her present colour, with the searchlight in its present position, and the boat in its direct rays. The torpedo boat steamed up under the shore and then ran into the full rays of the light, which was pointed directly out through the channel to sea. At a distance of a thousand yards it was light enough to read on board the "Cushing," but she was not discernible from shore by those who had kept their eyes upon her from the time they were within hailing distance. When she disappeared from view rockets were discharged from the station as a signal for those on board the "Cushing" to make plottings of their position. The third object was to determine at what distance, without the aid of the light, the torpedo boat could be located by the noise of her engines, swash of water from her propellers, or other necessary conditions in the running of the ship. There was not a ripple on the waters of the bay, but the bright moonlight was somewhat against the boat. In this test the observers first discerned a few sparks in the vicinity of Rose Island. Then more sparks were seen, and it did not take long to determine that they were from the "Cushing's" funnels. Soon the swash of water was heard; but it was several seconds before, with the aid of the search-light, whose rays were at once turned in the direction where the sparks were seen, the boat herself could be sighted. Plottings were again taken upon signal, and it was found that she was about 800 yards away when first sighted by the electric searchlight.

Earth Charging by Leaky High-Pressure Mains.—On January 8th last a grey mare was killed at Bournemouth by an electric shock. A full report of how this mishap came about was sent in to the Board of Trade by Major Cardew, and published on p. 412 of our issue of February 16th. Briefly this is what happened. A defect existed in the insulation of one of the high-pressure service lines of the local Company, from which sparking had taken place, to the enclosing wrought-iron pipe. This pipe was 32ft. long, laid at a depth of about 18in. and terminated at a brick junction box. The ends were thus fairly insulated, while the rest of the pipe was in contact with the earth, which became charged. The accident took place during the progress of a thaw, after a very severe frost. The accident was caused by leakage from the short length of charged pipe, affecting the potential of the surface of the ground to such an extent that between the fore and hind feet of the horse a sufficient difference of potential was established to give rise to the current which proved fatal. In a Paper entitled "On the Difference of Potential that may be Established at the Surface of the Ground immediately above and at various distances from a buried mass of Metal charged from a High Pressure Electric Light Supply," recently presented to the Royal Society by Major Cardew, R.E., and Major Bagnold, R.E., it is remarked that "the fact of such a result following from a simple contact with ordinary road material was a new experience of the possible dangers attending the commercial supply of electrical energy, and that it was thought desirable to repeat the conditions as nearly as possible, and measure the results obtained. Experiments were accordingly carried out at Chatham on January 26th, March 16th, and May 22nd. A length of 33ft. 3in. of 2in. iron pipe was buried to a depth of 18in. A piece of well-insulated 37/16 cable was inserted in this pipe so that the ends of the conductors made good contact with the inside of the pipe at its centre point. Over the centre of the pipe two 56lb. weights were placed on the surface of the ground, and at a distance of 4ft. laterally another pair of 56lb. weights were similarly placed. A 16-kilowatt alternator was connected by means of an underground cable laid in stoneware pipes to the piece of cable in the 2in. pipe. The other pole of the alternator was connected efficiently to earth at a distance of 140ft. from the piece of buried pipe. An 800-volt Thomson static voltmeter was connected across the terminals of the alternator, and a pair of leads, well insulated, were attached by means of screws to the two pairs of weights situated over the buried pipe. These leads were run back together to the experiment room, and were connected alternately to a 140-volt static voltmeter and a Cardew voltmeter. The voltage of the alternator was varied by means of the exciting current. With regard to the experiment of March 16th, the following note was made: "The soil in which the pipe was buried was loamy, and when digging the trench no worms were noticed; but towards the conclusion of the experiment it was observed that hundreds of worms came to the surface between 3ft. and 9ft. on either side of the pipe; no worms appeared, however, immediately over the pipe." On May 22nd the authors of the Paper observe: "The disturbance of the worms was again very distinct, and they appeared, on reaching the surface, to set their bodies parallel to the pipe, or along an equi-potential line." The alternator never gave more than about 600 volts. The authors conclude: "The experiments, as a whole, show conclusively that, under very different conditions of weather and amount of moisture in the soil, it is possible to produce a fall of potential amounting to 25 per cent. of the whole pressure in the supply between points on the surface of the ground 4ft. apart, a distance which most horses stand over, and, further, that, although the connection of such points by a conducting body naturally reduces this potential difference, yet, when this conductor has about the resistance of a horse (say 400 ohms), sufficient current will pass to give a severe shock. It is hoped that, when opportunity serves, these experiments may be extended to the case of pipes buried to greater depths, and to observe whether any difference is produced by the use of a steady, in place of an alternating pressure."

THE CHEMICAL THEORY OF ACCUMULATORS.—II.

BY E. J. WADE.

Electrical energy does not exist as such in any galvanic cell, whether primary or secondary, but can only be absorbed or given out through the agency of corresponding chemical changes taking place in the cell itself, and its whole electrical behaviour as regards E.M.F., resistance, capacity, and so on, could be predicted and explained were the nature of these changes exactly known. During the last twelve years a great deal of work has been done on lead storage cells in this direction, and many valuable facts have been ascertained; yet at the present day very little is decisively settled as regards the precise chemical reactions that occur, and, consequently, many important characteristics, both good and otherwise, still remain to be satisfactorily accounted for. Probably many consider that time devoted to the elucidation of obscure chemical problems might be utilised to far greater advantage in attempting to construct better and more practical cells, and they are quite indifferent to questions of normal and basic sulphates, sub-oxides, peroxides, and so forth; but this is a mistake. It is true that in very few cases have the chemical theorists pointed the way to any improvements not already embodied in the best practice of the time, but rather have had to formulate their theories so as to account for electrical facts already ascertained; but probably it is for this very reason that storage cells are still so far from practical perfection, and have progressed so slowly as compared with dynamo-electric machinery and other apparatus in whose development theory and practice have gone hand in hand. A good deal has been said at one time and another about storage battery engineers and manufacturers not being chemists; but neither have the chemists who have gone into the subject been electrical engineers, and practical experience with storage cells on a large scale affords much information that could not possibly be obtained from laboratory experiments alone. In justice to the chemists, however, it must be remembered that the problems they have to face, even on their own ground, are by no means easy. Dr. Frankland called attention to this in some remarks he made during the discussion on the Paper by Prof. Ayrton and others on "The Chemistry of Secondary Cells," read before the Institution of Electrical Engineers in 1890.*

"The physical qualities of the cell are capable of very accurate estimation and investigation. But when you come to attempt to ascertain the chemical changes that occur in the charging and discharging of a storage cell you encounter formidable difficulties. The outsider has no idea of these difficulties. Nothing seems more simple than to determine the chemical changes that take place in either the negative or the positive plate of a storage battery. It is not so in reality. The substances used as active materials are, in the first place, mixtures, and the materials obtained at the end of the reaction are also mixtures; and these mixtures are insoluble in any re-agent which does not decompose them. They cannot be volatilised, they cannot be subjected to any process of solution and crystallisation in order to separate and purify their constituents."

Haphazard experimenting on accumulators, however careful and painstaking, seems to have done all that it can do for them, and it now awaits for theory to point out more clearly the causes of the imperfections that still exist, and to indicate the conditions necessary for their elimination; or, at the worst, to show that the limits of advance in any given direction have already been practically attained.

Before attempting to decide what are the actual chemical reactions taking place in a lead storage cell, it will be as well to first see what theories have already been advanced, and how they have been evolved. Planté did not pretend to go at all deeply into the chemical causes of the physical effects that he obtained. He observed the formation of lead peroxide at the positive electrode, and that the local action set up between it and the metallic lead in immediate contact resulted in the formation of lead sulphate, and, as he thought, the liberation of oxygen, but later research has shown that this is due to other causes. He also noticed the reduction of the peroxide to monoxide or litharge at the positive electrode; the oxidation of the lead at the negative electrode and the formation of films of sulphate on both; but on the whole he seems to have been inclined to ascribe the activity of the cell chiefly to occluded oxygen and hydrogen. During the period immediately following Faure's introduction of plates pasted with oxides, this view seems to have been held almost exclusively. Water, it was argued, was the real electrolyte, sulphuric acid merely being added to increase its conductivity, and on charging was decomposed into its constituent gases, which were liberated and absorbed at their respective electrodes. It was, of course, known that the first action of the oxygen was to convert all the active material at the positive electrode into peroxide, but this oxide itself was supposed to take up more gas by occlusion. The well-known property possessed by palladium, platinum, and in a lesser degree by a few other metals, of absorbing oxygen and hydrogen, especially when in a spongy or porous state; Grove's gas battery; Siemens' experiments on gas batteries built up of carbon plates saturated with salts of lead, these were the chief facts on which the theory was based, and the large capacity of a Faure cell was ascribed to the enormous surface offered by the porous mass of reduced oxides.

On discharging the cell the occluded gases recombined to form water, but it was soon perceived that the active material at the electrodes underwent some change as well, and it was thought probable that metallic lead was oxidised to monoxide at the negative, and peroxide reduced to the same substance at the positive

$$PbO^2 + H^2O + Pb = PbO + H^2O + PbO.$$

Dr. O. Lodge, in an able series of articles entitled "Electric Accumulators or Secondary Batteries," which commenced in the *Engineer* in May, 1882,* propounded what appears to have been the most advanced theory held up to that time. He still assumed that water was the essential electrolyte, and that the activity of the negative electrode was solely due to occluded hydrogen, and of the positive electrode during the earlier stages of discharge to occluded oxygen. The reduction of peroxide to monoxide is, however, recognised as an essential reaction, and its subsequent secondary reaction with sulphuric acid to partially form lead sulphate is also noted. A number of interesting experiments are described on the formation of "scums" or films of non-conducting sulphate at the negative plate, but this, as well as its oxidation, are supposed to only occur as its hydrogen becomes exhausted, taking the form of a crust of non-conducting materials that first appears at the surface in free contact with the liquid, and gradually increases in thickness as it spreads inwards. In fact, the formation of sulphate under any circumstances is regarded as an unmitigated evil, so much so that it is expressly stated that the presence of an excess of acid in the cell must be avoided as conducing to the too easy production of this compound at both electrodes.

Almost contemporaneously with Dr. Lodge's articles, some others by Messrs. Gladstone and Tribe, dealing only with the chemistry of the cells, appeared in the columns of *Nature*,† and these, afterwards collected and published in book form,‡ contained the first data obtained by actual analyses, and still constitute the most important contribution to the subject that has yet been made; for, with some comparatively unimportant exceptions, and as far as they go, their conclusions remain equally valid at the present date. They assumed that sulphuric acid, and not water, is the electrolyte, and showed by chemical analyses of exhausted plates that lead sulphate, formed by direct combination with "sulphion" (SO^4), is the normal and only product during discharge at the negative electrode, and they demonstrated that only the merest traces of the hydrogen liberated while charging are absorbed in the reduced material. Their analyses of the positive electrode proved that the peroxide was also converted into lead sulphate, most probably in two stages. In the first place, the hydrogen of the acid would reduce it to monoxide with the formation of water.

$$PbO^2 + H^2SO^4 + Pb = PbO + H^2O + PbSO^4.$$

* *Journal* Inst. Elec. Engineers, Vol. XIX., page 699.

† *Nature*, January 5, 1882, and *seq.*

‡ "The Chemistry of Secondary Batteries." (1883).

Digitized by Google

Then this monoxide would re-act with the sulphuric acid with the formation of lead sulphate and another molecule of water.

$$PbO + H^2SO^4 = PbSO^4 + H^2O.$$

The ultimate result would, therefore, be the formation of a molecule of lead sulphate at each electrode at the expense of two molecules of sulphuric acid, which would be replaced by two molecules of water.

$$PbO^2 + 2H^2SO^4 + Pb = PbSO^4 + 2H^2O + PbSO^4.$$

In addition to this it was shown that the local action between the peroxide and the metallic support was of exactly the same nature, and might be expressed by the same equation, both being converted into lead sulphate.

This new theory gave rise to considerable controversy at the time between Messrs. Gladstone and Tribe and Dr. Lodge, and very well illustrate the different points of view from which a chemist and physicist may regard the same phenomena.

To the latter it naturally seemed highly improbable that any explanation of the cell's action, which involved the production of large quantities of non-conducting insoluble lead sulphate could be correct, however strong the evidence by which it was supported. Lord Kelvin and Dr. Lodge had both failed in their attempts to reduce pure lead sulphate by electrolysis, with platinum electrodes in dilute sulphuric acid, although it peroxidised fairly easily; and even the best of Messrs. Gladstone and Tribe's own experiments showed that this reduction only took place after the action of the current had been prolonged for some days and then not completely. How, then, was it possible for the same result to be obtained in a cell in a few hours, and with a complete absorption of the current until only a very small percentage of sulphate still remained to be acted upon? Messrs. Gladstone and Tribe, although they had undoubtedly proved their case, do not seem to have recognised that in putting the chemistry of the cell on a better basis they had rendered its physics proportionately difficult to understand. Later experience has shown that the conception of the distribution of the sulphate formed was largely at fault. Instead of the portion of the active material first acted upon being wholly converted into sulphate, and producing a solid crust at the surface in free contact with the liquid, the action takes place, more or less uniformly, throughout the whole mass, owing to its extreme porosity, and leaves a nucleus of conductive material underneath, by which the current in charging is distributed to every portion of the plate. Mr. Swinburne and others have also shown that lead sulphate, when mixed with litharge, reduces easily enough, so no doubt it is very largely a matter of conductivity; but this is not a complete solution of the difficulty, and a perfectly satisfactory explanation has never yet been propounded.

Early in 1883* Dr. Frankland also showed that lead sulphate was the ultimate product at both electrodes, although he expressed his equations in terms of hexabasic sulphuric acid ($H^2SO^4 + 2\ H^2O$ or SH^6O^6), which he considers to be the real electrolyte. He demonstrated that neither oxygen nor hydrogen is occluded in the fully-charged plates, and drew attention to the fact that the changes in the specific gravity of the acid afforded a means of determining the amount of sulphate formed, and might be utilised in practice to indicate the degree to which a cell was discharged.

From this time onwards the double sulphating theory rapidly gained ground, although even in 1886 the late Mr. A. Reckenzaun, who was exceptionally well acquainted with all matters pertaining to storage cells, seems to have still adhered to the occluded gases theory. It is now almost universally accepted as representing the final results of discharge; but considerable differences of opinion still exist, especially with regard to the positive electrode, as to how far it is a primary electrolytic action which contributes towards the E.M.F. of the cell, and how far a secondary local reaction which is dissipated in the form of heat. The chief practical outcome was a recognition of the necessity for supplying cells with stronger acid and more of it, so that the normal sulphating could easily take place without the electrolyte becoming too weak.

The corrosion or rotting of the positive grids and plates, by reason of local action with the lead peroxide, seems to have

* *Proc.* Royal Society, Vol. XXXV. (1883), page 67.

been considerably over-estimated by the early manufacturers, and Messrs. Gladstone and Tribe's researches tended in the same direction. The users of cells were warned never to overcharge them, as this was supposed to reduce the skin of lead sulphate that otherwise protected the positive support, and thus promote local action.

Messrs. Drake and Gorham, however, in 1886* showed that the real protective coating was the dense film of peroxide into which the sulphate was gradually converted, and that some overcharging was decidedly beneficial, as it hastened the formation of this film, besides reducing any residue of sulphate that was present elsewhere. On the other hand, they found that the over-discharging then generally practised was the real cause of the excessive sulphating, buckling and local action to which the cells were so liable. These views entirely revolutionised the methods of treatment formerly adopted, and put them on the basis on which they have since remained.

Very few additions were now made to the chemistry of the cells for some little time. The excess of sulphate formed under certain conditions, and the extreme difficulty with which it was again reduced still continued to puzzle investigators, and seemed to point to the existence of two different kinds, one reducible and one not. Various theories of double sulphates, basic sulphates and so on, were developed to meet the occasion, but had very little evidence to support them. In 1889† Dr. Frankland made some experiments which seemed to indicate the existence of two basic sulphates obtainable by the action of sulphuric acid on litharge and minium respectively, but both Messrs. Gladstone and Hibbert‡ and Mr. Robertson§ consider they are only mixtures of normal lead sulphate with more or less oxide.

The Paper by Prof. Ayrton and others on "The Chemistry of Secondary Cells," read before the Institute of Electrical Engineers at the end of 1890,‖ did not propound any new theory of their action, but supplied some very interesting data, both qualitative and quantitative, as to the composition of the plates at various stages of charge and discharge. Their investigations also included an examination of the temperature changes of a cell during charge and discharge, and these, together with some experiments made by Messrs. Duncan and Wiegand about the same time, and communicated to the American Institute of Electrical Engineers in May, 1889,¶ form the first definite contributions to this branch of the subject. In both Papers attention is called to the remarkable fact that a cell actually cools during discharge.

So far, almost all the investigations into the chemistry of the cells had been confined to an examination of the changes taking place at the electrodes, and very little attention had been paid to any reactions occurring in the electrolyte; but the researches of the last three or four years seem to indicate that there really lies the explanation of many obscure points.

Planté had, indeed, observed the formation of some unstable compound containing "active oxygen," which he thought to be hydrogen peroxide (H^2O^2), and he ascribed the high initial E.M.F. of a freshly-charged cell to its presence; but, to suit the needs of the "occluded gas" theory, it was assumed that the real agent was oxygen, liberated at the positive electrode in the form of ozone, and this idea has prevailed more or less generally to the present day.

In 1878 Berthelot discovered the highly-oxidised compound persulphuric acid, and showed that it was a direct product of the electrolysis of dilute sulphuric acid; while hydrogen peroxide, whose presence under similar conditions had long been known, was chiefly a secondary product resulting from its subsequent reversion to normal sulphuric acid.

$$H^2(SO^4)^2 + 2H^2O = H^2O^2 + 2H^2SO^4.$$

In 1883** Messrs. Gladstone and Tribe noticed persulphuric acid in some solution that had been subjected to electrolysis;

but Prof. Armstrong and Mr. G. H. Robertson, in 1891,* were the first to call attention to the probability of this compound being the cause of the variations of E.M.F. and other phenomena observed in the cells, and the latter gentleman discussed the matter in more detail in a Paper read before the Society of Arts in the same year.† He showed that persulphuric acid and hydrogen peroxide were formed in considerable quantities at the positive electrodes of a cell during charging, their relative proportions depending on the strength of acid that was used; and, further, that the latter compound was capable of causing local action and ultimate sulphating at both electrodes. He also considered that a cell's E.M.F. was in some way dependent on the amount of these compounds present, but his experiments on this point were not very definite or conclusive.

Meanwhile, Messrs. Gladstone and Hibbert had commenced an investigation of the relations of the electrolyte to the E M.F., from the point of view of the strength of acid. Their first results were communicated to the Physical Society in 1890;‡ but in a very interesting Paper "On the Cause of the Changes of Electromotive Force in Secondary Batteries," read before the Institute of Electrical Engineers in 1892,§ they go much more fully into the matter. Messrs. Duncan and Wiegand, in their communication referred to above, had already shown that during discharge the strength of the solution contained in the pores of the active material might be very greatly reduced by the abstraction of sulphuric acid to form sulphate with the production of water far faster than it could be equalised by diffusion from the surrounding liquid; and, following up this line of argument, Messrs. Gladstone and Hibbert endeavoured to prove that the loss of capacity and E.M.F. with heavy discharges, and subsequent recovery on standing; the high E.M.F. observed immediately on the cessation of charging; and the normal variations of E.M.F. during charge and discharge would all be accounted for in a similar way. Although in some points, perhaps, the deductions drawn from their experiments are stretched to cover rather more than can be explained by their aid alone; yet, on the whole, they supply a thoroughly well-connected chain of evidence and reasoning, from whose main conclusions it seems difficult to dissent. During the discussion that followed their Paper, Mr. Robertson advanced some further arguments in favour of the persulphuric in the electrolyte being the real cause of the variations of the E.M.F., and Messrs. Gladstone and Hibbert again returned to the subject from their point of view in a communication to the Physical Society shortly afterwards;‖ but since that time no further direct evidence bearing on the point in dispute has been adduced.

The last contribution to the chemistry of lead storage cells worth noticing is that of M. M. G. Darrieus read before the Société Internationale des Electriciens in May, 1892. The author advances some theories of their action, so widely at variance with those generally accepted and the results obtained by other experiments that they would require a considerable amount of confirmatory evidence to sustain them, especially as the details given regarding the apparatus used, and the methods of electrical measurement employed are very meagre. He is strongly of opinion that the formation of lead sulphate at the positive electrode is purely a secondary reaction, the reduction to litharge being the essential one. Further, in order to account for the high E.M.F. of the cell, he maintains—and it is here that the originality of his views is most apparent—that the porous lead of the negative electrode, prepared by electrolytic reduction, is in a highly energised allotropic condition, something similar to "explosive antimony"; and that consequently it furnishes far more energy and E.M.F. by its conversion into lead sulphate than lead in its normal metallic state. Besides this, he considers that the sulphating takes place in two stages; first an oxidation of lead to sub-oxide (Pb^2O), and then a conversion into lead sulphate with the elimination of water; half the lead, however, returning to the metallic state, and being protected from further action by the surrounding sulphate.

$$Pb^2O + H^2SO^4 = Pb + PbSO^4 + H^2O.$$

Although it may be impossible to agree with the whole of the conclusions drawn by M. Darrieus from his researches, yet at the same time his paper is well worth study both for its originality and suggestiveness, and some of his experiments might well repay repetition. With the exception, however, of a passing allusion to it by Dr. Gladstone, the paper does not appear to have attracted much notice in England.

THE CONSTRUCTION OF RESISTANCES.*

BY D. K. MORRIS

(Continued from page 607.)

While on the subject of coils designed to assume temperature conditions rapidly, it may be of interest to describe a type of coil in which this point is almost the sole object of design, namely, a coil suitable for the determination of specific resistance over wide ranges of temperature. Such coils should be small, have very little mass, and be at all points accessible to the insulating medium in which they are intended to be measured.

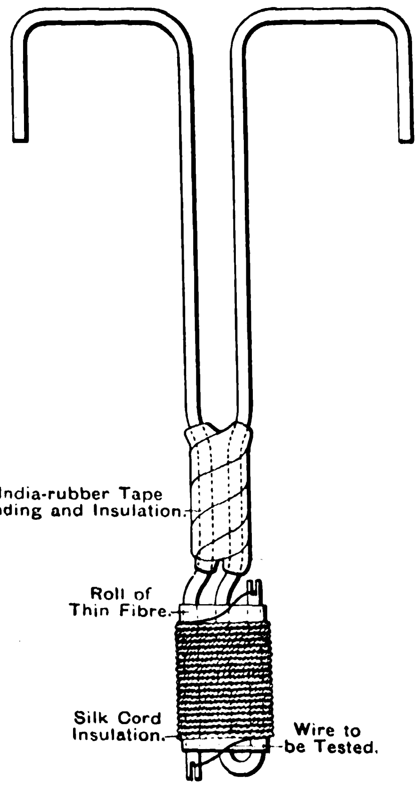

FIG. 6
Coil used for Determination of Specific Resistance at Low Temperatures (Dewar and Fleming). Rather l ss than half actual size.

Measurements of resistance can be easily carried out with a high degree of accuracy; but this refinement of measurement is very apt to be worthless if the substance under test has a large temperature coefficient, for the possible error in the measurement of temperature may correspond to a large error in the resistance.

The coils used in the research previously referred to were constructed as in Fig. 6. Two pieces of stout copper wire were taken and bent thus, and bound together at the middle with insulating tape, and the four ends were tinned. A piece of very thin vulcanised fibre sheet (like thin card) was then fastened to one leg and wound round, a turn and a half, and fixed at the other.

* A Paper read at a Student's Meeting of the Institution of Electrical Engineers, March 16, 1894.)

Digitized by Google

Two lengths of silk cord were wound side by side from top to bottom of the fibre cylinder, one was fastened at both its ends, and, after immersion for some time in melted paraffin wax, the other was unwound, thus leaving a spiral channel into which the wire of known length and cross section could be wound, and its ends soldered to the ends of the copper leads. In this way a length of wire of as much as three metres could be wound in a single open layer.

Such coil had very little mass, and hence assumed the temperature of its surroundings readily. This was especially neces-

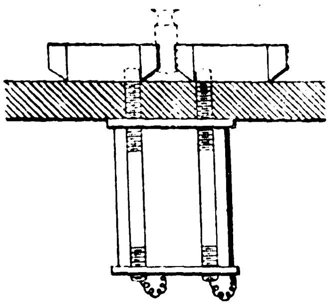

Fig. 7.

sary in the low temperature experiments, for when immersed in, say, liquid oxygen, they did not boil away any very large quantity before they were cooled down.

Resistance Boxes.—The principles which determine the making of a good standard of resistance have been given at some length, because these are the points which should be aimed at, though in a lesser degree, in the construction of ordinary resistance coils. Resistance boxes contain sets of coils which are definite multiples or sub-multiples of the ohm. The arrangement of these coils depends on the purpose for which the box is required.

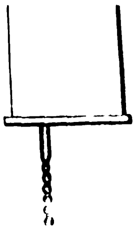

Fig. 8.

Each coil has a separate core, which ought to be a brass or copper cylinder covered with thin rubber or varnished paper, the cheeks being of thin ebonite. When a coil of given resistance is to be wound, a length of well-insulated wire of slightly greater resistance is cut—doubled on itself at its middle point, and wound thus double on its core. This method of winding is important for two reasons: Not only do we in this way avoid induction effects while the current is varying, but we prevent

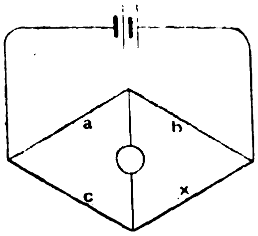

Fig. 9.

the direct magnetic action of the coils which would render any ordinary galvanometer practically useless. After each layer of the coil is wound, it is dipped into melted paraffin, so as to fix the turns relatively to one another, preserve them from damp, and insure better insulation.

When the coil is wound, it is fixed in position by two long brass or copper screws passing through the cheeks and ebonite cover to two brass pieces at the top, which are arranged so that the coil can be short-circuited by the insertion of a brass plug (Fig. 7) which must be accurately fitted.

The ends of the wires are then soldered to these long screws, care being taken to use no corrosive flux (resin being the right thing).

The coil is now brought to the temperature at which it is to be accurate, and is finally adjusted.

There are several ways of adjusting; the simplest is to slide the wire into or out of the drop of melted solder at the point, allowing it to cool completely before re-measuring. Another way is to leave the middle point of the wire, where it is doubled, projecting out of a hole in the cheek; to strip the insulation from this part, and to go on twisting the loop together until the resistance is *very* nearly down to its proper value, and then to touch it with solder (Fig. 8).

The coils of lower resistance are made with thicker wire to render accurate adjustment easier.

The cutting away of the brass blocks underneath, is to increase insulation and to allow the removal of dust which may collect there on the ebonite, as this might seriously diminish, by its shunting action, the effective resistance of a coil of several thousand ohms.

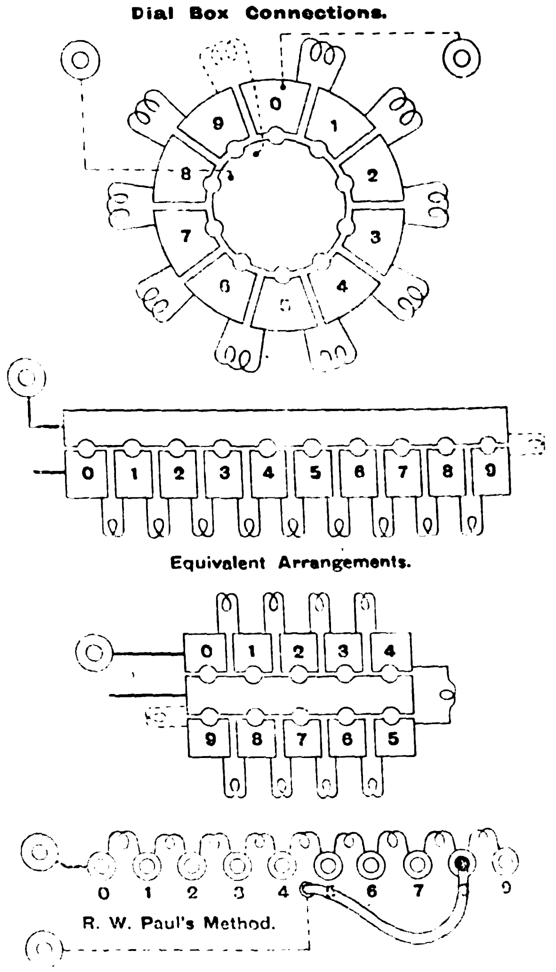

Fig. 10.

For instance, to take a bad case, suppose the insulation resistance to fall to about 10 megohms, while the coil itself was one of 10,000 ohms.

The effective resistance would be $\dfrac{1}{\dfrac{1}{10{,}000}+\dfrac{1}{10{,}000{,}000}}$ $=\dfrac{10{,}000{,}000}{1{,}001}=\dfrac{10{,}000}{1{\cdot}001}$; so an error of 1 in a thousand would arise, which would in many cases be serious.

Arrangement of Coils in a Resistance Box.—The commonest way of measuring an ordinary resistance is to compare it with known ones by the Wheatstone's bridge method, Fig. 9. We all know the diagram of connections—three of the arms must be known, the fourth can then be calculated.

You see from the diagram that these three arms will be wanted all in series, and it is usual to arrange them perma-

Digitized by Google

nently so. And since $\frac{a}{b}=\frac{c}{x}$, therefore $x=\frac{b}{a}c$; so if $\frac{b}{a}$ is made an even power or root of 10, we get x by simply shifting the decimal point of c. Hence the common disposition of coils in Wheatstone's bridge sets. Thus, in the best boxes, the ratio arms each contain 10, 100, 1,000, and 10,000 ohm coils, placed at the back of the box, and the rest of it is occupied by a set of coils, such that we can get any unit between 0 and 20,000 ohms. This is done by providing coils of 1, 2, 2, 5, 10, 10, 20, 50, 100, 100, 200, 500, 1,000, 1,000, 2,000, and 5,000 ohms.

An excellent arrangement of coils for a series resistance box is that used in dial boxes, Fig. 10. They contain three, four, and sometimes more sets of 10 equal resistance coils, 10 units, 10 tens, 10 hundreds, and so on. The connections are as shown on the diagram.

It is obvious that only one plug for each digit in the result is needed, and that the number at the position of the plug represents the number of ohms (or tens of ohms, or whatever

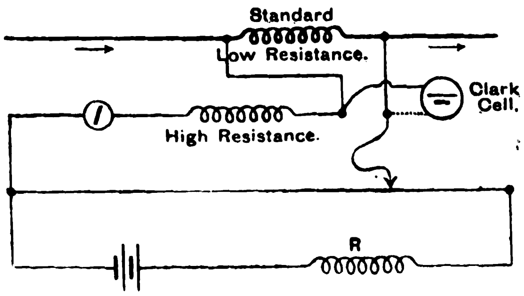

Fig. 11.

it may be) in circuit due to that part of the box. So that one reads such a dial box exactly in the way that one reads a gas meter or a speed counter, arranging the decimal point according to the ratio coils in use.

Two equivalent arrangements are shown below on the diagram, and a modification in the arrangement by R. W. Paul, in which a flexible cord is used, and the plugs can be inserted into complete sockets, which, therefore, cannot get out of shape owing to warping of the cover.

Resistance boxes of the Post-Office pattern have the battery and galvanometer keys permanently connected up; while "testing sets" usually contain the galvanometer in the box, the only terminals supplied being one pair for the battery and one pair for the resistance to be measured.

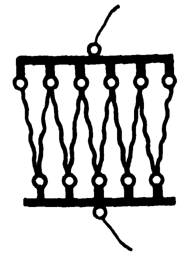

Fig. 12.

Conductivity boxes, or boxes in which the coils are arranged in parallel, are sometimes used, though comparatively rarely. The conductance of the circuit is obtained by adding the conductances of the coils.

Very high resistances are sometimes made of a strip of graphite in an ebonite case; but this method of construction is of little use in accurate work.

We now come to the consideration of accurate resistances designed to carry considerable currents. Such resistances are necessary for making measurements by the potentiometer or Poggendorff's bridge method. This method, which has been brought into practical use quite lately, is one of the best methods of measuring large currents and small resistances (Fig. 11). We have a wire, down which there is a uniform fall of potential of two or three volts, kept up by a couple of small accumulators, and after adjusting R so that on calibrating by a Clark cell there is a fall of exactly one volt per metre of the slide wire, we can read small differences of potential with considerable accuracy by finding how many centimetres of the wire will neutralise the unknown E.M.F., as indicated by the zero galvanometer.

Thus, to measure a small resistance, we pass a considerable current through both the known and the unknown resistance, and compare the fall of potential down each, which gives the ratios of resistance. While, to measure a large current, we simply pass it through a known resistance capable of carrying it, and measure the drop.

If, as would usually be the case in setting up a potentiometer, apparatus is not at hand to measure the low resistance as it stands accurately, the best way of proceeding is as follows:—

Let the required resistance be $\frac{1}{100}$th of an ohm. Take ten German silver wires, each having accurately the *same* resistance and about $\frac{1}{10}$th of an ohm. Join them in a zigzag way between two rows of mercury cups (Fig. 12), and measure them on a Wheatstone's bridge thus in series, when they will be about one ohm.

Their resistance, when joined in parallel by stout copper connections, will be accurately $\frac{1}{100}$th of the value in series. If, however, one is able to measure low resistances accurately, then it is more convenient to solder all the wires side by side to two massive end pieces to which are attached terminals.

Messrs. Crompton's form of low resistance for this kind of work is made in a different way. The following is a description of a $\frac{1}{100}$th of an ohm resistance made by that firm.

A wide strip of manganin, 6¼in. wide, 20in. long, and $\frac{1}{16}$in. thick is divided into four by three slots $\frac{1}{10}$in. wide (Fig. 13). Stout terminals are fixed to the ends; two blocks of ebonite are fastened on it near these two terminals; and screws, passing through the manganin and the ebonite blocks up to two small terminals, serve as connections for the potential wires. The resistance is measured between these two screws, which should not be placed too near the large terminals.

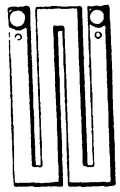

Fig. 13.

If it is desired to measure 100 volts (continuous) with accuracy, a resistance is required which will stand that pressure without any appreciable heating, and which is divided exactly in the ratio of 1 : 99; so that if, by the potentiometer, we measure the fall of pressure down the section, which is $\frac{1}{100}$th of the total, and multiply by 100, we get the total pressure.

To do this conveniently, two horizontal bars of ebonite about a foot long, and as much apart, each having a hundred deep notches, are supported in a wooden frame. Then 200ft. of fine platinoid wire (No. 38) is wound up and down till the notches are full.

The resistance of the whole will be about 1,400 ohms, and that of the first turn can then be accurately adjusted to be $\frac{1}{100}$th part of this. The measurement of 100 volts by the potentiometer then becomes quite easy.

(*To be concluded.*)

THE MANUFACTURE OF ALKALI AND BLEACH BY ELECTROLYSIS.

The latest attempt of importance to manufacture caustic soda and chlorine by means of electrolysis is that which is being made by the Aluminium Company, under the guidance of Mr. H. Y. Castner. From such statements as have been published it appears that the process belongs to the type in which mercury is used, both as a cathode and as a means of transferring sodium from the decomposing cell to a compartment in which the sodium amalgam is acted upon by water with the formation of caustic soda. In this instance the mercury forms the bottom layer in a cell divided into three com-

Digitized by Google

partments, the middle member of which contains an iron cathode immersed in caustic soda solution, while the remaining pair are provided with carbon electrodes dipping in brine. The mercury at the bottom of the composite cell serves as the cathode of the two outer compartments and as the anode of the middle compartment, receiving sodium in the former and giving it up in the latter. Bodily transmission of the mercury charged with sodium from the outer to the middle compartment is effected by communicating a rocking motion to the whole apparatus. It is claimed that by this arrangement the usual difficulty arising from the need of a suitable diaphragm of low resistance is overcome, and that the voltage required is correspondingly small as the electrodes are brought almost into contact with each other. It is evident that the fact that sodium is obtained as an intermediate product is not a cause of any increase in the voltage necessary for each cell, as the sodium does not appear as an end-product of the reaction, but generates in the cathode compartment the same voltage as that which its liberation absorbs in the anode compartment. The critical voltage of the cell is, therefore, that proper to the electrolysis of a solution of sodium chloride. Any extra voltage that may be required in practice is due to the internal resistance of the electrolytic cell

The apparatus, which is said to have been in regular use at Oldbury for about six weeks, consists of 30 cells 6ft. in length, 3ft. in width, and 6in. in depth, jointly capable of an output of 1,200lb. of caustic soda and 1,000lb. of chlorine per day of 24 hours, with an expenditure of 110 I.H.P.; each cell, therefore, yielding 38½lb. of caustic soda and 34½lb. of chlorine per 24 hours, and absorbing about 3½ I.H.P. The caustic soda is obtained as a 20 per cent. solution (presumably fairly free from salt) from the cathode compartment, and when evaporated yields solid caustic soda, containing as much as 99 per cent. NaOH. The chlorine is of a purity of 95-97 per cent., the balance being alleged to be hydrogen, doubtless derived from the premature action of the sodium dissolved in mercury in the anode compartment upon the brine with which it is in contact. The simultaneous presence of free chlorine and hydrogen is only possible while the conditions necessary for inducing their combination to form HCl (*e.g.*, exposure to strong light) are not operative. Should such conditions obtain, loss of chlorine will, of course, occur, with a corresponding deterioration of the bleaching powder ultimately produced. The remaining hydrogen appears in the cathode compartment, but its utilisation does not appear to have been attempted. An electrical efficiency of 88·9 per cent. is claimed for the process.

It is with this last statement that we are more particularly concerned, as it is one of those illusory allegations which are especially mischievous, tending to injure legitimate electrolytic enterprise. Adopting the moderate estimate that 3½ I.H.P. per tank corresponds with 2,100 watts at the electrodes, and taking the figures given above—viz., that the resulting production of chlorine is 34½lb. per 24 hours—it follows that the voltage for each cell is 4·3 volts. Seeing that the critical voltage for the decomposition of sodium chloride in aqueous solution is a trifle over two volts, it is obvious that an efficiency of barely 50 per cent. is obtained, instead of the 88·9 per cent. which is claimed. In short, the process in this respect is neither better nor worse than a dozen others which have been brought forward within the last few years. In all cases a voltage of 4·5 to 5 volts is necessary when everything is working smoothly, and a good deal more becomes requisite when the apparatus is not quite at its best. It must not be supposed that this huge waste is inevitably fatal to a process; but it is futile to ignore its existence, and claim an efficiency contradicted by the very figures put forward by the inventor himself. In this particular case the cost of energy necessary to produce one ton of caustic soda and about 2½ tons of chloride of lime would be approximately £4.2, assuming that a large plant was employed and the process worked continuously. Any estimate of this kind only touches the fringe of the matter, however, as the cost of the plant and its up-keep are apt to be heavy in all electrolytic processes. Thus it comes about that in spite of the enormous apparent saving which the adoption of electrolysis would effect in the manufacture of alkali and bleach, the civilised world is still dependent on purely chemical processes for the supply of these commodities. A good deal of progress has been made, and, on the whole, on sound lines; but electrolytic soda and bleach will not have the market to themselves yet awhile. The time when they shall have driven out their rivals will not be hastened by overstating the advantages of processes for their manufacture.

THE CLARET-WUILLEMIER SYSTEM OF ELECTRIC TRACTION.

For some months past an electric tramway on a system possessing some curious features has been working without a hitch at Lyons in connection with the Exhibition now being held there. The line is double track, one-metre gauge, some two miles long, and it runs from the centre of the town to the Exhibition gates. The generating plant is inside the Exhibition grounds, and comprises a 100-H.P. gas-engine, belted to a six-pole 500 volt Thury dynamo; the gas is manufactured on the spot by the Buire-Lancauchez process. The rolling stock comprises 12 motor-cars, each weighing, with its complement of 42 passengers, and its 20-H.P. double-reduction Thury motor, something like nine tons. The speed is regulated by switching resistances into and out of circuit. Carbon brushes are used, the wear of which, it is said, amounts to 0·06 mm. per run of

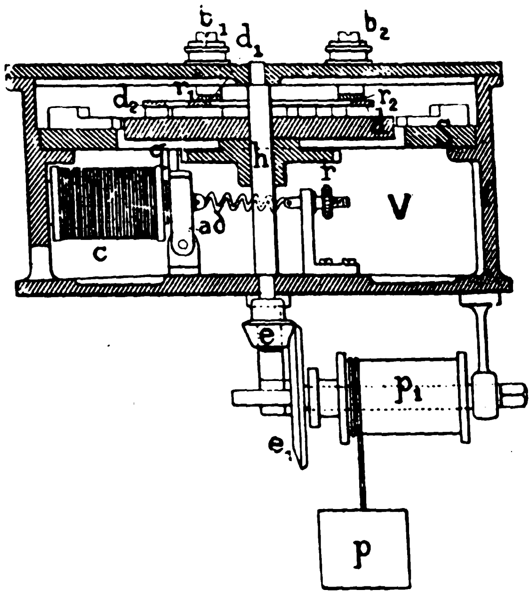

FIG. 1.—Distributor. Elevation.

100 kilometres. During the month of August the line was used by 124,000 passengers; 15,000 being the largest number carried as yet in one day.

The Claret-Wuillemier system is simply a special application of the principle of bringing successively into contact with the "live" conductor sections of an insulated conductor laid between the rails on a level with the roadway, a principle which was first thought out by Profs. Ayrton and Perry, and which met with what was, perhaps, its most practical exposition in the Lineff device (see *The Electrician*, Vol. XXV., p. 205). Compared with the simplicity of Mr. Lineff's plan, that of MM. Claret and Wuillemier appears complicated to a degree; but since it has managed to withstand the test of actual running, it must be easier to make it work well than to describe it clearly.

The sectional conductor consists of reversed rails 2·8 metres long and 3 metres apart; so that the cars, which are 7·6 metres long, almost cover two sections and an intervening gap. The sections are insulated by wood-paving blocks run in bitumen. The main cable, which has a section area of 0·135 sq. in., and is armoured and lead-covered, is run under the pavement, the feeding wires from the distributors being led to the sectional conductor inside a wooden trough impregnated with a preservative and tarred. The return is by the rails.

The distributors, which are laid in pits 100 metres apart, are as follows: In each distributor there is a spindle *h* (*see*

Digitized by Google

Fig. 1) carrying a ratchet wheel, r, upon which rests an insulating base, d, which supports two copper rings, d_1 and d_2, insulated from each other. Ring d_1 carries the horizontal arm m_1 (Fig. 2) and ring d_2 the arm m_2; so that as h revolves these two arms come into contact with the contact-pieces t_1, t_2, &c. The arm m_1 is somewhat wider than the interval between two contact pieces, m_2 being narrower than this interval. In Figs. 3 and 4 we see that the arm m_2 presses on the upper edge of the contact pieces, whilst m_1 presses only on the lower part. Each contact piece is, however, all in one part, except in one instance, where the two portions are insulated from each other, as shown in Fig. 4. From each of the contact pieces

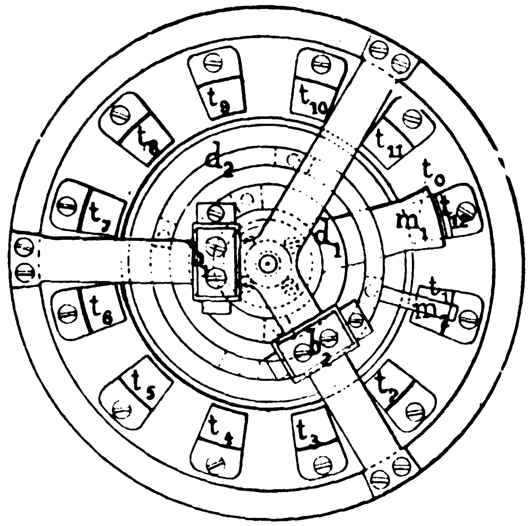

Fig. 2.—Distributor. Plan.

wires run to the corresponding sectional conductor. The rings d_1 and d_2 are placed in connection with the terminals b_1 and b_2 respectively (Fig. 1) by means of brushes, b_1 being in connection with the main conductor, and b_2 with one end of the coil of the electro-magnet c (Fig. 1), the other end of which is to earth. The rotation of the arms m_1 and m_2 is effected by means of a weight (or electric motor) p, which communicates motion by the bevel wheels e and e_1 (Fig. 1) to the spindle h, the ratchet wheel r of which cannot rotate, however, until a stud, q, on the armature of the electro-magnet c releases it.

By aid of the diagrammatic sketch (Fig. 5) we may now possibly be able to see what happens as a given car, X, passes along. As shown, the rear collector y_1 of the car is just leaving the sectional conductor s_1, and the front brush y_2 has just come into contact with the section s_2. The current from the dynamo reaches the distributor by the terminal b_1, passes to the copper ring d_1, along the arm m_1 to the contact-piece t_1, thence to the

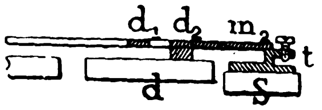

Fig. 3.—Details of Distributor.

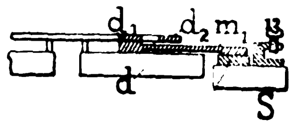

Fig. 4.—Details of Distributor.

sectional conductor s_1, along the collector y_1, to the car-motor, and thence by the wheels to the rails x and back to the dynamo. But a portion of the current finds its way back *viâ* collector y_2, sectional rail s_2, contact piece t_2, arm m_2, ring d_2, terminal b_2, and electro-magnet c. This current causes the electro-magnet to attract its armature and to release the ratchet-wheel r, so that the weight immediately p comes into action, and revolves by the ratchet-wheel amount of one tooth, switching m_1 on to t_2 and m_2 on to t_3, when the whole of the motor current is collected by y_2; and the electro-magnet, being cut out of circuit until y_2 comes into contact with s_3, ceases to attract its armature and allows the stop q to arrest the motion of the ratchet-wheel r, and so on, until the car has passed to the last sectional rail connected to the particular distributor. To this last section is also joined up the first contact-piece of the next distributor, which is thus enabled to take up the running.

On looking at Fig. 4 it will be observed that the lower part of the last contact-piece, on which presses the arm m_1 conveying the main current, is insulated from the rest, so that when the car leaves the last sectional rail connected to the distributor under consideration, it leaves the distributor insulated, and the car has to take all its current from the next distributor, and, no current finding its way home *viâ* the electro-magnet c, the distributor remains at rest until the front collectors of the next car comes on to sectional conductor s_1 when the cycle of operations begins once more.

A distributor of this kind, it is obvious, is only applicable to a double-track line; that is, to one on which the cars are always travelling in the same direction along the same individual track. It will also be obvious that the use of distributors results in a perfect block-system, the cars being perforce kept apart by at least the length of the portion of the sectional conductor served by one distributor. To apply the distributor to a single-track line, with cars running in either direction, several addi-

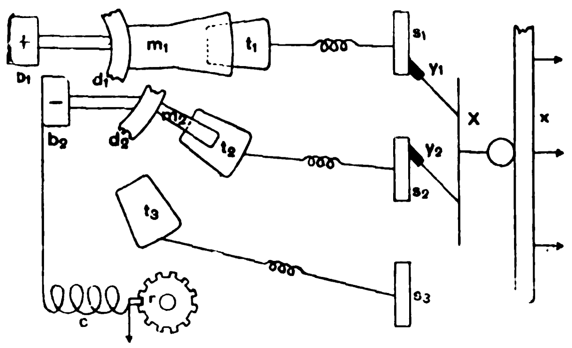

Fig. 5.—Diagram of Connections.

tional complications are needed, for a detailed description of which we must refer our readers to *l'Electricien* for September 22nd, whence these particulars and some of the illustrations are taken.

In Fig. 6 we have a side view of the collectors used at Lyons, each of which is composed of three pairs of shoes, each car having four sets altogether, two being at the rear and two at the front of the car. The part a is a permanent magnet, ff being cast-iron pole-shoes capable of revolving round x, rr

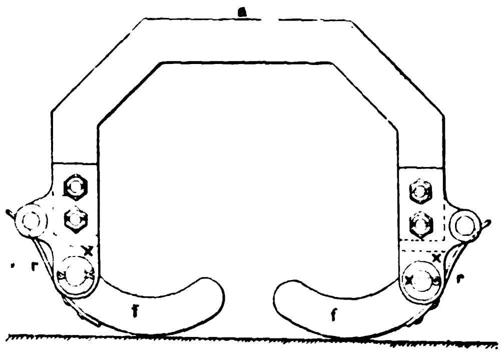

Fig. 6.—Collecting Shoe.

being springs which lift the collecting-shoes off the roadway when they are not pulled down by the attraction of the iron sectional conductor.

The Claret-Wuillemier system is certainly ingenious, and has, it would seem, been successful in practice; but particulars as to first cost and maintenance would be of interest.

Society of Engineers.—Mr. Perry F. Nursey has been unanimously elected honorary secretary and treasurer of this society. The next ordinary meeting of this society will be held at the Town Hall, Westminster, on Monday, October 1st, when a Paper will be read on "The Utilisation of Town Refuse for Generating Steam," by Mr. T. W. Baker, B.A. The annual dinner will be held at the Holborn Restaurant, on Wednesday, December 12th.

STEEL-PLATE PORTRAITS

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; and Dr. Heinrich Hertz, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar of Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

PHOTOMETRIC UNITS AND DIMENSIONS.

The introduction and progress of electric lighting has conduced to the development of photometry, and while the methods and apparatus which are now used differ but little from those which were employed fifteen or twenty years ago, the immature and defective state of the science of photometry as a section of optics has been forced upon the notice of all those who have treated the subject in a scientific manner. The mere comparison of the candle-power of two sources of light of similar colour, a process which is the beginning and the end of the science of photometry to many people who imagine they know all there is to know about the matter, is really a very limited branch of the science. Photometry received much more attention at the end of the last and the beginning of the present century from Continental physicists than from our own, and the names of LAMBERT, BUNSEN, BOUGER, FOUCAULT, WEBER, are familiar in connection with this subject. It is hardly the fault of English physicists, then, that the vocabulary, definitions, and units of photometrical quantities should be in such a state of confusion. Just as in the early days of electrical science the crude hypothesis of electric fluids led to the use of the word "current," and thus wrought immediate and irremediable mischief; so, by some accident, the notion of a flux of light was not clearly recognised, where a real flux exists. To meddle with the nomenclature of photometry is a serious matter, for since the boundary between "electro-magnetics" and optics has disappeared, the geometrical principles of photometry cannot be distinguished from those of radiant energy.

It is well, for several reasons, that a Frenchman has undertaken this task. MASCART, CORNU, PALAZ, VIOLLE, HOSPITALIER, and BLONDEL are among the modern writers on photometry, who have not failed to take advantage of the flexibility of the French language, and its ample vocabulary. But the task of translating M. BLONDEL's article on photometric magnitudes and units, which will be found in our present issue, was no easy one. We have freely quoted the original French,

Digitized by Google

since it is not only the meaning which we have to give, but the actual words chosen by the author. For these words we have endeavoured to find close English equivalents. The need for reform is well established by M. Blondel; the incoherent jumble of geometry with photometry, and the illogical suppression of the idea of a flux of light in all directions is clearly pointed out. While we regard this as a most important contribution to physical nomenclature, we must confess that the author goes rather far with his system, sound as it is. But there is no harm in this. On the contrary, it is the meagreness of the phraseology of the past that has led to confusion, and if M. Blondel offers us more than we feel inclined to use, we have but to adopt that which best claims our attention and supplies our wants. The recognition and acceptance of the units and their definitions is the first step; and the naming of them, where naming is necessary, may be left for the present. We are, indeed, inclined to think that the adoption of symbols for these units is of greater importance than the settling of names. We have got on very well with the idea of magnetic induction and the symbol **B**, and the expression "lines" when a numerical magnitude was given, without the name "gauss" or "thom"; it is the minority who clamour for such names. Fortunately, the whole of these photometrical units are based on the fundamental one of luminous intensity, which is practically 1 c.p. It seems highly probable that in this country and in America the "candle-power" will remain, while its magnitude may perhaps be adjusted by a congress or by the Board of Trade. The unit of luminous flux may, perhaps, deserve a name; but it cannot be a "candle." The idea that a light of one candle-power gives the light of 4π, or 12·57 "candles," though technically true, would be too absurd. This flux is often spoken of as "total light" or "quantity of light." This is not quite accurate. We really mean, as it were, a current of light or rate of emission of luminous radiant energy. The product of this by unit time would give a true quantity, Mr. Blondel's last unit is of this kind; but it is not likely to be often required. It is under certain circumstances necessary to employ the notion of a flux of light; and it is wrong to describe the unit as 4π candle-power; hence the need for a name. If some name is not adopted, enterprising lamp makers will advertise lamps of 201 candles, meaning 16 candle-power. The third unit, that of illumination, really needs a name. M. Hospitalier and others have strongly objected to the bougie-metre and to the candle-foot; and, with some sophistry, it has been argued in defence that, although there may be a little ambiguity in speaking of "7·5 candle-feet," there is nothing unsound in "7·5 times a candle-foot." It is a que tion whether M. Blondel's illumination, intrinsic brilliancy, and intrinsic radiation might not be reduced to a single unit. It will be seen that their dimensions are identical. There is a very simple connection between them, and a little examination will show that the same unit will do for each. Suppose a light of k candle-power has an effective luminous area of a square feet. If the light be an opaque incandescent sphere of 1 foot radius it will show in any given direction a projected area of π square feet, or the same as a disc of 1 foot radius. Its brightness or intrinsic brilliancy is its candle-power per unit area, or k/π candle-power per square foot. The total quantity of light, or luminous flux, emitted by the sphere is $4\pi k$ units, and the illumination it can produce at a distance of f feet (this distance being not less than 8 or 10ft.), is k/f^2 candle-feet. If it be desired, then, to know the quantity of light given out per unit area of a luminous body, this is at once obtained from the brightness, by multiplying by π. Now, the total flux of light emitted by the sphere is $4\pi \times k$ units, the total area of luminous surface is $4\pi \times 1^2$ square feet, hence the intrinsic radiation, which might, with some reason, be called the illumination of the luminous surface, is $(4\pi \times k) / (4\pi \times 1^2) = 1$ candle-foot, where $k = 1$. This, as we have already shown, is π times the brightness, a relation which always holds good. The surface of such a self-luminous sphere emitting pure white light cannot be distinguished from a non-self-luminous sphere dead white, reflecting or scattering cent. per cent. of the light falling on it, and illuminated from some external source with the illumination of one candle-foot. As a corollary of some interest in connection with dead white reflectors, it may be remarked that a perfect white reflector of one square foot illuminated with π candle-feet emits one candle-power normally.

In one case we have been obliged to depart from a close verbal translation of Mr. Blondel's nomenclature. He uses *éclairement* for illumination in the ordinary sense of the word; but when he comes to the two time units, he employs the less common French word *l'illumination* to denote the quantity which is, perhaps unscientifically, calle l a "candle-foot-second." Such a unit has been proposed in connection with photography, and it would be of immense practical importance in that art. It is nothing more or less than "exposure" in the photographic sense. It is true that the photographer measures his exposure as a time only, but the degree of illumination is suppressed. He chooses a period which shall, under the circumstances of illumination, give a desired chemical result. For all practical purposes this result is determined by the product of the time into the illumination. We hope that Mr. Blondel's important article will draw attention of physicists to the nomenclature of photometry. It is most unfortunate that π should intrude so often, and give rise to such complications, but owing to a lamentable anomaly of the space in which we live, this embarrassment is unavoidable.

PHOTOMETRIC MAGNITUDES AND UNITS.*

BY ANDRÉ BLONDEL.

Of all branches of Physics, photometry is the one whose system of units has been the least improved. Whilst the vocabulary of Electricity has been daily added to, and the supply of electrical units has become almost in excess of the demand,† some of the units being, indeed, left somewhat out in the cold, the Electrical Congresses which have been successively held since 1881 appear to have thought that photometry only needed a good standard of light. But this was too optimistic a view, and there is to-day a reaction against it. Does this mean, as has been urged, that photometry is a science requiring recasting? Certainly not, since the few physical principles upon which it is based are firmly established, and cannot give rise to any objections. Photometric phraseology is, however, to my mind, open to criticism, and the number of units is insufficient. I propose in this article to briefly justify this apparently subversive assertion, and to put forward a simple system of units and definitions fulfilling the desiderata which I shall point out. I trust my readers will not take exception to the somewhat irreverent manner in which I shall, perhaps without reason, criticise the existing state of things, but that they will only take my good intentions into consideration.

Imperfections of Existing Definitions.

Photometry has retained without much alteration the phraseology which it has received from the eighteenth century. This is doubtless to be explained by its poor theoretical development, and by the forcedly limited field that it offers to investigators. It is not, however, a sufficient reason for perpetuating anachronisms such as the definition of quantity of light and the units in use. Classic phraseology gives the name of "quantity of light" to the *flux* of light, and thus puts itself into contradiction with the termi-

* From *La Lumière Électrique*.

† The few gaps that remained have been filled in advance by the recent proposals of the American Institute of Electrical Engineers, which, on the initiative of Messrs. Houston and Kennelly, has elaborated a system of concrete magnetic units in every way deserving of success.

Digitized by Google

nology adopted in the study of Heat, an agent which is nevertheless analagous. It would never enter the mind of anyone to-day to confound quantity of heat Q with the flow Φ; for the first is equal to the product of the second into the time [Q = Φ T]. Why make this confusion in photometry, when no advantage is to be derived from so doing? It is the height of unreason. Indeed, it is in my opinion desirable henceforth to make use of the notions of *flux* and of *quantity* of light in exactly the same way as in Heat.

It would also be a good thing to get rid of the word "brightness" (*clarté*), which each author uses in a different sense, and to definitely allot the word "brilliancy" (*éclat*) to the intrinsic brilliancy of the sources of light.*

On the other hand, it is necessary to protest against the singular idea which people too often appear to have about the part played by units. There are, in fact, no less than six fundamental photometric quantities: intensity (*intensité*), flux (*flux*), illumination (*éclairement*), intrinsic brilliancy (*éclat intrinsèque*), time-illumination (*illumination*), and quantity of light (*quantité de lumière*), the last being connected with energy; and yet it is pretended that a single unit "the candle" will serve for all. To make use of this for all purposes, like Æsop wished to the tongue, is exactly as if we measured the different quantities which intervene in magnetic phenomena in terms of unit pole. Who, for instance, would dream of measuring magnetic induction in terms of "unit pole at a distance of 1cm"? Yet this is what we do every day in photometry when we measure illumination (*éclairement*) in terms of "a bougie at one metre." But this is not all: many people readily excommunicate, in an aggravating and amusing way, those who are not seduced by this strange expression, but prefer to confine themselves to the compound words "bougie-mètre" or "candle-foot," which, at least, do not pretend to define by their etymology the nature of the unit which they express, and which are only conventional terms.

If the notion of flux of light, which ought to be the fundamental one of photometry, is constantly misunderstood, as I have asserted, is it not simply because no special unit has been to express it in? The uninitiated, who instinctively feel that light spreads itself like water in all directions, are naturally bewildered when they see the luminous output measured in candles as well as the intensity. An American contemporary,† which gleefully collects photometric pearls, recently told an amusing story, the truth of which it guaranteed, which is a good example of this way of looking at the matter.

An expert, called in to interpret a clause in a public electric lighting contract between a town near New York and the local electrical company with regard to some 2,000 nominal candle-power arcs, expressed his opinion, it appears, as follows:—The arc lamps are suspended at the cross roads, and each one, therefore, sends out its light in four directions; one cannot, therefore, expect to get 2,000 candles in each direction. The 2,000-candle arc arranged for in the agreement was one sending 500 candles down each road.

We do not wish to make fun of this expert, for in truth he is a very sensible man. The quantity the most needful to be known in this instance was, as he rightly thought, the flux of light, and if photometry does not enable us to define a lamp with that in view, it is photometry which is in the wrong.

Photometry is still more faulty when it conceals the idea of flux of light under artificial names, often extraordinary and well-calculated to deceive the world, such as "volume of illumination" (*volume d'éclairement*), a quantity which is obtained by calculating the illumination of each point of the ground beneath the source of light, and then integrating the products of each illumination into the corresponding area. This volume of illumination is merely the flux of light emitted by the source over the corresponding solid angle, and therefore in no wise depends on the orientation of ground lit up. Why, then, instead of giving the quantity its proper name, compound this strange amalgam of photometry and geometry?

The confusion which exists between flux and intensity of light necessarily results in a corresponding ambiguity in the definition of "intrinsic brilliancy." With some‡ the intrinsic brilliancy of a source of light of uniform luminous intensity is equal to the quotient of the total quantity of light (read "flux of light") by the surface S of the light-giving portion of the source $i = \Phi/S$. With others§ it is the quotient of the luminous intensity measured in a normal direction to the light-giving surface; that is to say, $i = I/S$. These two expressions are evidently anything but equal,|| and, as in both cases the authors whom I have just quoted measure the brilliancy in candles per square centimetre, a fresh source of error arises.

All that has been stated leads to the irrefutable conclusion that a special unit should now be adopted for each different quantity, as is done everywhere else. Even in photometry, as a matter of fact, this step would not be a complete innovation, for some years ago the photographers, more progressive in this respect than the electricians, established under the presidency of eminent *savants* (MM. Abney, Cornu, Janssen, Sébert, Violle, &c.), a unit of time-illumination (*illumination*) specially applicable to photography, the "phot," of which I shall speak later.* The path cut for physicists, and especially for electricians, is to adopt analogous units, capable of forming with this one a coherent system directly applicable to practical cases.

An important question to be decided is what kind of names are to be chosen for the new units? I think the matter is already settled by the previous adoption of the "phot," and the names to be coined should therefore be taken from Greek and Latin roots and not from the names of celebrated *savants*. The pantheon of the units is, moreover, already sufficiently furnished to render it unnecessary to mutilate any more names, as was done in the case of Volta and Faraday, or to perpetrate any more jokes like that to which the "mho" owes its existence. International rivalries will thus be avoided. Moreover, Photometry, like Heat, is an autonomous science, and may be allowed to settle its units on different lines to Electricity, and, assuming that we confine ourselves to Greek or Latin roots, nothing is easier than to build up a manageable system of units such as the one of which I will now briefly explain the uses and definitions.

Units Applicable to the Different Photometric Quantities.

Let us pass successively in review the different photometric quantities enumerated above, and let us see how they are inter-connected.

(1) The *luminous intensity* of a source of light in any given direction is the ratio of the flux emitted over a small solid angle, having this direction as axis, to this solid angle.

The unit of intensity, or "violle," adopted by the Congress of 1881 and the International Conference of 1884, is defined by a concrete standard due to M. Violle, and perfectly satisfactory from the point of view of constancy, the capital point when choosing a standard. The Violle standard is the light, measured at right angles to the source, which is emitted by a sq. cm. of platinum at the moment of solidification.† In practice the "violle," having no success with lamp makers, whose nominal figures it reduced too much, the Congress of 1889 had to adopt a secondary *practical* unit, the "bougie décimale," equal to the twentieth part of the "violle"; this, excellent as a magnitude, is deplorable as a name. In fact, the "bougie décimale" is not the tenth part of any unit; it approximates the tenth of the carcel, but the carcel being current only in France, the qualification of decimal has no meaning abroad; "bougie vigésimale," or "vigésiviolle," or "demi-déciviolle," is what should have been chosen; but it would be so little attractive to talk of a lamp of 16 demi-déciviolles, that we must not be too severe with the Congress for having hesitated to adopt such nomenclature. The expression "bougie décimale" has the additional grave defect that it tends to confusion, since the decimal qualification is very often forgotten, so that if we see "candles," or "kerzen" mentioned, we have first to critically examine the context to find out whether English, German, or decimal candles, &c., are intended, things which are far from being the same. In Germany this confusion has already discredited the "bougie décimale," and for the most part the Hefner (H. L.) unit is employed, contrary to the decisions of the Congress of 1889. The very existence of the Violle unit is thus threatened, and at the recent Congress in Chicago the German *savants* demanded that it should be replaced by another unit. This demand, I think, arises from a mistaken view of the needs of photometry, since, although a good secondary standard may be wanted, that has nothing to do with the theoretical standard. This would not, however, certainly have happened had the same thing been adopted as practical unit, but with a new and unambiguous designation. The word "phot" would have done admirably, but as it is already adopted for time-illumination (*illumination*), as we shall see further on, we are obliged to choose another. Fortunately, the Greek word "pyr" ($\pi\nu\rho$ = fire or source of light) appears equally satisfactory; it has, indeed, been already put forward in England to denote a million candles; but it would be contrary to the now recognised rules to give a special name to a multiple. I propose, therefore,

* The *intrinsic* brilliancy is still often distinguished from the *total* brilliancy by applying this last term to the luminous intensity of the source. This use of the word brilliancy unfortunately gives rise rise to confusion.

† *Electrical World*, June 2, 1894, p. 729.

|| We shall see later on that when the source follows Lambert's law of emission, the ratio of the two expressions is π, so that the figures vary in the ratio of 1 to 3, according to the definition chosen.

* Brussels Photographic Congress (*Comptes Rendus*, p. 66).

† The phraseology adopted by the Conference "the unit of light is the *quantity* of light emitted in a normal direction by a sq. cm., &c.," seems to be incorrect, for either they wished to define the unit of *intensity*, which is not a *quantity* of light, or they wished to define the unit of *flux*, and then they should have said over what solid angle this was to be measured.

Digitized by Google

now to call the "bougie décimale," or the practical unit of intensity whatever it may be in the future, a *pyr*; using for big lights the *megapyr*, equal to a million *pyrs*. The "violle" would then naturally remain the primitive theoretical unit, and the *pyr* would only constitute the base of the system of practical units.*

2. The *luminous flux* (*flux lumineux*) Φ should have as a practical unit the flux which takes place over a solid angle equal to unity from a point source having the uniform intensity of one *pyr*. I suggest the word "lumen" for this unit. A source of light having a mean spherical intensity of *n pyrs* would thus have a total flux of $4\pi n$ *lumens*.

3. The *illumination* (*éclairement*) *e* at a point of a surface is equal to the ratio of the luminous flux which falls on a small element of surface to the area of this surface $e = d\,\Phi/d\,s$.

It is absolutely necessary to adopt a new name for the unit of illumination, and I am astonished that the Congresses of 1889 and 1893 did not recognise this necessity. The term "bougie-mètre" leads to confusion unless we state it is a question of the "bougie décimale," and the term "bougie-décimale-mètre" is not very handy to make use of when mentioning a unit. Finally, the metre not being yet in common use in England and America, one makes a great mistake if one anticipates that it will nevertheless be admitted in a compound word. As a matter of fact, in no English writings have I met with the expression "candle-metre," whilst on the other hand, the "candle-foot" is generally to be found. To insure uniformity in international terminology, which is the aim of every system of units, we must adopt a simple name in which the unit of length does not figure. A name is ready to hand; it is the "lux" proposed by Mr. Preece at the 1889 Congress, and which we will apply now to the "bougie-mètre." All who are in touch with the wants of practical photometry are in agreement as to the adoption of this word.†

According to the terminology previously indicated, the *lux* must be defined as "the illumination produced by an uniform source of one *pyr* on a surface at right angles to the rays, and situated at a distance of one metre," or, which comes to the same thing, "the illumination produced on a surface of 1 sq. m. by an uniform flux of 1 *lumen*." Inversely, one could define a *lumen* as the luminous flux capable of illuminating a square metre to the extent of *one lux*. The product of a certain number of *lux* into a surface computed in square metres will thus give a number of *lumens* representing the total flux received by this surface.

4. The *intrinsic brilliancy* (*éclat intrinsèque*) *i*, as I have already stated, has hitherto had two different meanings; I will only preserve the more usual one. The intrinsic brilliancy is the quotient of the intensity, measured at right angles by the surface of the emitting source $i = I/S$.

When a luminous body follows Lambert's law of emission, and we place before it a diaphragm pierced with a hole, the luminous intensity produced by the hole in the direction of its axis is independent of the orientation of the emissive surface placed behind; we say then that the intrinsic brilliancy is constant for all incident angles. In the contrary case we shall denote by the term "brilliancy at the angle α" the brilliancy of the hole when its axis makes the angle α with the normal to the incandescent surface. This generalisation of the notion of brilliancy is often very useful.

The practical unit of brilliancy is the intrinsic brilliancy of a source of light giving 1 *pyr* per unit of surface ($\frac{1}{20}$th of the brilliancy of the Violle standard). To be complete we should also define under the name of *intrinsic radiation* (*rayonnement intrinsèque*) ϕ the ratio of the flux of light emitted by the source to the emitting surface $\phi = \Phi/S$. This unit of radiation corresponds to a radiation of 1 *lumen* per unit of surface.

These two units have the same physical dimensions, and one might give them two special names, say the "*phane*," from the Greek root φαν, shining, and the "*lampsis*," from the Greek root λαμψισ, brilliancy; but to do so would be to uselessly complicate nomenclature, since we can simply express these units in *pyrs* per square centimetre or millimetre, and in *lumens* per square centimetre or millimetre; expressions which have no ambiguity, and will not give rise to fresh confusion.

In general there is no simple relation between the intrinsic brilliancy and the intrinsic radiation. But when the light-giving body follows Lambert's law of emission it is easy* to show that $\phi = \pi i$ and consequently that a brilliancy of *n pyrs* per square centimetre, correspond to an intrinsic radiation of πn *lumens* per square centimetre.

5. *Time-illumination* is by definition the product of the illumination (*éclairement*) *e*, to which an object is submitted into the duration of that illumination. The unit is the *lux-second*, that is to say, the time-illumination obtained by an object by an illumination of 1 *lux* prolonged for one second; this unit received at the Brussels Photographic Congress the special name of "phot." The *phot* plays an important part in photography, since chemical reactions appear to depend directly on the product $e\,t$. The same applies to certain physiological phenomena connected with the vision, a certain minimum time-illumination (*illumination*) is necessary before one receives a luminous impression; it is in *phots* that this should be expressed. One may assume that, generally speaking, there must be about 10^{-8} *phot* in the plane of the pupil to enable it to perceive, in ordinary practice, a punctiform source of light.

6. The *quantity of light* should no longer be confounded with the *flux of light*, as was previously pointed out. The *quantity of light* L is, by definition, the product of the flux of light into its duration. It is, therefore, equal to a *lumen-second*, and we might give this unit the name of "rad," which has already been proposed by certain photographers.† The *rad* may also be defined as the quantity of light received by unit surface (1 sq. m.) exposed to an illumination of 1 *phot*. We can thus express in *rads* the quantity of light necessary to produce a luminous impression on the retina. For commercial purposes it might be enough to measure the quantity of light in *lumen-hours* in the same way as we measure the quantity of electricity in ampere-hours instead of in coulombs. The *lumen-hour* could be made the basis of lighting contracts, as we shall see further on.

The quantity of light for a radiation of given wave-length is proportional to the energy of the radiations; one might, therefore, like to denote it in ergs, as with other forms of energy. But when polychrome sources of light are in question, this datum no longer has any simple relation with the photometric effect produced, since each radiation has a different coefficient of physiological action. The total energy of luminous radiations is, therefore, only of indirect interest in this matter, and it is desirable to keep it separate from the idea of quantity of light as just defined. Energy proper only comes in in laboratory researches.

Examples of the Application of the New Units.

The suggestions I have just made would not be complete if I did not show how to make practical use of them. I propose, therefore, with this object in view, to give a few examples of different kinds solely to show how to employ the new units, and without pretending to propound any theory properly speaking on the matters to which I adopt them.

Example 1. Measure of the Luminous Effect of an Arc Lamp.—Generally speaking, it is not too well known what is meant by a lamp of so many candles, and European engineers, discouraged by the continual misunderstandings on this point, have mostly given up designating arc lamps other than by their electrical constants.‡ This solution may be convenient, but it has the grave defect of rendering it unnecessary for the companies to trouble themselves about the quality of the carbons and their efficiency as light givers. Now, the uncertainty that arises is due, as a rule, to the fact that the makers do not state whether they mean horizontal intensity, maximum intensity, or mean spherical intensity. The uncertainty would, consequently, disappear if they would agree to designate lamps by their total flux expressed in *lumens*, which is equal to their mean spherical intensity multiplied by 4π; a lamp of 30 spherical carcels would thus become a lamp of 3,770 *lumens*. This new system would have the advantage, so far as lamp makers are concerned, of resulting in bigger figures than the present system, and, so far as the public is concerned, of leading to no confusion whatever. Since in these days the average shape of the curve giving the distribution of candle-power of arc lamps is well known, the information as to the *lumens* would alone be quite enough. This might, however, be usefully supplemented by stating how many *lumens* are emitted above and below the horizontal; this last

* There would be another advantage in adopting a new name such as the *pyr*, namely, that it would henceforth give a scientific stamp to light measurements; the common word "candle" leads one to suppose that one is dealing with an empirical unit without scientific value. At present everyone who knows what a stearine candle is thinks he has mastered photometry, much in the same way as every man who knows how to read and write thinks he understands philosophy. When he is talked to about *pyrs*, he will more readily admit that a certain apprenticeship is requisite before one can usefully discuss questions of lighting.

† *See* especially Palaz: *Traité de Photometrie.* This question was raised at the Société des Electriciens in connection with the Chicago Congress programme. But the French Committee, which seems to have endeavoured before all things to avoid every innovation, did not admit this matter into its list.

* If we call I_a the luminous intensity produced at an angle α by an infinitely small element of incandescent surface, we have by Lambert's law, $I_a = I_0 \cos\alpha = i_0\,d\,S\cos\alpha$, i_0 being the intrinsic brilliancy along the normal; consequently the total flux

$$d\,\Phi = \int_0^{\frac{\pi}{2}} i_0\,d\,S\cos\alpha \times 2\pi\sin\alpha\,d\,\alpha = i_0\,d\,S \times \pi,$$

whence $$d\,\Phi/d\,S = \pi\,i_0.\text{—Q. E. D.}$$

† Abel Buguet. *Journal des Sociétés Photographiques*, May, 1892.

‡ American engineers have recently come to a singular decision on this subject. By them every 10-ampere lamp will in future be called "a lamp of 2,000 candles" even if it only gives 500 or 600. This is a sad precedent, and an example to avoid.

Digitized by Google

figure is, in fact, the only one of any use in public lighting, as we shall see further on.*

Example 2. *Effect of a Projector.*—I propose to define the electric arc, and beam of a projector. Let us assume an arc having 1 sq. cm. of crater placed at the focus of a projector having a cross section, S, of 1 sq. m. at the base of the beam, an absorption of 20 per cent., and a mean coefficient of optical utilisation of $\lambda = 0{\cdot}5$. Let us assume that the crater is sensibly plane and has an intrinsic brilliancy of 160 *pyrs* per square millimetre. The intensity of the arc in a direction normal to the crater will be $100 \times 160 = 1{,}600$ *pyrs*. Again, the emission following sensibly Lambert's law, the intrinsic radiation is, as we have seen, $\phi = \pi i$, and the flux produced by the crater $\Phi = \pi \times 16{,}000 = 50{,}000$ *lumens*. The total flux, taking into account the light of the arc and of the negative, will be about 20 per cent. greater. Only a portion of this flux will fall on the active surface of the apparatus. The flux can in each particular case be measured by means of direct photometric measurements: for instance, if it is a case of a horizontal lamp, the useful portion of the curve of distribution can be planimetered. Supposing the corresponding flux equals 30,000 *lumens*, since the projector absorbs 20 per cent., the *emergent beam* would finally be one of about 24,000 *lumens*.

The *luminous power* (*puissance lumineuse*) of the projector, according to the definition of this quantity usual in the case of optical apparatus, that is to say, the luminous intensity of a naked light giving the same illumination at a great distance along the projecting optic axis,† is approximately expressed, as I have recently shown,‡ by the equation $P = \lambda\ S\ i$; that is to say, in this case $P = 0{\cdot}5 \times 1{,}000{,}000$ sq. mm. $\times\ 160$ *pyrs* = 80 *megapyrs*.

The *maximum* illumination on a surface normal to the axis of the beam may be calculated from this figure from infinity to a certain critical distance by the law of the square of the distance. If the distance l is expressed in metres we get $e = 80{,}000{,}000 / l^2$ *lux*: at one kilometre, for example, $e = 80$ *lux*. Beyond the critical distance, which is always relatively short, the number of *lux* increases more slowly, according to a law which depends essentially on the shape of the optical surfaces employed. At all distances the *mean* illumination in *lux* of a section through the beam is equal to the quotient of the total flux in *lumens* by the area of the section in square metres. If the beam is cut as it emerges from the apparatus the mean illumination obtained is $e = 24{,}000$ *lumen*/$1\text{m}^2 = 24{,}000$ *lux*. Generally, if a be the radius of the base of the beam, and b the tangent of the angle of divergence, the *mean* illumination of circular area illuminated at a distance, l, will be by the formula $e_m = 24{,}000 / \pi (a + b\,l)^2$ *lux*. Here we have $a = 0{\cdot}6$m., and if we suppose that $b = 0{\cdot}02$ we shall find at 1,000 metres that $e = 68$ *lux*, which is a different figure to that which we found for the *maximum* illumination along the axis.§

We thus see that the three fundamental units have their uses here in enabling us to easily distinguish the different kinds of effects produced by the projector, and thus to avoid all misunderstanding.

Example 3. *Public Lighting.*—Let us assume that a public thoroughfare is lit by arc lamps, and that it is required to know the *mean* useful illumination obtained. One could determine the curve of distribution of the arc when surrounded by its globe, and plot, according to the well-known method, the lines of equal illumination.* In this way we could determine the maximum, minimum and mean illuminations. But this delicate research is useless if the only thing required to be known is roughly the average illumination of the roadway, trees, and house-fronts. To obtain this it is sufficient to measure, by means of the intensity curve of the lamp, the flux sent out by it below the horizontal, planimetering the corresponding part of the transformed curve (Rousseau's method) multiplied by 2π.† The product of this flux into the number of lamps divided by the total illuminated area in the street in square metres gives the mean illumination in *lux*;‡ for, as we know, one *lumen* is the flux capable of illuminating 1 sq. m. by one *lux*. The flux is thus an approximate measure of the useful effect of the lamps. When a town buys light for its streets from a company, it might, I suppose, pay for it according to the number of *lumen-hours* supplied during the year below the horizon, and I do not think it would be impossible to draw up lighting contracts in this form.

Example 4.—*Interior Lighting of a Ball Room.*—The illumination at any point in an enclosed space varies according to the direction of the surface on which it is measured; the maximum illumination is the intensity of the luminous field in the same way that the density of the magnetic flux in air is the intensity of the magnetic field. The eye, however, as a rule judges of the illumination of a room by the average illumination, e, of the walls. This, to give the same useful effect, should be inversely proportional to the diffusing power d of these walls. We thus have, taking k as a constant, $ed = k$. If we call a the absorbing power, and S the total superficial area of the walls, we find, neglecting the effect of the furniture, &c., that the total luminous flux which it is necessary for the lamps to produce should equal the flux absorbed:

$$\Phi = a\,e\,S = S\,k\,\frac{a}{d} = S\,k\,\frac{a}{1 - a}.$$

That is to say, it should be proportional to the *total* superficial area of the floor, roof and walls of the room,§ and a certain number of *lumens* are required per square metre. Where incandescent lamps are employed, since the flux is equal to the product of the nominal intensity in *pyrs* into a constant, special to each lamp, we can practically say, "So many *pyrs* are required per square metre"; but this is at bottom a bad way of expressing the matter, and it is better to keep to the first. For example, if $k = 5$ *pyrs* and the coefficient of absorption of the walls $a = 0{\cdot}60$, 7·5 *lumens* will have to be produced per square metre of floor, roof and walls. The preceding formula has the advantage that it takes rational account of the area and nature of the walls of the room.

Conclusion.

I trust I have shown by these different examples all the advantages of constantly bringing into photometric calculations the notion of luminous flux, of pursuing the usual plan of applying to quantities of different nature equally distinct units, and of dispensing with the anti-scientific word "candle," which now gives rise to continual misunderstandings.

Physical quantities.	Symbols and defining equations.	Dimensions.	Names of the practical units.
Luminous intensity ...	I	[I]	*Pyr*, or "bougie-décimale," $\frac{1}{20}$ violle.
Luminous flux	$\Phi = I\,\sigma$.‖	[I]	*Lumen*.
Illumination	$e = \frac{\Phi}{S}$	$[I\,L^{-2}]$	*Lux*.
Intrinsic brilliancy......	$i = \frac{I}{S}$	$[I\,L^{-2}]$	*Pyr* per sq. cm.
Intrinsic radiation	$\phi = \frac{\Phi}{S}$	$[I\,L^{-2}]$	*Lumen* per sq. cm.
Time-illumination	$j = e\,t$	$[I\,L^{-2}\,T]$	*Phot*, or *lux second*.
Quantity of light	$Q = \Phi\,t$	[I T]	*Rad* (or *lumen-second*) *lumen-hour*.

The system of units which I propose is summed up in the little table above. I take intensity as the fundamental magnitude in

* The idea of flux is the most natural one to employ here, since it corresponds to a real quantity, whilst the mean spherical intensity is a fictitious constant. If people had always considered the flux they would not have committed the grave error, which is to be found in nearly all books, relative to the well-known formula,

$$\text{I mean sph} = \frac{M}{4} + \frac{H}{2},$$

which gives the mean spherical intensity of a continuous-current arc as a function of the horizontal intensity H and the maximum intensity M, and which may also be written thus—

$$I = \frac{H}{4} + \frac{H + M}{4}.$$

The authors, as a rule, say that the first term may be taken as representing the mean superior hemispherical intensity and the second the inferior, when they should say

$$\text{I hemi. inf.} = \frac{H + M}{2},$$

$$\text{I hemi. sup.} = \frac{H}{2}.$$

A mistake of this kind is not possible when we consider the flux above and below the horizontal, for if a lamp gives 1,000 *lumens* below the horizontal, and 200 above, the total flux is evidently 1,200 *lumens*, the mean spherical intensity being $1{,}200/4\pi$ *pyrs*, and the hemispherical means respectively $1{,}000/2\pi$ and $200/2\pi$ *pyrs*.

† This might be more clearly called the *tele-intensity* of the projector.

‡ *See* "Théorie des Projecteurs Electriques," published by A. Lahure in Paris, Rue de Fleurus.

§ The value of the mean illumination is in general without interest; what is important is the maximum illumination along the axis at a distance greater than the critical. That is why a projector is usually defined by its nominal power (theoretically determined) or its true power (experimentally determined).

* Interesting examples of the application of this method will be found in the remarkable work of M. Maréchal on the lighting of Paris, in which it has a most happy extension in so far as public lighting is concerned.

† If we employ a globe of which we know the hemispherical efficiency below the horizontal, this operation is unnecessary. All we want to know is the values of the fluxes in *lumens*, and to multiply them by the coefficient of the globe.

‡ This is so, regardless of the angle of the illuminated surfaces at each point. The same method applies to the determination of the illumination of a circular area having as centre the foot of the supporting post. The planimetering of Rousseau's curve should in that case be restricted to the angle subtended by this circle.

§ The reasons which are brought forward to prove that it should be equal to the volume do not seem to me to be very clear; at any rate, they do not show the error of the above reasoning.

‖ σ solid angle; dimension: a number.

Digitized by Google

accordance with present usage, without, however, endeavouring to connect it with others, because it is a physiological rather than a physical quantity. This system of units, being entirely in conformity with those dealing with electricity and magnetism, could be adopted, with modifications if need be, for the same reason as its predecessors; it is, indeed, difficult to understand why that which is unanimously recognised as useful and even necessary in every branch of physics should, without proof, be deemed superfluous in photometry.

THE LIVERPOOL OVERHEAD RAILWAY.

(*Concluded from page 601.*)

Mr. M. FITZMAURICE observed that, so far as could be gathered from the Papers, and the information was only gained from the expression "iron viaduct," the floor and the main girders were of iron and not of steel. He would like to know what led to the adoption of the former metal instead of steel, particularly for the floor. Many engineers would doubtless not use steel in the atmosphere of towns, as it was stated to rust quicker than iron under such conditions; but that might be easily prevented by effective painting, and the design of the structure under consideration seemed to lend itself easily to being kept in repair as regards painting. Another reason might be that as the rolling loads were comparatively light (a fact which was well represented in the small ratio of depth to span in the main girders), it might not have been possible to take full advantage of the extra strength of steel in the way of diminishing sections. That, of course, would only apply to the main girders, and not to the floor. The floor described certainly possessed many advantages over other modern trough-floors, especially when used with two main girders as in the present case, in contradistinction to three main girders. When used as an ordinary ballasted floor the lines of riveting on the under side must cause a good deal of leakage after a time; but when, as was sometimes done, the hollows were filled with light tar concrete with a layer of asphalte on the top, a good watertight floor was obtained. In either case the weight of filling was less than in the majority of trough floors. He supposed that there were some stiffening diaphragms in the length of each trough to prevent any deformation of the thin curved plates. The thickness adopted for the curved plates; viz., $\frac{5}{16}$in., seemed very little, and would, of course, only be justified in the case of a non-ballasted floor where the plates were easily inspected. He would like to know whether the pure asphalte, which was found to be the best material to cover the plates with, had shown any tendency to scale off under the vibration set up by the traffic, what thickness of asphalte had been used, and whether it had been applied in one or more coats. The junction of troughs with main girders was nearly always a leaky place, and he would like to know whether any difficulty had been experienced there; also, how the troughs were connected with the main girders between the stiffeners, whether with short lengths of angle-bars or with continuous angle-bars. When the former method was adopted the webs of the main girders, especially when of iron, were often seriously racked. Of course, there must be a good stiff connection, as the flooring acted as wind-bracing between the main girders. The pitch of the troughs did not appear to fit in with the ordinary 4in. pitch of riveting in the main girders. The flooring described was no doubt the best flooring that could have been adopted for the line under consideration, as the floor for a whole span could be riveted in place by hydraulic power. When, however, that type of flooring was sent down to the country in separate pieces, the riveting by hand ought to be carefully inspected, as it was not so easily riveted by hand in place as some other sections.

Referring to the difficulty of getting the curved plates to keep their shape while cooling, the same difficulty had arisen with some of the curved plates for the tubes at the Forth Bridge; and, after several trials, it was found that the best way to meet the difficulty was to squeeze the plates a second time in the hydraulic press when cold. The floor seemed to be remarkably stiff, as in the experiments carried out with it the deflection with 30 tons on three troughs was practically nil. The question occurred to him, did the experiments on the strength of the floor give any idea of what the actual strain in a trough was under the traffic which it had to carry? He thought not; and, after all, that was what was wanted to be ascertained. The principal thing which prevented one trough from taking all the load on one axle, when the axle was directly over it, was the rail (in the case in question, the longitudinal sleeper) distributing the load over adjacent troughs. The stiffness of the rail was, therefore, the principal thing to be considered. The stiffness of the floor had to be considered in a less degree. A very stiff floor did not give such a good distribution as a more elastic floor, within certain limits. In the case considered, the maximum weight on an axle could not be more than one-half that on an ordinary locomotive axle; the floor was not nearly so heavy as would be adopted on an ordinary railway, and the 56lb. flat-bottomed rail had probably not half the stiffness of an ordinary 80lb. double-headed rail. He did not wish for a moment to insinuate that the stresses in the floor under consideration were more than ought to be allowed, as, during the twelve months in which a five-minute train service had been in force, any weakness would soon have been detected. But it would have been of interest to know what the actual working-stress in the floor was and over how many troughs the load on one axle was distributed. It was very difficult to determine this in ordinary trough-floors without a good deal of expense and elaborate preparations. In the case under consideration it could easily be determined by means of stress-gauges, such as the Stromeyer gauge, as it was possible to attach them directly to the floor. A most interesting experimental determination of the actual stresses in the troughs could, therefore, have been made with different sections of rails, which would have been very useful for future reference. Some assumptions must have been made when designing this floor, such as over how many troughs the weight on an axle was distributed, and whether the troughs were to be considered fixed or free at the ends. It would be interesting to know these points, and also whether they were found to hold in practice.

The New York Elevated Railway had been mentioned in the Paper, but it was difficult to compare its actual constructive cost per mile with that of the Liverpool Overhead Railway. Of course, in both cases, allowances would have to be made for the differences in cost of labour and material at times of construction.

Mr. JOHN HAYES remarked that, whilst every credit was due to the foresight of Mr. Lyster, the engineer to the Liverpool Dock Board, in seeing almost from the first that electric traction was likely to be the most suitable for the line described in the Papers, it was, in the light of subsequent events and after the undertaking has been brought to a successful issue, somewhat difficult to conceive how any other system of traction should have been seriously entertained by its promoters. Alongside the greater part of the railway at Liverpool, and in close proximity to it, were huge warehouses, generally filled with cotton, grain or other highly combustible material; in addition to which, shipping at the various docks, and cargoes on or about the wharves, added to the serious risk and danger which would have been ever present had steam locomotive engines been adopted as the motive power, with the possibility of sparks from the chimneys of such engines.

A matter of no little importance in connection with the construction of the line, not referred to by the authors, was that the contractor had placed the manufacture of nearly the whole of the heavy main girders carrying the railway, as well as the swing-bridge at the Stanley Dock, with a local firm, and thus close to the base of operations; and as it had fallen to the lot of Mr. Hayes, as the General Manager of those works, to supervise the manufacture of some 5,000 tons of the plate girders, as well as castings and other important work, he might say without hesitation that the course adopted had greatly facilitated the execution of the work—far more so than perhaps anyone not directly concerned might imagine. With a view to minimise the cost and trouble involved in a contract of such magnitude, it was true, as the author had pointed out, that the normal span adopted for the girders was 50ft., but that had to be departed from in many places to avoid interference with existing lines, roads, gateways, and other structures; and, even in many cases within Mr. Hayes' knowledge, where the normal 50-foot span was adhered to, there were exceptional features introduced as the work proceeded, which constituted such girders, in every sense of the word, "special."

As regarded the details of manufacture in connection with the wrought-iron girders, although they were of the usual character followed on such works, a few remarks might not be out of place. The whole of the plates were delivered on the works from Middlesbrough by rail, in suitable lots, and, after levelling, were placed on plate-edge planing machines, all drilling of angles, plates, &c., being carried out under multiple drilling machines; the T-iron stiffeners for the web of girders were all bent or "joggled" hot under hydraulic presses, the ends of the stiffeners being afterwards cut off with cold circular saws; whilst the riveting was effected by pneumatic riveters on the Allen system, the working pressure (air) being 70lb. per square inch at the receiver. When completed, the girders were lifted by powerful overhead cranes on to railway trucks, and were delivered direct on to the site of the Overhead Railway in Liverpool. The same economical principle of local manufacture had been also followed in the manufacture of the Hobson arch-plate flooring, which had been adopted throughout the railway, at a yard at the north end of the line or upon the actual site of the work.

Mr. CLAUDE W. HILL remarked, in regard to the Eickemeyer system of winding, that the author of the second Paper had been the first in this country to recognise its merits and to adopt it. The advantage which it gave of enabling a damaged coil to be removed and replaced with a good one, without having to strip the entire armature, constituted a great advance over the ordinary

Digitized by Google

construction of wire-wound drum armatures. A somewhat similar system applied to bar-wound drum armatures would offer considerable advantages. In the present system of constructing those armatures, a series of radial or spiral connectors was mounted at each end of the armature, and the bars were then laid on the periphery and joined to the end connectors by solder. Those joints greatly increased the resistance of the armature, making it two or three times greater than if the conductors were of solid copper; and there was the further disadvantage that the heating due to the soldering was liable to injure the insulation. If the bars and connectors were joined together first, and were then mounted on the armature, the joints could be thoroughly brazed or electrically welded, thus materially reducing the resistance of the armature and avoiding risk of injury to the insulation, as the insulating of the conductors would be done after the jointing. In order to see if such a construction were mechanically possible, he had a rough model armature constructed on this principle a few months ago, and had found that such construction was quite feasible.

Mr. Lincoln Moss, of New York, observed that the first Paper mentioned the New York Elevated Railways as having no parapets. The Sixth Avenue main line was a parapet structure, the tracks running between two outside pin-connected through trusses. His experience was decidedly in favour of deck structures with well-designed guard timbers and rails weighing 90lb. per yard. The excellent floor system of the Liverpool line could not be used in New York, as an open-work structure was required, to cast the last possible shadow. Drip pans were there used on the locomotives, and under the structures over the crosswalks. His experience was also adverse to close columns. As regards motive power, it would have been a mistake to have equipped the Liverpool line with steam locomotives. Since the Manhattan Railway Company experimented with an electric locomotive in 1889, wonderful progress had been made. At that time, he had reported that a two-fold increase in the efficiency attained might be anticipated, making the cost of electric traction, including fixed charges, $2\frac{38}{100}$ times as much as with steam locomotives. That prediction of four years ago had been exceeded, and the best electric railways in the United States give more than three times the efficiency found in his tests. The electric locomotive had then but a single reduction motor—at that time the economy of using two or more motors in series-parallel combinations was not appreciated—and the speed was controlled by varying the field strength and introducing external resistance, causing enormous losses. He had taken a 400-H.P. card when the electric locomotive was exerting only 10 H.P. on the train in starting. The cost of electric machinery had also been reduced by more than one-half in four years. He could not see why the Liverpool plant was not direct-coupled instead of rope-drives being used. The motor car was certainly preferable to a separate locomotive, costing less at first, reducing the non-paying weight to a minimum, and being cheaper to work and to maintain. The fuel consumption on the Manhattan Elevated Railway averaged 42lb. per train mile, including heating the trains. The standard trains weighed 110 to 130 tons loaded. The best locomotives on that line averaged a train mile on less than 30lb. of coal. The cost of construction and working in Great Britain was evidently much less than in the United States, where a mile of first-class elevated road cost £100,000 to £120,000, without rolling stock. It was hardly fair to compare the cost of equipment and working per mile of the Liverpool line with that required for the New York lines; for during the busy hours of the day the trains in the latter city were only 1¼min. apart, giving 450 tons per mile to be moved, whereas the Liverpool line, working 5½ miles of road on 5min. intervals, with trains weighing 39 to 50 tons, had only 96 tons per mile to be moved. In New York there were also long gradients of 1 in 50, and curves of 90ft. radius.

Mr. O. F. Nichols stated that the Liverpool Overhead Railway had attracted great attention in America on account of its low cost, and because it was the first permanent elevated railway operated by electricity. The construction of the closed floor, possible under the special conditions, increased the weight of the structure, but did not materially increase the general cost, while it furnished a neater and more permanent floor system than was practicable on the American lines. Comparing the structure with about three miles of line completed in Brooklyn within the past year, following part of the Fifth Avenue line, the following points might be of interest. The Brooklyn line was worked by steam locomotives weighing 28 tons each, drawing three to five coaches of about the same length as the Liverpool carriages, and weighing 16½ tons each when loaded, with full seating capacity for 48 passengers. The American lines encouraged standing loads, and carriages frequently carried 80 passengers, then weighing about 19 tons each. The portion of line referred to was an extension of the Brooklyn system, which now had 20 miles of line in four different branches.

The weight of the new steel structure of the Brooklyn line was about 3,000 tons per mile. The total cost, with an allowance for rolling stock of sixty coaches and nineteen locomotives for 3½ miles of line, was practically the same as for the Liverpool line, £90,000 per mile. An excess of about 20 per cent. in weight of structure was imposed by the necessity of spacing the bearing columns inside the curb lines of the street, at about 45ft. apart transversely—the track girders being spaced in pairs, one girder nearly under each rail, and the tracks 28ft. between centres. This permitted the use of island stations, which were much more convenient and economical in operation than outside stations. The erection, by a traveller with three booms on the front end—one of 30ft. long on each side and a central boom 75ft. long—seemed to have been effected with greater rapidity than at Liverpool; partly, no doubt, from the possibility of delivering the material on the street, whence it was hoisted into position. Under favourable conditions, twelve spans of 52ft. each were erected in one day, representing about 350 tons of material and 625 linear feet of structure. It was difficult to understand how an important line could be worked satisfactorily with one large and three smaller swing bridges at or near the middle of it. The traffic on the Liverpool line was about one-seventh of that on the Brooklyn line, about one-thirtieth of that of the New York lines, and about 20 per cent. less than that of the Fifth Avenue branch of the Brooklyn lines.

The use of electricity on the Liverpool line rendered it highly interesting to those who had given much study to the problem of city railways. The results, as given in the Papers of Messrs. Greathead, Fox and Parker, naturally led to comparisons with those of other lines—so far, it must be admitted, to the advantage of the Liverpool line. The electrical conductor and collector were simpler, and in every way better, than those used on the Intermural Railway at Chicago. Those employed at Chicago could not have been used had there been switches and turn-outs on the line. The method of obtaining power for the Intermural line precluded the possibility of obtaining accurate information as to the cost of working; which was, however, placed at about the same value as for the Liverpool line.

Should the developments of dynamos and motors continue to improve as they have done during the past four years, no one would think of operating the elevated railways of the future by any other medium than electricity. With the introduction of electricity would come shorter, lighter, and more frequent trains, with the avoidance of shunting at terminals, and the reduction of staff. It had been clearly demonstrated that high speed could not be maintained with frequent stops; 15 miles an hour seemed to be about the maximum average speed between terminals with stations less than one quarter of a mile apart. Once considered as a question of weight and power of locomotive, high speed for such service had come to be regarded more as a question of acceleration and retardation. For still greater speed there must be express lines with long runs. The conditions for maximum speed were, that stations should be as far apart, and gradients and curvature as light as practicable; acceleration and retardation, and facilities for loading and unloading passengers the best attainable. A table appended would illustrate results obtained as to station-spacing, time and speed. It was not exhaustive or minutely accurate, being merely certain average values on several lines.

An increase in the weight of locomotives by 10 per cent. on the Brooklyn line decreased the time in starting about 10 per cent.; but it retarded the time of stopping a little more than that, owing to the greater momentum of heavier engines and the inability of drivers to make quick stops with the vacuum brakes in use. The working expenses on three elevated railways are given.

The ton mile included coaches, but excluded motors. In the third column for American lines, the cost of train, wages and coal were reduced by one-half to make them correspond more fairly with the Liverpool line; it was, however, difficult, owing to varying conditions, to make such comparison absolutely just. Owing to the small traffic on the Liverpool line, it was not surprising to learn from the half-yearly report to the shareholders on February 13th, that the working expenses were £13,623, or 74 per cent. of the gross earnings, as against 56·7 per cent. for the Brooklyn lines, and 50·7 per cent. for the Manhattan lines for the year 1891. If the train mileage was taken for the entire half-year, at the same figure as for the third quarter, or 40,440 miles per month, the total for the half-year should be 242,640. The working expense of £13,623 probably covered maintenance of way and station service not included in the Table given. Those items amounted on the American lines to 20 per cent. of all the working expenses. If taken at the same rate for the Liverpool line the net working expenses for the half-year on the basis of the Table amounted to 10·894 pence per train mile as actual cost, against 4·017 pence as the average for the months of July, August, and September, given by the author of the second Paper. Probably some details were omitted, or not fully explained, which would account for the apparent difference between the results given in the Paper and those deduced from the reports to the shareholders.

Dr. Du Riche Preller thought that the conclusions of the authors concerning the superior advantages of motor-cars as compared with electrical locomotives were only applicable to certain local conditions, like those of Liverpool. Having lately had occasion to devote attention to comparisons of that kind, in view of several electrical lines with which he was at present occupied in Switzerland, he had found that it was very hazardous to generalise, and that each case must be judged on its merits. He had found, for instance, that on steep gradients the train load for 50 passengers by motor-car, electrical locomotive, and steam locomotive was 1 to 1½ to 2; but, on ordinary gradients, the proportion was very different as the number of cars increased. With two or three cars the weight was about equal; with four cars the electrical locomotive possessed a decided advantage over motor-cars. Moreover, the electrical locomotive ensured easier and safer manipulation of the train by one man, greater space for lodging large motors, easier attendance, and a saving in repairs. The power and traction expense at Liverpool of 4d. or 3·5d. per train mile was certainly moderate, but by no means phenomenal; indeed, having regard to the practically level character of the line, to the low cost of fuel (averaging 10s. per ton), to the low coefficient of friction, and to the large train mileage, he would have expected them to be less. On the Marseilles line, for instance, which had rising and falling gradients as high as 1 in 16, and where briquettes cost at the lowest 20s. per ton, the cost of power and traction was a little over 3d. per train mile; at Florence, with continuous gradients up to 1 in 20 and 1 in 12·5, and briquettes at 30s. per ton, the cost was 4d. At Buda-Pesth and on other lines in Europe, 4d. covered the entire working expenditure. The total working expenses at Liverpool had been up to the present time 13·5d. per train mile, and had absorbed no less than 86 per cent. of the receipts; whereas, even on the City and South London line, which was in every respect worked under far less favourable conditions, they were only 66 per cent., and on many other lines well within 50 per cent., which, with electrical traction, might be regarded as the normal rate.

With regard to the electrical plant, he wished to ask the authors to state what, in the dynamos, was the total loss due to the armature resistance, hysteresis and eddy currents; what was the maximum loss of potential at the end of the line, and the mean loss on the line; what system of lightning-arresters, if any, was used: and lastly, what was the sectional area of the copper bonding at the joints of the rails in relation to that of the rail and conductor section? American practice tended to very heavy bonding, the reason for this being the frequently defective permanent way of American lines. The increase in the weight of rails up to 90lb. per yard, as at Philadelphia, was *per se* no effectual remedy. Girder rails for tramways were used both on the Continent, where they were first made by the Phœnix Works, and in England up to 110lb. per yard; but, being generally laid direct on the ground without cross or longitudinal bearings, a subsidiary wire running under the head of the rails was always required to prevent considerable leakage. Extensive corrosion of gas and water pipes occurred on certain trolley lines where the current was made to pass from the rails or subsidiary wire through the cars to the contact wire instead of *vice versâ*. That system had the advantage of the arc forming on the arc as positive pole and thereby saving the contact wire; but it required high insulation of the permanent way; and, where that was wanting, electrolytic action by erratic watts or shunt currents would obviously occur.

With reference to the motors of the Liverpool cars, the Eickemeyer cool winding was neat and ingenious; but in the design of the motors as a whole, Dr. Preller thought the contractors of the electrical plant might have done better; and, in order to make this clear, he would compare the Liverpool motors with those constructed by Messrs. Brown, Boveri and Co., of Baden, Switzerland, for the Heilmann electrical locomotive. The steel-clad, gearless motors, of which there were eight in that locomotive, one to each axle, were four-poled, and the Gramme armature consisted of 136 coils of six turns, each placed in grooves and Pacinotti teeth, the wire being 8·2 square millimetres in section. The resistance of the steel field-magnets was 0·74 ohm, and that of the armature 0·125 ohm, being considerably less than that of the Liverpool motors, which had been given by the author of the second Paper as 0·37 ohm and 0·67 ohm respectively. The weight of the motor was 2·7 tons. At 310 revolutions per minute, corresponding with a speed of 40 miles per hour (the diameter of the wheels being 3·8ft.), and a pressure of 410 volts, the motor gave 60 H.P.; at 388 revolutions (or 50 miles per hour), 75 H.P.; and at 450 revolutions (60 miles per hour) the tested maximum power was 80 H.P. Taking the power of the Heilmann locomotive motors at 75 H.P., and that of the Liverpool motors at 47 H.P., and their weight at 2·7 tons and 2·5 tons respectively, the comparative weights were 72lb. and 116lb. per H.P.; in other words, the motors referred to gave, at less weight per unit, considerably more power than those used at Liverpool.

Mr. Mark Robinson expressed surprise at the statement made in the second Paper to the effect that an efficiency of 88 per cent. had been obtained with horizontal engines driving dynamos by ropes. Not only so, but this 88 per cent. was merely an average, for in the appendix it would be found that one of the trials gave 88·8, and another 89·6 per cent., and this with the low mean cylinder pressure appropriate to a condensing engine. The dynamo, it was stated, had an electrical efficiency of 97·7, and if 1 per cent. only were allowed for losses by hysteresis and Foucault currents, and 0·7 per cent. for the increased friction from the three bearings (two of them with a side strain) against the one bearing of a direct-coupled dynamo, the commercial efficiency became 96 per cent.—a very fine result, if correct. Allowing to the engine even the high brake-efficiency of 91 per cent., there was a little over 87 per cent. combined efficiency for the engine and dynamo together. What, then, were the ropes about when 89·6 per cent. was reached? They must have been making power. Why not have more ropes?

He did not desire to enter upon a controversy as to rope-driven and direct-coupled generating plant, for the victory of the latter was beyond recall. All would concede, however, that when one got rid of the ropes one certainly cut out some loss of power, whether large or small, though what that loss might be was as yet somewhat a matter of opinion. Happily, some exhaustive trials were about to be carried out abroad, and, pending the report of those trials, he doubted if anyone would think it safe to assume the transmission loss at less than 5 per cent.; his belief was that it was much nearer 10 per cent. It was, in fact, obvious that, instead of 88 per cent., not even 80 per cent. combined efficiency could be accounted for, except by a combination of perfections in engine and dynamo which no one could believe in without the strongest evidence.

But the evidence against those figures was not only their inherent improbability. He had had the advantage of speaking with an eye-witness of the trials, an engineer, in fact, who had taken part in them, and he had learnt, in the first place, that the indicator was fixed upon a pipe joining the two ends of the cylinder, and thus was connected with either end only through a pipe of

Digitized by Google

considerable length and with undesirable bends in it. Everyone knew the effect of such an arrangement in reducing the size of the diagrams. In all probability the indicated horse-power was materially understated. In the next place, the water resistance behaved as water resistances generally do behave on such occasions, and it was impossible to maintain a steady current. The Kelvin hecto-ampere balance, perfect as it was in many respects, was an unsuitable measuring instrument under the circumstances stated; because, owing to its extreme sensitiveness, it could not easily be balanced with an unsteady load; a recording wattmeter ought to have been employed. What certainty, or what probability even, was there that the diagrams from the steam cylinders coincided in time with the electrical readings?

It was stated in the Paper that the trials lasted over three hours and a-half, and a statement was given of the coal used in that time, and the coal per electrical horse-power was worked out. But anyone familiar with boiler trials would know that a three and a-half hours' trial was almost useless, as a relatively small error in estimating the comparative weight of fuel on the bars at the beginning and end of the trial might produce most misleading effects. If anyone still supposed the figures to be reliable, let them be compared amongst themselves. Thus, take the last two columns in the first Table, p. 555. With the same revolutions, the same vacuum, practically the same steam pressure, there was 87·5 per cent. efficiency when the engine indicated 408 H.P., and 89·6 per cent. when it indicated 385 H.P., or 23 H.P. less. If one thing was certain about engine efficiencies, it was that a diminished load tended to reduce brake efficiency, not to improve it; yet here, with a lighter load, the efficiency increased. What would the engine-makers say to their condensing engines being debited with 2·96lb. of coal per indicated horse-power in order to bring out this amazing combined efficiency of 88 per cent.? If the coal used at Liverpool were credited with the evaporation of only 7lb. of water per lb. of coal (even with the help of economisers), they would have 21lb. of steam used per indicated horse-power, with the engines working at a favourable mean pressure, and with an excellent vacuum. He refused to believe that as much as he did the 88 per cent. combined efficiency. It might be supposed that results so extraordinary, and so contrary to previous experience, would, before publication, have been re-tested frequently, or at least certified by the names of independent and recognised authorities in the difficult science of engine testing. But there was no such authentication. If not challenged, such statements would remain on record as a stumbling-block in the way of truth. It was no imaginary danger, for those misleading figures had already been used to that end. He had actually received a letter from the United States, written before the publication of the Paper, in which its figures had been quoted as evidence that the supposed advantages of direct driving had now been disproved in England! He was sorry to find fault with any detail of a Paper of so much interest and value; but it was sometimes a duty to speak out.

Capt. H. RIALL SANKEY, R.E. (ret.), wished to call attention to a few of the anomalies in the load curves, Figs. 8 and 9 (*The Electrician*, Sept. 7). From these it would appear that the load on the engines varied very slowly, the maximum variation being about 400 amperes in about half-an-hour, and the average about 100 amperes. That was different from what occurred on other electric railways. It was also unlikely that on October 10th, from 5 to 9 a.m., eight trains would take nearly the same average load as twelve trains on the same day between the hours of 9 a.m. and 5.30 p.m.; whereas, on October 18th, eight trains took about 400 amperes average load against 800 amperes for the twelve trains. Again, on April 14th, when seven trains were running between 1.30 and 3 p.m., the average load was about 250 amperes, and yet on the same day, with the same number of trains running, the average went up to 800 amperes between 4 and 5 p.m. The solution of those anomalies was, however, not far to seek. It was stated in the Paper that the amperes and volt readings were taken once in every half-hour; and evidently those intervals were far too great in the case of a load varying as much and as suddenly as that on an electric railway. He had seen a load curve of the Liverpool electric railway for which readings had been taken every minute for one hour; and the result was entirely different from what was shown in the Paper, but agreed with those of other electric railways. It was important to notice that the load curves given in the Paper did not therefore give the real output of the plant; and the Table, showing amongst other things the coal burned per kilowatt-hour, was consequently unreliable.

Mr. JAMES N. SHOOLBRED found the Paper of special interest from the fact that his early days had been spent in railway work, then for several years his occupation had been among heavy iron constructions for buildings and for railways, and latterly he had devoted much time to the industrial applications of electrical energy. A lengthy residence in Liverpool had also made him acquainted with and appreciative of the many difficulties which had to be overcome, as well as the various conditions which had to be complied with, in the construction of this railway. Respecting the mode of constructing the line, there was but one point to which he wished to draw attention, and that was the arched plate flooring. Granting all the advantages claimed for it in the Paper (of strength, of lightness, and of tending to an even distribution of the rolling load), there still remained a grave objection, in his opinion, to the use of steel plates only $\frac{5}{16}$in. in thickness, placed under the conditions which were found at Liverpool. The plates were exposed to the action of the damp sea atmosphere, over the larger part of both their upper and lower surfaces, and also to the effect of rain over about two-thirds of the broad crown of the upper surface. While, owing to the comparatively small height to which the V-channels had been filled up, as well as to plugging up (which often occurred) of the water-outlets from these channels, the upper un-filled portion of the V-channels became in most cases, he had noticed, a receptacle for stagnant water. Under those conditions, he considered it probable that, in the course of a few years, the plates would become pitted and reduced irregularly in thickness. When, also, it was borne in mind that the longitudinal timber sleepers carrying the train-loads rested directly on those arched floor-plates, it would be seen that a state of things fraught with chances of accident, and even with danger, might very possibly arise. He certainly was of opinion that it would have been more economical to have used a somewhat heavier flooring from the commencement.

The comparative tractive effects of electricity and of steam, as shown in Table B of the first Paper, were striking. He considered likewise that the selection in this case of the independent car motor had been a wise one. The driving arrangements had, no doubt, been much simplified by the use, sometimes "in series," and sometimes "in parallel," of the motors; those arrangements were much in advance of the older devices involving chain or tooth gearing. By far, however, the most important electrical question which had been solved by this most instructive enterprise was, in his opinion, the fact that the line was worked practically on what would be termed "low pressure" by the Board of Trade; and without having recourse, despite the length of the line, to those high pressures which constituted a source of danger to life. Furthermore, the mode of working was such that it could be made readily to combine with low-pressure continuous-current arrangements for electric supply for town distribution, adapted to the five-wire arrangement and also to the subdivisions thereof, where in use. This would no doubt be the case more fully in Liverpool, as the demand for the supply increased. The importance of the "low pressure" solution was very considerable, especially in towns where tramways existed; and where these last could be treated electrically on somewhat the same lines as in the present railway—local circumstances, especially as to the conductors, being taken into consideration.

Mr. THOMAS PARKER, in reply to Mr. Aspinall's remarks, observed that the statement as to running at 12 miles per hour, with 16lb. of coal, required to be qualified. The frequent stoppages and accelerations formed a great portion of the work done, and only allowed the trains to attain an average speed of 12 miles per hour. Those accelerations had to be effected in a minimum of time; and, as regards the question of train mileage, there was a considerable mileage travelled by the Liverpool Overhead Railway trains which was not taken into account in the mileage given. The figures given included repairs and renewals to the whole of the haulage plant. The difference between 22½lb. of coal per train mile during the months of April and May, and 16lb. per train mile during August, was accounted for by the larger number of trains in use during the latter month, giving a more even load at the generating station. To compare the trains used on the Metropolitan suburban lines with those of the Overhead Railway, it would be necessary for the former to make the same average speed and the same number of stoppages in an equal distance. He knew of no suburban line which had so high a speed as the Overhead Railway, having regard to the number of stoppages in the distance. The question of end and side-doors was discussed and carefully considered, and he agreed with the opinion of the engineers that the method of receiving and delivering passengers was the quickest and most convenient that could have been adopted. The questions raised by Mr. Crompton as to the efficiency obtained at the generating station would be found answered in Mr. Parker's reply to the discussion. He was unable to give Mr. Nichols an analysis of the figure for working expenses on the Liverpool Overhead Railway, viz., £13,623, which had been taken from the balance-sheet. The Paper did not deal with the traffic and other expenses of the line, but the haulage and the renewal of the haulage plant. In reply to Mr. Mark Robinson, he could only reiterate that the tests were made under the supervision of, and were checked by, the Company's engineers, and were not made for any purpose beyond ascertaining the economical value of the plant for the satisfaction of the representatives of the Overhead Railway Company.

Mr. J. H. GREATHEAD, in reply to the correspondence, observed that Mr. Aspinall seemed to think that the figures given in the

Digitized by Google

Paper were directed to the disparagement of the steam locomotive, and had assumed that the comparisons instituted went further than was actually the case. There was, for instance, no comparison with the working of the locomotives on the main lines of this country; and Mr. Aspinall's suggestion, therefore, that "engine mile" should be used instead of "train mile," had no relevancy; at the same time, whilst he had taken exception to the comparisons instituted with the working of the Elevated Railways in New York, suggesting that they should have been made with railways in this country—overlooking the fact that there did not exist in England a railway worked by steam locomotives so nearly akin to the Liverpool Overhead Railway as were the American lines—namely, having comparatively light trains, stopping at very short intervals (about one-third of a mile), and attaining under these conditions a speed of about 12 miles an hour. Again, in pointing to an English line, and stating that if the authors had been anxious to ascertain what a locomotive dealing with suburban traffic consumed, they should refer to Mr. Stroudley's Paper of ten years ago, presumably Mr. Aspinall had referred to an earlier statement of Mr. Stroudley* in reference to the working of the Brighton line between Victoria and London Bridge, because Mr. Stroudley's Paper of 1884 did not deal with suburban traffic. Mr. F. Fox and he had considered that case because it did comply to a certain extent with some of the conditions—the trains and locomotives were comparatively light, and the service was somewhat of the same character; but, upon looking closely into the facts, it became clear that the main governing condition, namely, the distance between the stations, was widely different, being nearly a mile instead of one-third of a mile. As Mr. Aspinall, however, had laid special stress upon this matter, because, as he had stated, if the comparison was to be made about fuel consumption, "it should be made with English railways, and not with American, where but little care was taken about economy in fuel," it might be interesting to institute a comparison based upon the figures given by Mr. Stroudley, and estimating the effect of the more frequent stoppages of the trains. The Brighton locomotives described by Mr. Stroudley weighed 24 tons, all on six-coupled driving wheels 4ft. in diameter, having cylinders 13in. in diameter, and a 20in. stroke, and steam pressure of 140lb. per square inch; the average weight of the trains was stated to be 59 tons, the average speed 15 miles an hour, the average stoppages about 1,500 yards apart, and the coal consumed was given at 21·63lb. per mile. Calculating the average power exerted by the locomotives, it would appear that they consumed about 3·9lb. of coal per indicated horse-power per hour; and that in order to maintain a speed of about 12 miles an hour (including stoppages) with the same trains, on a line having stations one-third of a mile apart, their consumption at the same rate would be about 60lb. per mile, instead of 21·6lb.—the average weight of a train, including locomotive and passengers, being taken at 90 tons—as compared with the 16lb. of coal per mile for the 38-ton trains at Liverpool; the coal used in the steam locomotives being of a superior character, and costing considerably more than the class of coal used at Liverpool. To complete the comparison it might be added that the tractive force per ton of train (75lb.) was very little more than that given in Table B for the District Railway locomotives, though the maximum tractive force per ton of locomotive (328lb.) was considerably in excess of the District engines, but was still less than half that of the electric motors at Liverpool. The comparison suggested by Mr. Aspinall was, therefore, on the whole not less favourable to electric traction at Liverpool than the comparison made in the Paper with the American lines. With regard to the suggestion that the working expense at Liverpool did not include a proper provision for renewal of plant, which Mr. Aspinall had taken from the Liverpool Overhead Railway Company's accounts as having cost £73,744, it was right to state that the figure given in the amounts included not only the locomotive plant, but also the carriages, the buildings, and the foundations at the generating station. The Company's accounts did include a proper provision for the renewal of plant, and that provision, added to the actual cost of working since it had been taken over by the Company, would still leave the total locomotive expenses at less than 4d. per train mile. As regarded the design of the carriages, Mr. Aspinall, when he expressed surprise that they had not been constructed similar to those in use on the elevated railways of New York, had no doubt overlooked the fact that in Liverpool two classes of passengers had to be dealt with; and he appeared also not to have observed that the Liverpool carriages did possess central passages. The Liverpool carriages had been found in actual working to be very convenient, and the side doors did not interfere with the passengers on the platforms.

It was satisfactory to find that Mr. Lincoln Moss, who conducted the experiments on the Manhattan Railway referred to in the Paper, was of opinion that, as regarded motive power, it would have been a mistake to have equipped the Liverpool line with steam locomotives, though it was difficult to understand why he should have though it unfair to compare the cost of working the Liverpool line with that of the New York lines, on account of the greater number of trains running upon the latter, because the effect of a more frequent service upon electrically-worked lines was to reduce materially the cost of working. The Paper defined clearly the difference between the weights of trains on the two lines. Allusion had been made by Mr. Nichols to the Liverpool Overhead Railway as the first permanent elevated railway worked by electricity. As a matter of fact, it is the first elevated railway so worked, having been established before the Intermural Railway at Chicago, to which Mr. Nichols had referred. It did not seem to be necessary to follow Mr. Nichols' comparisons of the cost of working the Liverpool, Manhattan and Brooklyn railways; because, without having the details of prices and cost, and the amount of labour, upon which his figures were based, it was impossible to form any estimate as to actual results. It was, however, satisfactory to find that, notwithstanding that the cost of wages and coal had been reduced by one half on the American lines, the cost per ton mile on the Liverpool line with its comparatively short train mileage was still considerably below that of the American lines. As to the estimates of percentage of working expenses to gross earnings in the several cases, such comparisons, though convenient commercially, in comparing like with like, were not reliable; because they depended on the amount of traffic and earnings, and were therefore not indicative of economy or otherwise in the working. The Paper dealt only with the locomotive expenses, and not with the total expenses of the railway—a fact which Mr. Nichols did not appear to have appreciated. It was not contended in the Paper, as Dr. Preller had suggested, that motor-carriages were better than separate locomotives under all conditions; on the contrary, it was shown that different cases required different treatment. Into Dr. Preller's comparison of the total cost of working the Liverpool Railway with that of working the City and South London line, it did not seem to be necessary to enter; the conditions being widely different, and the ratio of expenses to gross receipts not affording a satisfactory gauge. The locomotive expenses of Continental tramways worked by electricity did not appear to be comparable with those of the Overhead Railway, in the absence of fuller details of the tramway working, weights drawn, mileage, and so on.

In reference to the few remarks that had been made upon the structure of the railways, Mr. Shoolbred's criticism upon the arch-plate flooring was directed against the thickness of the plates—namely, $\frac{3}{16}$in.—which he considered too thin for safety and economy, having regard to the possible effect of the damp sea atmosphere and rain. That, however, was entirely a matter of maintenance; the plates, if properly coated, would last indefinitely; if they were twice as thick, and were neglected, they would not last very long. Some of them which had been fixed for about four years showed no signs of deterioration.

With regard to the strength of the decking referred to by Mr. Fitzmaurice, it might be stated that the heaviest weight on an axle was 6·6 tons, or 13·2 tons for the two roads; while the tests showed that there was no sensible deflection with a load of 30 tons, and no permanent deflection with 105 tons distributed on three arches of the decking.

THE ELECTRIC BRAKE IN PRACTICE.*

BY ELMER A. SPERRY.

Enterprise in the United States for the public convenience of her citizens is truly phenomenal, and reaches its highest expression in conveniences for travel. Vast skill and almost untold resources have been devoted to perfecting means for overcoming inertia, and quickly accelerating cars and trains, which are ever increasing as to their weight and capacity. It is proverbial that while these advancements have been going forward, comparatively no attention has been paid to the mechanism for retarding, and quickly, but smoothly, bringing the cars and trains to a stop.

As the practice of the steam railroad engineer as to road beds, speeds and weights are gradually approached, his experience in the solution of this most important problem of braking should be studied with care. In so doing, however, the features wherein the street car problem is differentiated from the steam road problem should be kept prominently in mind. We must remember that the locomotive engineer is provided with a complete, expensive and somewhat intricate apparatus with which to de-energise his train. The periods of its application are comparatively infrequent, and as to personal capabilities, he is schooled and trained for years before ever being allowed to touch either the throttle or the air valve. While working, his pressure gauges allow him to adjust the brake application to a nicety. Moreover, the time

* Abstract of a Paper presented at the meeting of the American Institute of Electrical Engineers, September 19th.

Digitized by Google

allowed for the total retardation, and final stopping of his train is usually very long as compared with that allowed in street railway practice.

Of the two, the street railway problem is the more exacting, and in the hands of far less experienced operators; and yet we are told that the mechanism involved in its solution must bear only a small ratio to the cost of the total equipment. Owing to the recently-developed relation between effective braking and the accident and damage account, the purchaser will be spurred on to careful investigation as to the brake applied to his cars, and will be willing to spend sufficient time and money to effectually control retarding, as well as accelerating the car. To be sure, as little expense should be incurred here as possible, but enough to fully meet the requirements. Especially is this true, now that ample power for applying the heaviest brakes is at hand, and even if used in a wasteful and extravagant manner in the largest amount possible, is entirely without cost, and its means of control already at hand. The importance of this proposition should at once command the attention of all, and commend the problem as such to the engineer.

Examination of accounts of the electric street railway companies of our large cities reveals the fact that the item of damage, already very great, is one of growing importance. Investigation of the circumstances and detailed statements of numerous items taken at random from the damage account, point at once and in no uncertain way to the inefficiency of the present hand brake. In many instances, could the car or train have been stopped within a comparatively short distance, the accident and resultant damages would have been entirely averted. The first investigation led to others with the same result, and in consequence the writer is prepared to show that nearly 85 per cent. of the accidents directly occurring, are due to the inefficient operation of brakes. The growing frequency of accidents, and the constantly increasing demands of the public for damages, are indications that have not been made to impress the mind of the engineer, or I am sure adequate means would have been forthcoming for the correction of so grave a fault inherent in all the present systems of power-operated street cars. Some of our municipal authorities are taking action with reference to the increasing frequency and severity of accidents, and although no thorough scientific investigation of the matter has been published, yet it is a startling fact that with the present hand brake no electric or other equipment to-day stands provided with anything in the line of an emergency brake. In so grave and urgent a case, what can be done in the line of remedy? The question naturally arises: Will any system of braking worked upon or in connection with the ordinary wheel of a vehicle be sufficient for the stop required? What is the maximum efficiency obtainable by the brake working through the wheels? Is it sufficient to arrest the car before accident in case of emergency? Can it be made in any event a sufficient accident preventer? The popular notion that most accidents are due to brake failure is true; but in a way that is little understood, the failure being one of degree. It may not be known that under proper and standard conditions any car or train may be brought from a speed of 10 miles an hour to absolute rest inside of 10ft. It is not generally appreciated that the wheel brake has ample capacity to accomplish this. The former investigations of the writer with reference to adhesion under conditions of acceleration and retardation, climbing and descending hills, afford ample proof that the rail adhesion through the wheels gives the wheel brake more than capacity sufficient to accomplish this result. For instance, assuming any weight and load, say 17,000lb., the stored up energy, 64,426 ft. lb. can with ease be dissipated within 20ft. for the ordinary equipment, and less than half of this distance, or a little over 9ft., under conditions of coupled drivers, or if the wheels are compelled to revolve in unison. This latter consideration will be seen to have quite an unexpected as well as pertinent relation to the problem. It will be seen by a glance at the figures that the centre of gravity of the mass is far above the wheel contact with the rail. The retarding effect takes place on the base line in a plane below that of the centre of gravity, really the farthest projection downward of the mass as a whole. A sudden stop operating on this base line tends to pitch the upper portion forward, bringing nearly all of the weight, and with it the retarding capacity, upon the front pair of wheels. The brakes in the rear pair in the ordinary equipment will have but little effect; if, however, by any practicable method they are coupled to the forward drivers, the brakes on this rear pair still remain active and of full effect. This is true even if the back pair should be lifted clear of the track. With increased weight upon the forward drivers comes ample increased adhesion, thus preserving the full tractive effort of the total weight intact for purposes of stop, which is impossible in the ordinary equipment. These effects are all aggravated in case of short wheel base. The present tendency toward a longer wheel base is a step decidedly in the right direction, and should be encouraged. The effect of shifting the load in reference to the axles will be especially noticed in descending hills, as shown in Fig. 1, where the momentum of the rapidly retarded mass tends to shift the load centres still further forward, in some cases almost wholly on to the front drivers. It will be seen to have a greater effect than in *ascending* grades, where in stopping, the inertia tends to correct the position of the shifted load; whereas going down, in stopping, the momentum as stated tends to still further aggravate the condition. The practical effect of this may be seen whenever an ordinary street car mounted upon springs of fair resilience is quickly stopped. The car will be seen to suddenly right itself, having been pitched forward in the process of stopping (*see* Fig. 2), the front springs being depressed and the rear springs extended. These considerations all go to show in a new light the advantages to be derived from coupled drivers for general street railway service.

Bearing these facts in mind, let us turn for an instant to the ordinary hand brake. The ratio in the brake levers will be found in the modern trucks to be anywhere from 6 to 11½, averaging about 8½ to 1. The lever arm of the brake staff will be found to be anywhere from 6in. to 13in. Assuming 11in. as the average, the radius from the centre of the brake chain to the centre of the brake staff will be 1¾in., giving thus 6·28 to 1, or a total leverage of 53·4 to 1 from the operating handle to the brake beam. Two elements now have to be assumed. First, the friction coefficient of the brake shoes acting upon chilled wheels. Second, the power upon the brake staff. The writer has endeavoured to cover both of these unknown quantities by actual experiment, giving the results in the tables. Table I. was taken by a dynamometer being fastened directly to the brake staff handle in line of the pull of the motorman, a cast-iron brake wheel 16in. diameter from centre to centre of a 1¼in. rim bearing

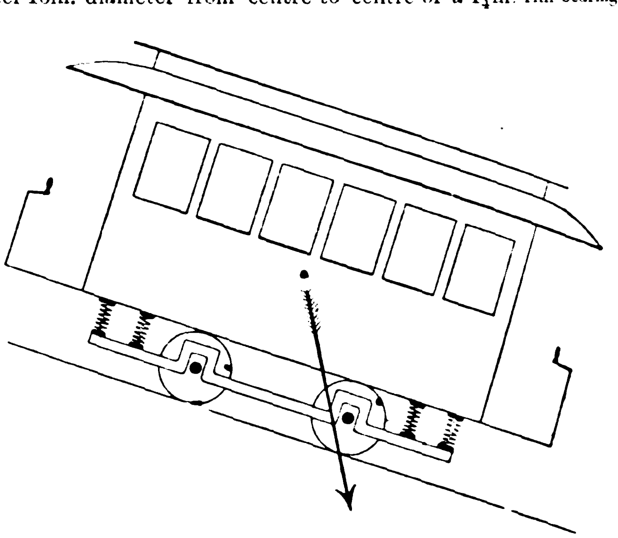

Fig. 1.

the handle. A number of experienced motormen were invited to test their strength upon this handle, and careful readings were taken. It was noticed that the right arm of the more experienced motormen was much more developed than the left, a fact which I think has been pointed out before. The extent of this development in the forearm is certainly quite marked, showing that the gripping muscles and weight of the body are the elements brought most into play.

Columns 1 and 2 indicate respectively the number of the motorman and his weight.

Column 3 indicates the greatest possible steady pull with the right hand on the handle, bringing into play all possible weight of the body.

Column 4 indicates the same conditions as column 3, the motorman in this case grasping the hand-wheel with both hands, some motormen using gloves to prevent their hands slipping. None of the men could maintain these values for more than half a second.

In column 5 is indicated an "emergency stop." The motormen were told to "break the machine" if possible. In this test the body was braced, sometimes with the knee against the dasher rail, the needle registering the highest jerk usually given with a sudden lunge of the body.

It will be seen that the power applied by the steady pull of the average motorman is about 131·7, and can be made to run up in case both hands and the weight of the body are used, to about 224 average, but this value cannot be maintained. The average values of column 5 cannot be used in these calculations, for the reason that although they show the pressure it is possible to reach by jerking upon the hand-wheel, these pressures cannot be maintained, and therefore cannot be depended upon for braking effect. The tests show that the full power that can be maintained upon the brake lever for a sufficient length of time for the purposes in hand, does not exceed an average of 180lb.

Table II. was obtained as shown in Fig. 3. A brake shoe that had been run in service about three or four days was taken with the axle carrying its co-operating wheel lifted out of the truck and placed between the centres of a lathe, the load upon the brake shoe accurately measured, and the shoe held from movement around the wheel by a dynamometer. Every precaution was taken to avoid handling the periphery of the wheel or the face of the brake shoe, and even the dust was left upon it so as to conform as nearly as possible to the normal conditions of practice.

Tracing our 180lb. application to the brake beam, with allowance for loss by friction, we have 3,840lb. applied to each of the two shoes, which upon the chilled surfaces are found under ordinary circumstances by Table II. to give a coefficient of about 12 per cent. This would give a retarding effect of 460lb., which is less than one-third that easily obtainable were the power needful for its application at hand. The coefficient under these conditions would have been about 37 per cent. to realise anything like the total value of the retarding effect of the wheel. This, under condition of chilled and glazed surface, is entirely out of the question, showing at once the necessity of power in the application of brakes, if anything like their full value and use is to be obtained. This is also amply borne out in practice, as those who have tested this point well know that under ordinary conditions it is next to impossible to slip the wheels of a motor car by the hand brake.

In the electric brake, on the other hand, the fact that the truck parts are not bound up and locked into a solid mass by the enormous pressure of the heavy brake levers and shoes is found to prevent racking and straining the truck, as well as jumping the track and curves when the brakes are set. The axles and truck parts are perfectly free for easy and normal movement even when the brake is exerting its full power. Great reduction of wear at the pedestal journals is also found, owing to entire absence of all of the usual heavy pressures of the brake shoes. We can all see that by applying adequate power and control to the wheel brake, this element of the equipment may be raised to the position of an indispensable safeguard, the value of which can only be appreciated as its hitherto undeveloped resources are brought out, demonstrated, and rendered simple and easy of application and control. In practice the greatest necessity for maximum brake application exists at the higher speeds. From Table II., it will be noticed that at just this point the failure is greatest, the coefficients being least; increasing as the speeds decrease. This has always constituted the one grave fault of the air brake in railway service. The intensity of its application should be greatest when the speed is greatest, and decrease as the speed drops off. As will be shown farther on, this point has been fully covered in the electric brake, which is the first time that the varying application has even been embodied in practice, and especially in such a manner as to perform its important function automatically.

A plan, especially one pertaining to electrical matters, after having been proven mathematically to be feasible, is far from being realised. Many are the practical difficulties to be surmounted before a thoroughly commercial, or anything like a standard, apparatus has been produced. Especially is this true in the electrical field. Many subtle influences and energies are at work which well

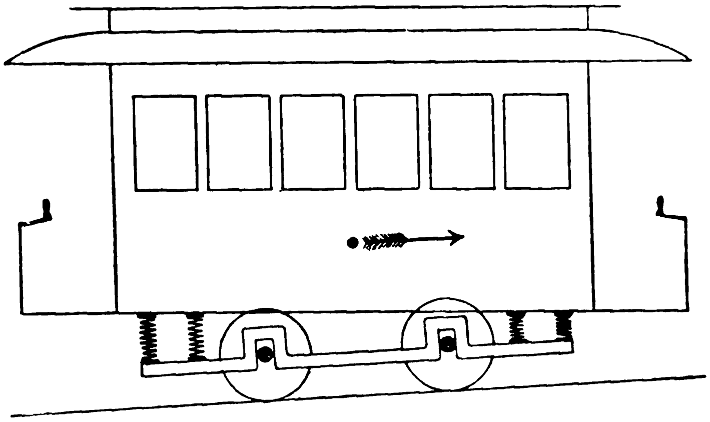

Fig. 2.

nigh overwhelm the experimenter. In a new field but few precedents are at hand, and these are apt to be extremely unreliable, and in the nature of a blind leader of the blind. The practical application of the electric brake, although probably no exception to the general rule, amply illustrates the wide distance to be spanned between the conception of the idea and the commercial apparatus itself. For years the writer has believed that electricity was vastly preferable to any other force for the application and control of brakes. Working first on the solution of the continuous-brake problem for railway trains, he built his first electric brake apparatus in '82, and has studied and experimented on the problem in its various phases almost continuously since that date, with more or less encouragement in the line of substantial progress. As to its application to electric cars, the apparatus was successfully applied on some double truck cars in Illinois, one of these cars weighing as

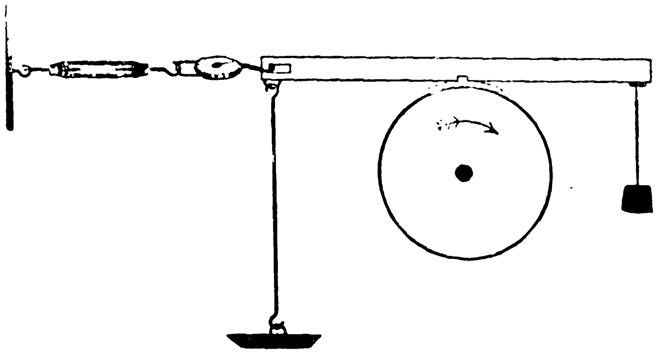

Fig. 3.

much as 12 tons. The first equipment was constructed some five years since. This apparatus has been constantly undergoing alterations and been experimented with, until for the past 18 months a constantly increasing number of electric cars, equipped with it, have been in regular service, some of these running, with change of motormen on each of 13 daily trips, the same motorman having the car once in about three days, making it impossible for the men to become familiar with the operation of the brake. During this time one car has made upwards of 70,000 miles, hauling a trailer about 48,000 miles, during some special weeks of test, making from 178 to 220 miles daily. It is only under such rigorous conditions of actual operation that rapid progress can be made in reduction to practice. All machinery or apparatus must pass this ordeal successfully before it can be brought into thorough commercial shape.

At the mention of electric brakes the engineer at once admits that they should be entirely feasible, and usually adds that there

Digitized by Google

is plenty of electrical energy at hand from the central station to retard and control as well as to propel the car. This, however, is not the method undertaken by the writer. To employ the central station current for operating the brakes would be to limit very materially their usefulness and certainty of operation. The braking current, although used at comparatively infrequent intervals, and then only for a short period, should for this reason be absolutely certain and unfailing in its action, and not subject to any "heart failure" of the central station, or sudden cessation caused by the opening of the circuit breakers, the interruption of the line, the flying off of the trolley, failure of the fuse, or failure at other more or less vulnerable points. The electric brake under discussion has been operated over a year on equipment upon different roads, from electricity generated independently of the trolley connection, the braking current not being derived from the central station but produced by the power of the moving car, which power it is desired to get rid of, or destroy. The brake thus operates equally well with the trolley off, and, as will be understood from the following description, the trolley current has nothing at all to do with the car while the brake is being operated, except possibly to maintain the light circuit. The electric brake at the same time is entirely independent of the hand brakes, which may or may not be present upon the equipment. The braking action being altogether independent of the ordinary brake shoes, it is not found necessary to employ them in connection with the electric brake, although in the earlier forms they were used, and in the case of trail cars, especially in heavy service and on grades, some engineers prefer to use them at the present time. The current employed by the writer for operating the brakes is developed by automatically turning the motor or motors into generators. As these are driven forward by the moving car they develop current which is controlled as to intensity by the starting rheostat of the car. The braking current is thus produced at the expense of the mechanical energy stored up in the moving car, which, being consumed, causes a retardation and final stopping of the mass as a whole. The current so generated may be furthermore led through a brake magnet, as above seen, to apply the brake shoes; it may arrest the motion of

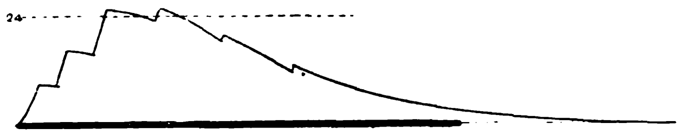

FIG. 4.

the car direct by magnetic adhesion, or develop heavy retarding currents in the moving metallic mass by magneto-induction. When an active local circuit is used the latter method is usually employed, for reasons which will be made more apparent.

In developing this system, the point which seemed fraught with the most difficulty, and which has finally received the simplest solution of any in connection with the problem, was that of obtaining always and with absolute certainty sufficient current at the lowest speeds without the aid of the trolley current. Teaser coils were at intervals resorted to, maintaining connection with the trolley circuit. "Artificial teasers" were also used, being a device by means of which the trolley circuit was entirely done away with, and which worked well. Observations made from time to time in connection with these experiments led to an exhaustive investigation of residual magnetism, in consequence of which structural means were adopted to utilise to the full the residual magnetism of the motor. This supply is constantly being renewed with every energising of the car. This method was found to be the simplest as well as the most effective. The connections, and, in fact, the whole arrangement of the electric brake upon the car, is extremely simple. This is shown by the fact that only one small extra wire needs to be run to the controller in addition to the ordinary wiring of the standard equipment without the electric brake. The certainty of operation is evinced by the fact that at present writing over 150 of the equipments have been placed, which are making upwards of 10,000 miles daily in regular service. Early in the experimentation a phenomenon was observed in reference to the persistence of the current even after the motor had stopped. This is due to the slow action of the decreasing magnetisation, taken together with the reaction or self-induction effect of the fields, and any brake coil or coils that may be in the circuit. The movement of the magnetic lines, which persist after, and in fact long after the motion of the motor has ceased, generates potential. In many instances it is possible to draw an arc from the rupture of the brake circuit one second after the motion has ceased, showing the presence of current in the local circuit. Fig. 4 has been developed from the average stop to show the curve of current in reference to the motion, the black lines indicating the period of motion during the application of the brake, and the curve indicating the current intensity and its duration. The current flowing after motion ceases, though small, is found exceedingly useful in holding the car from starting itself, even on quite a heavy grade, as only a small quantity of energy added to the already great friction of quiescence will prevent the car from starting. This persistency of current is also found useful to destroy the magnetism of the brake magnet, in case it is desired to suddenly move the car forward again. The tendency on the part of the windings at the moment of rupture to generate an opposing E.M.F. tends to suddenly free the magnet from its face, a purely accidental feature, which is of great value and utility in this connection. The wonderful energy of the withdrawal of the lines of force being in its manifestations a phenomenon of magnetic viscosity, is illustrated by the following fact: With a perfectly dry track a great force is required to shear the adhesion and start the wheels slipping. A car going down a grade under these conditions where no brake magnets are present, will, with a sudden application of the electric brake, generate sufficient current to not only arrest the motion of the wheels but start them going in the opposite direction; the reverse motion being maintained through an interval truly remarkable, in some instances running as high as one and one-half seconds. It will be borne in mind that all the above phenomena are entirely independent of the central station current, the trolley connection having been severed before the brake is applied.

(*To be concluded.*)

THE CLARK CELL WHEN PRODUCING A CURRENT.*

BY S. SKINNER, M.A.

The electromotive force of the Clark cell when not producing any current has been frequently determined, and has been found to be of so constant a value that it is now used as a standard. In the following an account is given of a series of experiments made on cells when producing currents, with the view of ascertaining (1) how far the total E.M.F. round the circuit differs from that of the open cell, and (2) how this new value for the E.M.F. changes when the current is maintained. If these quantities can be accurately measured, it follows that a cell might be used for producing currents of known value.

The experiments were made on three cells, all much larger than the ordinary Board of Trade pattern of Clark cell. Cell B was made July, 1891, and the area of its exposed zinc surface is approximately 14·4 square centimetres. Cell L, made November, 1892, is a much larger cell, fitted up in a cylindrical jar 22cm. high and 13cm. in diameter. The zinc plate exposes an area of about 95 square centimetres. Cell N, made July, 1893, is intermediate in size, and exposes about 29cm. of zinc surface. In all three cells the zinc plate, a piece of common zinc sheet, is placed horizontally, and they have the same E.M.F. within two parts in 5,000.

The external resistance used consisted of thick wire coils or of a special wire resistance immersed in a large tank of paraffin oil.

As an instance of what happens when the poles of a cell are united, the author describes the following experiment: On July 25th the cell L had an E.M.F., with its poles open, represented by 5,009 on the compensator. The poles were then joined by a resistance of 1,000 legal ohms, and their potential difference, taken as quickly as possible, was then rather more than 4,983 and rather less than 4,984. Then a resistance of 500 legal ohms was substituted for the 1,000; the potential difference fell to 4,959. Next, with 200 legal ohms the potential difference was 4,885. Lastly, the poles were opened, and the E.M.F. of the cell was found to be 5,009. It is seen from these numbers that the cell recovered its E.M.F. entirely after the various operations, and this is a typical instance of the behaviour of the cells.

The important determination of the resistance of the cells was made by the method of opposition, and by the use of an alternating current. By opposing any two of the cells, the resulting E.M.F. was so small that, making them an arm in a Wheatstone arrangement, there was no deflection in the bridge galvanometer. The bridge was fed with an alternating intermittent current by means of the commutator used by Mr. T. C. Fitzpatrick in his electrolytic measurements, B.A. report, 1886. The errors to which this method of measuring battery resistance is liable are two: first, from self-induction, and second, from polarisation at the electrodes. The only conductor containing self-induction of any magnitude is the galvanometer coil, and as the method is a zero method this does not matter. The second error is eliminated by using an alternating current. However, following Fitzpatrick's method, tests were especially made for polarisation by varying the ratio of the arms and by varying the speed of the commutator.

* Abstract of Paper read before the Physical Society.

By means of the method described by the authors and Mr. Glazebrook (*Phil. Trans.*, 1892), the results in the following table were obtained. The units of E.M.F. are appropriately $\frac{1 \cdot 4}{5000}$ volts.

B. „ 25 ...	5007	4971·5	4938·5	4841	......

Using, then, the equation

$$e = \frac{R+r}{r} \times \text{potential difference},$$

where e is the value of the E.M.F. required to produce the observed current, R is the internal and P the external resistance, values of e are deduced, from which are obtained the values for

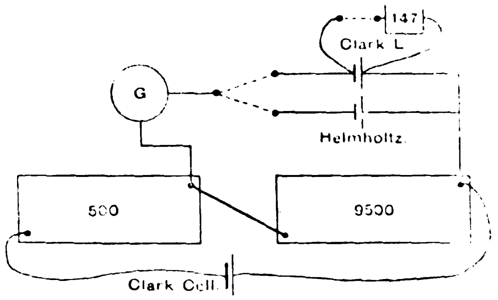

Fig. 1.

$E-e$, the E.M.F. of polarisation being $-(E-e)$. It will be observed that for a given cell the E.M.F. of polarisation is directly proportional to the current density.

Table II.

——	$E-e$ for 0·0014 ampere.	$E-e$ for 0·0028 ampere.	$E-e$ for 0·007 ampere.	$E-e$ for 0·01 ampere.

N.	18·5	36·5	.. ...	......
B.	4	7	17	... ..

The experiments to be described in this section show how the potential difference varies when the cell is allowed to produce a current for some time. For these experiments the standard of refer-

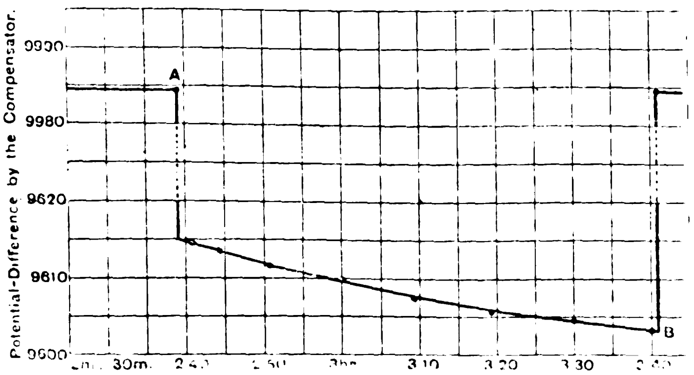

Fig. 2.—January 16, 1893. Temperature 12°.—At A, the Clark cell L was short-circuited by 147 ohms. At B, the circuit was broken.

$$\text{Unit of E.M.F.} = \frac{\text{Clark}}{10{,}000}.$$

ence was a set of Helmholtz cells described in the Paper quoted above; they were immersed in a tank of paraffin oil. On January 17th they were submitted to a very rigorous test for constancy, extending over four hours, a Clark cell being the standard. It is not necessary to say anything further about them.

The arrangement used in the experiments is illustrated in the accompanying diagram (Fig. 1), which clearly explains itself.

A set of observations is given in the accompanying diagram (Fig. 2).

The four experiments made gave an average fall of seven units in the hour, and from the table we have the polarisation on immediately making contact equal to 29 units $\left(\frac{\text{Clark}}{5{,}000}\right)$, or 58 of our present units. The polarisation, or $-(E-e)$, for a current density of $\frac{0 \cdot 01 \text{ ampere}}{100 \text{cm.}^2}$ for cell L may at any time be expressed approximately by $-(58+7t)$, where t is the time in hours, and the unit of E.M.F. is $\frac{\text{Clark}}{10{,}000}$. Expressed in volts this is—$(0 \cdot 00854 + 0 \cdot 001\,t)$. It is deduced from experiments on cell L, and only indicates the general order of magnitude of the effect with the other cells.

Conclusion.

Throughout the calculations it has been assumed that the total E.M.F. round the circuit is equal to that of the cell at rest; and therefore that the E.M.F. overcoming polarisation can be obtained by subtracting from the E.M.F. of the cells at rest the observed current. With the exception of small Peltier effects, I know of nothing against this assumption.

The results of the experiments are:—

(*a*) The E.M.F. of polarisation varies directly with the current-density in a particular cell.

(*b*) The E.M.F. of polarisation slowly increases when the current is maintained.

From the magnitudes of the quantities found in these experiments, it follows that small currents of approximately known value can be obtained by the use of large Clark cells of small internal resistance, which may be neglected in comparison with the large external resistance. The experiments show that the large cell L when producing 0·01 ampere was not at all disturbed. This corresponds to a current density $\frac{0 \cdot 01 \text{ ampere}}{95 \text{ (centim.)}^2}$. Now in a Board of Trade pattern Clark cell there is generally an exposed area of zinc equal to 2 (centim.)^2, and as the current taken is never greater than $\frac{1 \cdot 43}{10{,}000}$, a 10,000 ohm coil being used in series with it, it follows that the current density with this value of current is very much below that which has been found to be safe in these experiments.

In the experiments of Threlfall the sign of the term depending on time was found to be negative. In some of my earlier experiments it appeared to be negative; but this was traced to irregularity in the working of the compensator, and the effect has always been positive since the Clark cells have been used in the place of Leclanché.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The 1894 Edition of "The Electrician" Electrical Trades' Directory and Handbook contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook, from October 1st, is 5s. post free; abroad 5s. 6d. *The 1895 edition is in active preparation.*

"Electric Motive Power."—A new work, by Mr. Albion T. Snell, with this title, will be ready in October. It will contain the latest information respecting the application of electric energy to mining purposes, in which the author has had much experience. The book is well printed, on good paper, and will contain nearly 250 illustrations, a large proportion of which have been specially made for the book. The price is 10s. 6d., post free 11s. (abroad 11s. 6d.). Orders can now be sent in.

"The Work of Hertz."—The lecture delivered by Dr. O. J. Lodge at the Royal Institution on June 1st is reprinted with corrections and additions, and many original illustrations, price 2s. 6d. net.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., will be ready early in October, handsomely bound, full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"Electrical Engineering Formulæ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"Electromagnetic Theory," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"Drum Armatures and Commutators."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

Digitized by Google

TENDERS INVITED.—The Directors of the Lancashire and Yorkshire Railway invite tenders for the supply of the Company's ordinary requirements of various articles during the twelve months ending October 31, 1895. The list is set out in our advertisement columns, and further particulars and forms of tender can be obtained at the Stores Department, Osborne-street, Manchester, where samples can also be seen. Tenders have to be in by 10 a.m. on October 8th.

——— Mr. John Annan, manager for the liquidator in J. W. Hobbs and Co. (Limited), invites tenders for the supply and erection of boiler house plant, engine house plant, switchboard, instruments, &c., for the electric light and power installation at the large block of hotel buildings now erecting on the Salisbury Estate, Victoria Embankment, and Strand, London, W.C. Plans and specification, &c., can be obtained of Mr. R. Hammond, consulting engineer, Ormonde House, Great Trinity-lane, E.C., on and after October 5th; and tenders must be sent in before Friday, October 26th. Further particulars are given in our advertisement columns.

——— Persons willing to tender for supplying, fixing, and maintaining fire calls and telephones for the Stroud Volunteer and Local Board Fire Brigades should send tenders by October 2nd to the clerk to the Stroud Local Board

TENDERS ACCEPTED.—The contract for the cables for the extension of the electric light by the Glasgow Corporation, amounting to about £4,000, has been secured by W. T. Henley's Telegraph Works Company (Limited).

——— The Cardiff Corporation have accepted the tender of Messrs. Fergusson and Co., Cardiff, for wiring the Town Hall and Market-place, at a cost of £523. 10s.

SALE BY AUCTION.—Messrs. E. and H. Lumley announce the sale by auction, at the Mart, Tokenhouse-yard, London, E.C., of the lease of valuable premises in Hanover-square, London, W., between Regent-street and Bond-street, specially suitable for a business requiring spacious show rooms, with workshops and other accommodation attached. Further particulars are given in our advertisement columns. The sale will take place on Tuesday next, October 2nd, at 2 o'clock.

APPOINTMENTS.—Our note of last week respecting Mr. J. B. Mitchell should have stated that he had been appointed electrical engineer to the Dewsbury Corporation.

DISSOLUTIONS OF PARTNERSHIP.—The partnership existing between H. Coltman and Sons, of Loughborough, mechanical engineers, boilermakers, &c., has been dissolved, Mr. H. Coltman retiring.

——— The Mossley Rubber Company, Mossley, Chester, india rubber manufacturers, has been dissolved. Debts will be paid by Mr. E. Davis, who continues the business.

PERSONAL.—Mr. S. A. Edwards, metal merchant and agent, of 30, Easy-row, Birmingham, has taken into partnership Mr. W. H. Hatton, of Victoria-buildings, Birmingham, and the firm will in future trade under the name of S. A. Edwards and Co.

AMALGAMATION.—The Swiss Metallurgical Company and the Company for the Manufacture of Aluminium have been amalgamated, with, it is stated, a capital of 11,000,000 francs.

BANKRUPTCY.—Mr. Henry W. Figg, of 37, Upper Thames-street, has been appointed trustee of the estate of Messrs. Young and Buss (see *The Electrician*, September 14th). At the first meeting of creditors, last week, the liabilities were estimated at from £5,000 to £6,000, and the assets at about £4,900.

BANKRUPTCY STATISTICS.—The eleventh annual report of the working of the Bankruptcy Act, 1883, is just issued. The receipts for the past year amount to £153,420, and the expenditure to £167,019. The receipts include £72,159 for stamps and £60,750 for fees. The expenditure shows an increase over the previous year; but there is still a net surplus, for the ten years during which the Act has been in operation, of £145,471. It is pointed out that a saving has been effected to the exchequer during this period of £25,000 as compared with the previously existing system, and this result has been obtained concurrently with the reduction in the number and amount of insolvencies and in the cost and duration of the bankruptcy proceedings, an increase in the proportion of assets distributed amongst creditors, and a much stricter enforcement of the penal provisions of bankruptcy law. Additional security against fraudulent bankruptcy is given under the present law by the public investigation into the conduct of the debtor and the causes of his failure. The average cost of administration of estates by official receivers under the present Act during the past three years was 21·01 per cent. of the gross assets, as compared with 43·95 per cent. in the case of similar failures where the estates were administered by non-official trustees under the Act of 1869. It is remarked that such a large reduction in the cost of bankruptcy administration is an undoubted public advantage. During the year under review failures representing £7,492,367 were chronicled, the assets reaching £2,818,448, and an estimated loss to creditors of £5,588,936. This is a decrease in the estimated loss in comparison with the previous year of £1,102,705. In addition there was, under the Deeds of Arrangement Act of 1887, an estimated loss to creditors of £5,280,165, which shows a substantial advance on the figures of the previous years.

LESLIE v. ROGERS.—In the City of London Court, Mr. William Hicks, solicitor, appeared for the plaintiff, the Receiver of Woodhouse and Rawson (Limited), Queen Victoria-street, who sought to recover the sum of £12. 18s. 6d. for goods supplied to the defendants, Messrs. Arthur and J. W. Rogers, trading as the Mechanical Engineering Company, of Saffron-hill, London. The defendants disputed some of the items of the account, because some of the goods were ordered by their manager for himself. In the end the Court found for the plaintiff for the sum of £9. 12s. 8d.

TRADE MARKS IN GERMANY.—In reference to a note which appeared in our issue of the 15th inst., the Secretary of the London Chamber of Commerce points out that the provisions of the law respecting the protection of trade marks (November, 1874) will continue to apply to marks entered in pursuance of that law in the register of marks until October 1, 1898. The protection afforded to merchandise marks under this older law expires simultaneously with the entry in the new register, which comes into force next month, or, failing this, with the term ending on October 1, 1898.

MESSRS. CHARLES CHURCHILL AND CO.—This firm have been appointed agents for Great Britain of the Brown and Sharpe Manufacturing Company, of Providence, Rhode Island, U.S.A.

"WEBBER" APEX CONNECTOR.—We are informed by Major-Gen. Webber that the ordinary means of using a plug attached to the wire and inserting it in the socket affixed to this apparatus was discarded by him some two or three years ago, and the obvious alternative of reversing the ordinary arrangement so that no "live ends" should be exposed to accidental short-circuiting, was registered by him in January, 1893. He has adapted such a socket and connection to the apex of a conical lamp shade for a table standard. The standard and base need not be fitted with lamp holder or wires; all the electric part of the fitting is attached to the shade.

EPSTEIN ACCUMULATORS.—In reference to the statement made in our Trade Notes last week, referring to the manufacture of Epstein accumulators by a leading firm of electrical engineers, under the supervision of the Epstein Company, we are requested to state that this is inaccurate. The Epstein batteries are being made exclusively by the Company at their own works at West Kensington.

OIL ENGINES.—We have received circular particulars of the Imperial oil engine made by the Imperial Gas and Oil Engine Company. The circular gives particulars of horizontal, portable, and marine engines made on this principle, for which the advantages of simplicity and economy are claimed.

STEAM TRAPS.—Messrs. Alex. Turnbull and Co., of Glasgow, send illustrated particulars of their patent suspension and compression spring balance steam traps, as well as of the multiple expansion steam trap made by them, for which many advantages are claimed. These traps are direct acting, and are of simple construction. They are made without cranks, levers, balls, sliding sleeve, or shutting valves. The spring of the float vessel is made of special metal, which is practically non-corrosive. The multiple expansion steam trap consists of a series of rods connected by plates and suspended loosely by a regulating screw, so that the valve which is formed on the bottom end of the centre rod is just touching the seat when there is very little water in the trap. Messrs. Turnbull are bringing out a stop and junction valve, for which it is claimed that several new and prominent features are introduced, making the valve suitable for all pressures.

THE OBACH DRY BATTERY.—Messrs. Siemens Bros. and Co. are introducing a new dry cell, the invention of Dr. Obach, and it is claimed that this has a higher electrical output than any other dry cell in the market, that it is free from local action and consequently, remains practically unchanged when not in use. The brass terminal is fixed to the carbon electrode in a novel way, whereby corrosion is prevented. The cells are manufactured in four standard sizes, distinguished by the letters A, B, C, and D. Each cell is so designed that a maximum output is obtained with a minimum weight. The large size A is recommended in all cases where a large output or a high rate of discharge is required; for instance, for occasional use with small glow lamps, galvano-cautery, induction coils, &c., as well as for ordinary telegraph work, and specially for cable work. Size B (medium) is for working bells, open-circuit telegraphs, or telephones, portable glow lamps, hotel indicators, railway signalling apparatus, &c.; size C (small) for testing, electro-medical work, &c.; and size D (extra small) for portable testing batteries, and electro-medical purposes. The E.M.F. of the cell is 1·5 volts. Tests given in a pamphlet issued by the makers show that the E.M.F. of some B size cells, stored on open circuit during 10 months, and tested at regular intervals, only amounted to about 4 per cent., thus showing no appreciable local action, and that the cells maintain their initial E.M.F. even during long storage. Even after ten months' storage the internal resistance was found to be only 0·26 ohm, *i.e.*, very slightly higher than at first, and the very small loss principally

Digitized by Google

takes place at the beginning of the storage. Tests are also given of the cells when closed continuously through an external resistance of 10 ohms, until the potential difference had dropped to about half its initial value, and also the subsequent recovery of E.M.F. on open circuit. The figures show that even with such a high rate of discharge the cells last a considerable time. Among other tables given is one showing the results of some practical tests of a battery of 10 cells, size B, connected in series and working a telegraph line with Morse recording instruments, connecting Messrs. Siemens' London office with their works at Woolwich. After 14 months' use, the cells working from 10 to 6 daily, the E.M.F. had decreased but very little, and the internal resistance remained practically the same as at first. The E.M.F. diminished slightly during the first six months, but remained perfectly constant after that time for at least eight months.

Messrs. W. H. Allen and Co.—This firm have completed their new works at Bedford, which are now in working order. The works are built on a site adjoining the main line station, and are therefore very convenient, being only one hour's journey from St. Pancras, London.

Lubricators.—Messrs. W. H. Willcox and Co. have recently brought out a new safety automatic double-feed crank pin lubricator. This is absolutely new, and Messrs. Willcox are the sole makers.

Gas for Domestic Purposes.—Complaint is made by the leading firms of ironmongers of the action of the gas companies in supplying and fixing stoves, chandeliers, and other domestic appliances at a price which practically creates a monopoly for the gas companies in these articles. The result of the action of the gas companies is that many of the leading ironmongery firms find their large stocks thrown on their hands without probable purchasers. It is pointed out that the companies fix and let out on hire a vast number of cooking stoves at considerably less than cost price, making up for any loss incurred by a largely increased consumption of gas at the present heavy price of 3s. 1d. per 1,000ft. It is stated that the number of gas stoves for cooking purposes hired out by the London companies reaches 100,000.

Catalogues.—The Acme and Immisch Electric Works have just issued a new catalogue and price list of Ayrton and Perry's direct-reading ammeters, voltmeters, &c., and of patent cam lock, quick-break lock, and other switches, main and branch distributing switch-boards, the Cockburn reliable fuse, and other apparatus manufactured by the Company. The catalogue is issued in sheet form for handy reference.

Electro-Harmonic Society.—The first smoking concert of the season will be held this (Friday) evening, at the St. James's Hall Restaurant, at 8 o'clock.

Aberdare.—Steps are being taken to form a local company for the purpose of utilising the Provisional Order which has been obtained for the electric lighting of Aberdare, and a deputation has just visited the Pontypool electric lighting station, where the system in use was inspected.

Aberystwyth.—The long-expected testing of the electrical plant took place last week, and everything was found satisfactory. It is understood that the current will shortly be turned on to the lamps on the Esplanade.

Acton.—The Works Committee reported to the last meeting of the Local Board that they had had under consideration two letters from electrical engineering firms with reference to the proposed sale of the Board's Electric Lighting Order, but had not yet come to a decision.

Bacup.—The Bacup Liberal Club is to be lighted and ventilated by electricity at an estimated total cost of £350.

Ballaarat (Victoria).—The Ballaarat Electric Supply Company (Limited), which holds concessions from the City Council, is about to start operations and to erect a plant of the value of £40,000 for the supply of electricity for public and private purposes. The Railway Department has already arranged with them for the supply of current for lighting the Ballaarat station and yards. Prof. Threlfall, of Sydney, and Mr. Ellson, of Adelaide, have been appointed joint consulting engineers for the scheme.

Basingstoke.—The Borough Surveyor has issued a circular to the inhabitants stating that the Town Council have under their consideration the advisability of adopting the electric light, and, as a preliminary, are desirous of ascertaining to what extent private consumers are likely to avail themselves of it.

Battersea.—The Special Committee appointed by the Vestry to consider the question of installing the electric light in the parish have prepared their report. They are strongly of opinion that it would be inadvisable to allow the powers of the Vestry to pass into the hands of a company, and, although they are not at present prepared to recommend the Vestry to take immediate steps to obtain a Provisional Order, they suggest that the matter should stand over with the understanding that the Order be applied for eventually.

Brechin.—Mr. Robert Duke, of D. and R. Duke, Denburn Works, Brechin, has offered to supply current from the firm's works to light St. Ninian's-square, the improvements to which are nearly completed. The Town Authorities are to bear the cost of erecting lamps, &c., for the installation. Mr. Duke's offer has been accepted.

Cambridge.—During the vacation, considerable additions have been made to the supply of current for house, shop and church, but chiefly college, lighting. Ten colleges are connected, and consume large amounts of energy, whilst in Caius and Sidney the light has been installed throughout in place of gas, including courts, staircases, and men's rooms. The New Sidgwick Hall of the ladies' college at Newnham, is wired throughout, and current will be available by the beginning of term. Holy Trinity Church has adopted the light, and the demand for private house lighting is largely on the increase, a mile of main being laid in the growing residential district of Newnham. Messrs. Baily, Grundy and Barrett (Limited), of Cambridge, have been busy with wiring contracts. Owing to the contract with the gas company, which has still some time to run, street lighting beyond a limited amount is in abeyance. To meet the increased demand, a new Parsons steam turbine alternator is being fixed for the winter months.

Cardiff.—At a special meeting of the Corporation on Monday it was stated, in answer to a question, that the electric lighting station would be opened in a week or two.——The Lighting and Electrical Committee of the Corporation have issued a pamphlet containing some particulars for the guidance of intending users of the electric light. The pamphlet gives estimates of probable cost in accordance with the number of lamps required, and briefly describes the advantages of the electric light over other methods of illumination.

Carriage Lighting.—In further reference to the new carriage which has been built for the German Emperor, this is provided with electric lamps, which, it is stated, each contain small accumulators. One is placed on the breast of each horse, another on the point of the pole of the carriage, and others at the sides and rear of the vehicle. By this means the glare is kept from the horses' eyes, and the route of the vehicle is brilliantly illuminated for a distance of about 40 paces.

"Cassell's Popular Educator."—Part I. of the new issue of this well-known publication is just out. Each part is to be copiously illustrated, and the work, when complete, is to contain a number of maps and plates printed in colours.

Castleford (Yorks.).—The Local Board have decided to leave the question of the electric lighting of the town for consideration by the new District Council.

Commission of Sewers (London).—The Commissioners have referred to the Streets Committee the letter from the Post Office authorities, together with the return made by the Postmaster-General to the House of Commons, containing drafts of the proposed new agreements between the Post Office and the National Telephone Company and the "New" Telephone Company.

Country House Lighting.—Messrs. Drake and Gorham have received instructions to instal the electric light in Mr. R. Clifford-Smith's house at Ashford Hall, near Derby. A dynamo of the latest pattern, driven off a water turbine, will charge a battery of 53 D.P. cells. The firm's spring contact main switches will be adopted, as well as a Nevile patent accumulator switch.

Coventry.—The current for the electric lighting of the Technical Institute is, for the present, to be supplied by the Coventry Gas Fittings Company, pending the completion of the Corporation's supply station.

Cowper Street School (London, E.C.).—A series of commercial classes are about to be held in connection with the Old Boys' Club of this school, in which the subject of electricity is to be dealt with by Mr. F. Wyndham Smith. Connected with these classes there is also one for rough sketching for business purposes. Mr. F. R. Taylor, the honorary secretary at the schools, will supply all further information.

Douglas and Laxey Electric Railway.—Mr. R. C. Brebner, contractor for the permanent way of this line, writes to say that, while the trade journals have given credit to the contractors for the engineering portion of the scheme, no reference has been made to those responsible for the permanent way work. The Groudle and Laxey section of five miles, with a masonry viaduct of over 70ft. in height, has been constructed throughout in seven months as a double line, although tenders were originally taken for a single line only. This work has been accomplished by Mr. Brebner's staff and sub-contractors by working double shifts on several sections of the work without any extra charge to the railway company, and for this it is claimed considerable credit is due to those who have done the work.

Dundee.—At a meeting of the Finance Committee of the Dundee Gas Commission on Monday a very satisfactory statement was submitted regarding the income for the past six months for the supply

Digitized by Google

of electric light. It had been estimated that there would be an increased receipt for the whole year of £671; but should the receipts for the second half-year increase at the same rate as in the January-June period that estimate will be considerably exceeded.

ELECTRICAL ENGINEERING IN GERMANY.—It is reported that Messrs. Ludwig Loewe and Co., engineers, Berlin, and the Union Electricitäts-Gesellschaft of the same city, together with a group of bankers, are forming a large new company to carry on an electrical engineering business. The Allgemeine Electricitäts-Gesellschaft of Berlin has, it is stated, acquired land at Wilhelminenhof, on which to establish a large accumulator factory.

THE ELECTRICAL TREATMENT OF MINE TAILINGS.—The South African correspondent of the *Financial News* states that the cost of treating tailings by the new Siemens-Halske electrical process of the Rand Central Ore Reduction Company is stated at 3s. per ton, including 10d. for filling and discharging the vats and 6d. for cyanide consumed. This cost has been tested by actual working for four months, and with a cyanide plant of 6,000 tons to 8,000 tons capacity it is hoped that the treatment can be carried out for 2s. 6d. per ton. The Rand Central Ore Reduction Company, the agents for Messrs. Siemens and Halske, of Berlin, are said to be desirous of a very small royalty—say, 3 per cent.

ELECTRICITY IN MINING.—At the meeting of the Glencairn Gold Mining Company, at Johannesburg last month, the Chairman informed the shareholders that the Directors had increased the electrical plant, and were now pumping from the lower levels to some extent by electric power. This plant, which was now in full working order, was giving every satisfaction.——The General Manager of the Transvaal Gold Exploration and Land Company, for which an electric mining plant has been sent out to South Africa, reports that the foundations for the generator are completed, and that work has been begun on the turbine and generator buildings.

EXPORTS OF TELEGRAPH WIRE AND APPARATUS.—There was a big drop in the exports of telegraphic wire and apparatus from this country during August last, both as compared with the preceding month and the corresponding period of last year. From £303,483 in July the exports last month fell to only £67,550, which is a decrease of no less than £109,309 on the exports of August, 1893. It is a little more satisfactory to turn to the figures, as given below, relating to the exports during the first eight months of the year, as compared with the corresponding periods of the past two years: First eight months of 1894, £1,254,774; 1893, £733,359; 1892, £731,496.

FERMOY.—At the last meeting of the Town Commissioners the clerk read communications received from the Town Clerks of Bray, Carlow, and Kilkenny *re* the cost of electric lighting in those towns, which is supplied by private companies. After some discussion, the clerk was instructed to ask the engineers of the Kilkenny and Bray Electric Light Companies on what terms they would come to Fermoy to confer with the Commissioners, and to prepare an estimate of cost.

FLEETWOOD.—The Fleetwood Commissioners have instructed their clerk to apply to the Board of Trade for an extension of time in which to carry out their Provisional Order. The Commissioners held that this course had been rendered necessary by the neglect of the Board of Trade in not appointing an inspector to hold an inquiry.

FULHAM.—At their last meeting the Vestry decided to adopt the Electric Lighting Acts, and to provide all the necessry plant for street lighting and the supply of current to private persons.

GEELONG (VICTORIA).—The Town Council have appointed Mr. Ellson, of Adelaide, consulting engineer for their light works, which are estimated to cost £16,000.

HOTEL EXPENSES.—Mr. Oswald R. Swete, electrical engineer, was sued at the Worcester County Court by the proprietress of the Feathers Hotel, Ledbury, for the sum of £18. 0s. 5d., the amount of an hotel bill. Defendant admitted the money was owing, but contended that the debt was incurred while he was acting as engineer to the New British Electrical Installation Contractors (Limited), and that that Company were liable for the amount. They were accordingly made a third party to the action. The husband of the plaintiff said that he interested himself in the idea of an electric lighting installation for Ledbury, and called with Mr. Swete upon the principal tradespeople, with a view of forwarding the scheme. Mr. Swete was subsequently engaged in fitting up an installation about a mile from the town. In accordance with his instructions the hotel bill had been sent in to the Company, and the witness stated that although the bill had been several times discussed, on no occasion had the Company repudiated liability; in fact, a portion of the original bill of £21 2s. 5d. had been paid by the Company, this being a charge for posting. Mr. Swete stated that the expenses were incurred in transacting the business of the Company; but whether the Company had benefited by the expenditure he could not tell. He considered the Company had acted very harshly towards him in refusing to pay the bill; but this was repudiated by the Company's counsel, on the ground that Mr. Swete had no authority to incur such charges, or to "do the thing handsomely," as was suggested. In the end the jury found for plaintiff for £17. 18s. 5d., judgment being given against the Company for this amount.

HUDDERSFIELD.—The Town Council have adopted the recommendation of the Rates and Rents Sub-committee that, while no reduction should be made in the charge for the supply of the electric current, discounts, varying from 2½ to 10 per cent., according to the number of units taken, should be allowed. For motive power and domestic purposes other than lighting the current will be supplied at the rate of 4d. per unit.

HULL.—The reduction in the charge for the electric current which has been decided upon by the Corporation will take effect from the beginning of October.——The Hull General Post Office is to be installed for the electric light, the order for the work having been placed in the hands of Mr. G. B. Blanchard.

JOHANNESBURG.—The citizens of Johannesburg are agitating for the Sanitary Board to take over the business of the Johannesburg Lighting Company.

KIDDERMINSTER.—At the last meeting of the Town Council an inquiry was made as to whether the question of electric lighting had been dropped. Between £300 and £400 had been spent on preliminary inquiries, and anxiety was expressed as to whether that was to be wasted. In the absence of the Mayor, who is Chairman of the Law Committee which has the matter in hand, no answer could be given.

KILLARNEY.—At the monthly meeting of the Board of Governors of the Killarney District Lunatic Asylum, on Thursday last week, a report was read from Mr. Walter Leake, who had been instructed by the Board to examine the recent alterations and additions to the Killarney Electric Light Company's station. Mr. Leake reported that a "Giant" turbine of 64 H.P had been added, and arrangements made for the putting down of a second turbine. He was further of opinion that the Electric Light Company were now in a position to supply the asylum with electric current for lighting purposes. He recommends that the contract for lighting the asylum should be for fifteen years, with power to determine in periods of five years, and that the asylum should have the first claim on the output of the Company's station. It was proposed that Mr. Leake's report be printed and circulated, and that its further consideration be deferred until the next Board day; but an amendment that the Killarney Electric Light Company's tender be accepted, that the Board of Control be requested to ratify such acceptance, and that the necessary funds for the electric lighting installation be applied for, was carried by a majority of 1. A protest was handed in by the mover of the original resolution on the ground that no notice had been given of the intention to move an amendment, and notice was given for the next meeting of the Board of a motion to rescind the resolution now carried.

LUTON.—The Town Council last week unanimously resolved to instruct the Highways and Lighting Committee to consider and report upon the advisability of the Corporation applying for a Provisional Order.

LYMINGTON (HANTS.)—At the last meeting of the Town Council Admiral Earle asked if the Public Lighting Committee had ever considered the advisability of having the town lighted by electricity. Many towns smaller than Lymington had the electric light, and it had been found to effect a saving for the ratepayers. The Chairman of the Committee (Dr. Hill) stated that the electric light question had seriously occupied his thoughts, but when the subject was once brought before the Council he understood that it was definitely decided not to substitute electricity for gas.

MAILS TO THE EAST AND FAR EAST.—Mr. T. Carew Martin, of the *Pioneer* of India, writes that an important concession has just been granted by the Post Office in respect to the outgoing Indian mails, which also affects the mails to Egypt, Ceylon, the Straits Settlements, China, Japan, Australia, and New Zealand. At present the latest hour at which a letter for India or the East can be posted on Fridays at Charing-cross Post Office is 7 p.m., at St. Martin's-le-Grand 7:30. From October 5th letters with an extra late mail fee will be received at Charing-cross Station, London, up till 8:10 p.m.

NEWCASTLE.—The *Newcastle Leader* states that the opinions of high legal authorities obtained by the Newcastle and Gateshead Gas Company were submitted at a recent meeting of the City Lighting Committee. Under these opinions it is affirmed that the Company are entitled to charge the town for all the lamps in the streets extinguished by the electric light. The Corporation of to-day are further bound, apparently to the end of time, to pay 1s. a week for each lamp lighted. Councillor Goolden, the present

Digitized by Google

sheriff, took action in this matter some time ago, showing that the city had to pay the same price now, when the net cost of gas to consumers is 1s. 8d. per 1,000 cubic feet, as when the charge was over 4s. But it is in the original bond, and it is probable that the "pound of flesh" will be exacted.

NEWPORT (MON.)—The question of adopting the electric light for the Free Library has been referred by the Corporation General Committee to a sub-committee. It is estimated that the total annual cost will be about £100.

THE "PATENT SOLICITOR."—A summons has been taken out at the City of London Court by the Incorporated Law Society against Mr. Charles S. Hulser for unlawfully acting as a solicitor. The defendant pleaded that he did not know he was doing wrong, as he was only acting as a "patent solicitor." The defendant promised not to use the word again, and agreed to destroy the printed matter bearing the offending word. The case was adjourned for a week to allow this to be done.

POPLAR (LONDON, E.).—The District Board of Works are sending round a circular to the inhabitants, asking if they would take electric current if it were supplied by the Board at 6d. per unit for lighting and 4d. per unit for power purposes.

RAVENSTHORPE (YORKS.).—The electric light has been installed in the stores of the Ravensthorpe Self-Help Co-operative Society. The plant comprises 10 arc lamps of 2,000 c.p. each, and 8 of 1,000 c.p. each, and 7 32-c.p., 90 16-c.p. and 1 8-c.p. incandescents, or a total of 116 lights, representing 29,672 c.p. The current is supplied by a 300-light Kapp dynamo, driven by a 12-H.P. gas engine. The whole of the installation has been put in by Messrs. Ullathorne and Hartley.

RUSSIAN EXHIBITION.—The Russian Government warns merchants and manufacturers that the forthcoming exhibition at Nijni Novgorod is confined solely to Russian products. Persons professing to be agents for space at the exhibition should therefore be distrusted.

SIEMENS-HALSKE PROCESS.—It is stated that the May Consolidated Mining Company has decided to use the Siemens-Halske process in connection with their new cyanide works now constructing.

ST. AUSTELL.—An Indian bazaar is being held at St. Austell in aid of the building fund of the new premises of the local Young Men's Christian Association, and a very attractive adjunct has been provided by Messrs. Veale and Company (Limited), who, in a "Palace of Electra," have an interesting exhibition of electrical apparatus of all kinds.

STIRLING.—A special meeting of the Police Commissioners was held on Monday, when it was decided to apply forthwith for a Provisional Order.

SWANSEA.—The Electric Lighting Committee of the Town Council are engaged in taking preliminary steps towards obtaining a Provisional Order.

THE TELEPHONE AT THE LAW COURTS.—It is stated by the London correspondent of the *Edinburgh Evening News* that the Lord Chief Justice has given permission for an experiment to be tried at the Royal Courts of Justice (London) in the use of the telephone, for the purpose of enabling solicitors and others interested in cases being tried in the courts to listen to what is going on. The experiment is at present being made in the Lord Chief Justice's own court, where, during the recess, a receiver has been placed close to the bench, a second at the desk of the clerk of the court, and a third at the counsels' desk. If the experiment should prove successful, it is stated that the telephone will shortly be introduced into the other courts.

WALTHAMSTOW.—A special meeting of the Local Board has been convened for the purpose of considering the desirability of applying for a Provisional Order.

WANDSWORTH (LONDON, S.W.).—At the meeting of the Wandsworth District Board of Works last week, in reference to notices from the County of London and Brush Provincial Electric Lighting Company (Limited) of their intention to lay mains and construct transformer chambers in roads throughout the district, it was unanimously resolved that the Board disapprove of the proposed works and plans, and that the Company be informed that the Board object to the construction of the transformer chambers in the public way, and to the unnecessary number of crossings proposed.

WELLINGTON (N.Z.)—Considerable dissatisfaction was expressed in the Town Council recently at the unsatisfactory state of the electric lighting arrangements. With the water power and appliances at hand, Wellington, it is said, should be the best lighted city in New Zealand, instead of which it was the worst. A meeting is to be called of the Electric Light Committee, who will go thoroughly into the matter.

WORKS LIGHTING.—Messrs. J. H. Holmes and Co. are putting down a large electric lighting installation at the works of Messrs. George Clarke (Limited), of Sunderland. Forty-five arc lamps, each of 2,000 c.p., will be installed, the current being supplied by two large "Castle" dynamos driven by Crossley gas engines.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by **MR. J. C. CHAPMAN**, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

September 5, 1894.

16,918. A. FOX. London. Improvements in access and junction boxes for electric conductors.

September 6, 1894.

17,000. J. W. ROGERS. London. Improvements in electric arc lamps.

September 7, 1894.

17,047. E. TYER. London. An improvement in electrical lock and block apparatus for railway points and signals.

17,065. S. Z. DE FERRANTI. Liverpool. Improvements in, or relating to, electric cables, wires, or conductors for conveying electricity to vehicles or travelling motors.

17,066. S. Z. DE FERRANTI. Liverpool. Improvements in electric cables.

17,077. W. P. DANDO and J. E. A. GWYNNE. London. Improvements in lenses and electric arc lamps, more especially intended for use for theatrical stage purposes.

17,129. P. STOTZ and F. W. SCHINDLER-JENNY. London. Improvements in electrically-heated soldering irons.

17,130. P. STOTZ and F. W. SCHINDLER-JENNY. An improved apparatus for electrically heating liquids.

September 10, 1894.

17,178. J. P. WEST. London. An improved combined grain cleaner and magnetic separator.

17,180. R. H. JAHR. London. Improvements in electric arc lamps.

September 11, 1894.

17,235. G. L. F. PHILIPS. Holland. Improvements in electrical incandescent lamps.

17,281. W. J. STILL. London. An improved transmitter or transformer for electric currents.*

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1893.

16,307. SWINBURNE. Electric meters.

17,025. SHARP. Electric glow lamps.

17,189. MUNRO and MCFARLANE. Electric switches.

19,688. RICHARDSON. Electrical decomposing apparatus.

19,791. HURTER and OTHERS. Electrolytic cells.

19,934. ABEL (Compagnie anonyme Continentale pour la Fabrication des Compteurs à gaz et autres Appareils). Electricity meter.

20,059. MITCHELL. Medico-electric bands and belts.

23,177. JOLLY (Richmond). Electric time switch, &c.

24,017. STOUTS. Obtaining and depositing metals by electrolysis, &c.

COMPANIES' MEETINGS AND REPORTS.

Direct Spanish Telegraph Company (Limited).

The forty-second ordinary general meeting of the Company was held at the offices, Winchester House, Old Broad-street, on the 21st inst., under the presidency of Mr. Edmund Etlinger.

The MANAGER (Mr. Charles Gerhardi) read the notice calling the meeting and the minutes of the previous meeting, which were approved by the present meeting and signed as correct by the Chairman. The report of the Directors was taken as read.

The CHAIRMAN: Our Chairman, Sir John Pender, is detained abroad, and I have been asked to preside at the meeting to-day. We will go through the report together, and I will make such observations on the different paragraphs as I consider necessary. The first paragraph states that the accounts for the half-year ended June 30th last show, after providing for debenture interest, a balance to the credit of profit and loss of £4,075. 15s. 10d. Last year, at the corresponding period, the balance was £4,645. 13s. 9d. There is, therefore, a decrease in the net receipts of £569. 17s. 11d. As long as trade is depressed—which, unfortunately, we have to hear at every meeting we attend—we cannot expect our traffics to be very high, but we must do the best we can as matters are. The actual decrease in the receipts is £851; but against that we have a saving in debenture interest of £284. 12s. 0d., and a saving in working expenses of £43. 4s. 1d., together £327. 16s. 1d., which leaves a decrease of £523. 3s. 11d. There is, however, a slight addition in extra expenses amounting to £64. 14s., so that our net decrease is, as I have already said, £569. 17s. 11d. The next paragraph deals with the traffic receipts only, and they show a decrease of £868. 12s. 9d. as compared with those of the corresponding period of 1893. There is, however, nothing to be done but to wait patiently until traffic revives; but I may say, with regard to this subject, that quite recently—this month—there has been a marked increase and things look better. Whether that is going to continue or not I do not know, but it looks as if trade has made a fresh start. This may possibly be a great deal owing to the settlement of the new tariff in America, because pending that a great deal of business was not proceeded with at all; but, so far as I am aware—and I have personal experience in the north

Digitized by Google

of England—things are reviving, American trade is improving, and I know that at Bilbao the local traffic in ironstone is beginning to look up. I think, therefore, we may assume that a start has been made in the revival of trade, and if that really is so, we shall be benefited in common with everyone else. The next paragraph refers to the working expenses, which are practically the same as in the corresponding period of last year. They are really £43 less. With reference to this question, I may point out that it is impossible to reduce working expenses simply because your traffic falls off. If you did so you would come to a deadlock the moment traffic revived. The next paragraph refers to our cables, and the land lines connected with them, which have continued in good working order throughout the half-year. That is satisfactory, and requires no comment. Reference is made in the next paragraph to the construction of a new breakwater at Bilbao, which placed the Company under the necessity of moving the shore-end of the Falmouth-Bilbao Cable to a point outside the new breakwater further down the bay. The removal was effected without any appreciable interruption of communication, and the cost is chargeable to the harbour authorities of Bilbao. The harbour authorities found it necessary to construct a new breakwater at the mouth of the river, and that crossed the line of our former cable. We therefore had to take the cable up, and move it outside the new breakwater. The work necessitated the sending out of a ship, and also the construction of a mile and a-half of additional land lines. The cable work was done, with their usual skill and rapidity, by one of the steamers of the Eastern Telegraph Company, and the land lines were constructed by our superintendent, who is a very capable man. With respect to the outlay on this work, very little cost was incurred during the half-year to June 30th. The accounts had not been settled and they are not settled now, but the small amount we had paid up to that date is included in the balance-sheet under the heading of "Amounts due outstanding," because the authorities of Bilbao are chargeable with the whole of this outlay. The actual amount involved in the work we cannot tell yet, as the accounts are not prepared. The next paragraph deals with the debenture question, and we say: "The £62,000 Six per Cent. Debentures, which matured on May 1, 1894, have been paid off, and £30,000 new debentures have been issued, bearing interest at the rate of 4½ per cent. The difference of £32,000 was provided for by making the final call of £1 per share on the 12,931 Ordinary shares, and by taking £19,069 from the reserve fund."

When the time came for paying off the £62,000 of our old Six per Cent. Debentures there were various ways of carrying out this measure with our resources, and after a great deal of deliberation we came to the conclusion that the way mentioned in the report was the best all round. The effect on the Company by the change is as follows: The £62,000 of Six per Cent. Debentures absorbed annually £3,720 in interest. The £30,000 of new debentures, at 4½ per cent., will require only £1,350 per annum. Therefore there is an apparent saving of £2,370 annually. I say "an apparent saving," because, as we have taken from the reserve fund £19,069, we must allow the loss of interest on this sum, which, as it yielded 3⅓ per cent., amounted to £630. The net annual saving, however, is £1,740. Our idea is to create a fund to redeem the £30,000 of new debentures within twenty years, and for this purpose we ought to set aside £1,120 every year. Taking that from the £1,740 there would remain a net balance of £620, which is as nearly as possible equal to 1 per cent. on the whole of the Ordinary share capital of the Company paid up. On the whole, therefore, this operation is a profitable one for the Company. The position will be that if we have a normal traffic we shall be able to provide for the debenture interest, the debenture redemption, the interest on the Preference shares, and £5,000 a year for the reserve fund, and we shall then have 1 per cent. to add to whatever dividend we earn from the traffic only. I think you will consider that that is not a bad arrangement. The next paragraph deals with the appropriation of profit. After adding the usual sum of £2,500 to the Reserve Fund, the Balance of Profit and Loss amounts to £1,575. 15s. 10d. To this the Directors propose to add £951. 15s. 10d. from Interest and Profit on Investments, and recommend the payment of the dividend at the rate of 10 per cent. per annum on the Preference shares, and a dividend, free of Income Tax, of 1s. 8d. per share, being at the rate of 4 per cent. per annum on the capital paid up from the due date of payment, on the Ordinary shares of £5 each. We have never before paid a dividend of so much per share; it has always been so much per cent., but this year we had to act differently, as we had to pay a dividend on £4 per share for six months, and on £1 per share from the date the call was made to the end of June. That made it a complicated affair, and it could not be worked out at per cent. We therefore say so much per share, but it is the same as before, practically 4 per cent. I hope, however, that we shall go back again to the system of per cent., as it requires a little mental effort and possibly the use of a pencil and paper to work it out when a dividend is declared of shillings and pence per share. The reserve fund will now amount to £21,270. 19s. 11d. The last paragraph of the report is as follows:—

"As the attendence of Shareholders at the Autumn General Meetings is very small, and as the Articles of Association require only an Annual Meeting to be held, the Directors propose that in future only one General Meeting shall be held, viz.:—in the month of March, but intend to pay an Interim Dividend in October, if earned." You are all aware that the attendance at the autumn meeting is very small, and, as you know, the preparation of the accounts in your hands occupies a good deal of the time of the staff, besides which these meetings cost money—not any large amount, but still a sum which is worth saving. The Directors think it will be satisfactory to the shareholders if the meetings are held once a year, as contemplated by the Articles of Association. If anything extraordinary happened, we should, of course, have to call you together, but practically I should think that one general meeting a year will answer our purpose. I now propose—

"*That the report and accounts now presented be and are hereby received and adopted.*"

Mr. JOHN DENISON PENDER seconded the motion.

Mr. COCHRAN said he did not know whether he quite understood what was proposed by the Directors; but he gathered, from what the Chairman had stated, that they proposed to set aside, out of the profits, a sum of about £6,150 a year. It seemed to him that this was laying a rather heavy burden upon so small a Company, for what was proposed would take a large slice of the profits. Some of them had been shareholders for a long time in the Company, and had had experience of its bad and its better times. He had always been a hearty supporter of the Directors in making the Company a sound one, but he thought that the Board were now disposed to put rather a stiff screw on the shareholders. He congratulated the Directors on the result of the operation which had got rid of their Six per Cent. Debentures, replacing them by others bearing only four and a-half per cent., and wiping off nearly half of the debenture liability. Having done so much, however, and having now acquired the basis of a fairly respectable reserve fund, he thought that the Directors should deal with a somewhat lighter hand with the revenue of the Company. Unless under exceptional circumstances, he thought that they ought to be contented with the setting aside of £5,000 a year out of the revenue. The shareholders had received only a very moderate dividend for a commercial venture, and only on one-half of their capital. He thought the Directors ought to reconsider the matter before imposing the proposed additional burden on the net revenue of the Company.

The CHAIRMAN, in reply, said that the Directors fully sympathised with what Mr. Cochran had said. No one was more anxious to get an increased dividend than the Board, but they had to consider not only the question of what was advantageous to each individual shareholder, but what was best for the Company as a whole. The £5,000 a year which they placed to the reserve fund had always been regarded as a right and proper proceeding, and, in fact, if they had not made this provision, the shares would have been at a large discount instead of at par. A cable company without a large reserve fund was a thing without a foundation. As regarded the amount which they proposed to set aside for the redemption of the present debentures, what they were aiming at was to free the Company from all debt. If they could set aside a sum which would extinguish the whole of the indebtedness of the Company in 20 years, its position would be vastly strengthened, and although they might for some years, assuming that the traffic did not increase, receive only a reasonable dividend, still they would have in prospect a position of considerable prosperity. The great thing in a concern such as theirs was to have a backbone in the shape of a reserve fund, to do away with indebtedness and then to "pocket" the difference. They had well considered the matter, and he really did not think it would be wise to raise their dividend by not making provision for the redemption of the debentures. They had placed the amount of the debentures at a moderate sum, and they ought to make provision for redeeming them. When they had Six per Cent. Debentures out they made no provision, but they knew that when the time came they would be able to issue new debentures at a low rate, which 4½ per cent. was if the Bank rate went up to the same rate. The shareholders, who had for the most part taken the debentures, must regard the provision of a redemption fund as a protection of their interest. If the Bank rate went up to 5 per cent. they would not be able to replace the present debentures, and they would have to go back to Six per Cent. Debentures again. He thought that the Directors were acting only wisely in what they proposed to do in this matter. As an individual shareholder he would certainly like a larger dividend; but, as he had said, they had to look at what was best for the Company as a whole.

Mr. DYETT inquired at what rate the new debentures were issued, and if any were left.

The CHAIRMAN replied that they were issued at par, and they had all been taken up. The amount applied for was in excess of what they had to place. With the present Bank rate the interest of 4½ per cent. seemed large, but it would not appear so if the Bank rate went higher. It was a reasonable rate of interest, and anyone who held the debentures was justified in expecting that the Company would make provision for their redemption. He then put the resolution, which was carried unanimously. He afterwards proposed the payment of the dividend at the rate of 10 per cent. per annum, less income-tax, on the Preference shares, and of a dividend, free of income-tax, of 1s. 8d. per share, being at the rate of 4 per cent. per annum on the Capital paid up from the due date of payment, on the Ordinary shares of £5 each.

Mr. J. D. PENDER seconded the motion, which was carried unanimously.

Mr. COCHRAN then proposed a vote of thanks to the Chairman and Directors. He said he still thought that the Directors were laying rather a heavy burden on so small a Company, although if prosperity should set in and larger profits be made, the shareholders would not feel it so much as they otherwise would do. As to the prospect of any great increase in the Bank rate, he shared the view which was entertained generally by financial people, that the present position was likely to be very largely permanent. He thought that the security for the Company's Four and a-Half per Cent. Debentures was not a bad one, considering the rapid way in which the reserve fund was being built up. However, the Directors were entitled to their own view, and, after all, if there was any fault it was on the side of safety.

Mr. DYETT seconded the motion, which was carried unanimously.

The CHAIRMAN briefly acknowledged the vote, and the proceedings then terminated.

Edmundsons (Limited).

We have been favoured with the following report of the proceedings at the sixth annual meeting of the above Company, held at the offices, Great George-street, Westminster, S.W., on the 13th inst., Mr. J. W. Edmundson presiding:—

Digitized by Google

"The report and statement of accounts were taken as read. In moving the adoption of the report, the CHAIRMAN congratulated the shareholders upon a satisfactory year's working. Although the profits for the past year were not so large as in several previous years, they were satisfactory when the great depression in trade and the large amount of competition were taken into account. The outlook for the present year was satisfactory, as they had a larger amount of work in progress than was the case at the same time last year, including, among other installations, the lighting of Warwick Castle, Duncombe Park, Elveden Hall, Copped Hall, Nidd Hall, Wood Hall, and the New Asylum for Sunderland. An important contract had also just been signed for lighting a portion of the town of Shrewsbury, provision being made in the first instance for 5,000 lights, and the Directors hoped that they might be able to extend the Company's operations in this class of work. The report and accounts were unanimously adopted, and a resolution passed directing the payment of a dividend at the rate of 6 per cent. per annum, on both Preference and Ordinary shares. Mr. Henry Wigham, the retiring Director, was re-elected, as were also the auditors, Messrs. May and Street."

Brush Electrical Engineering Company (Limited).

The following is the fifth annual report of the Directors of this Company, for the year ended June 30th last, to be presented to the shareholders at the general meeting to be held at Cannon-street Hotel, London, E.C., on Monday next, October 1st, at 3 o'clock :—

The profit and loss account shows a gross profit of £57,157. 19s. 4d. After deducting general charges, maintenance of buildings, plant and patents, interest on debenture stock, and sundry costs of removal, which the Directors consider should be written off the year's profit, there remains a net balance of profit amounting to £27,280. 12s. 1d., to which must be added the sum of £815. 5s. 3d., the balance brought forward from last account. After providing the full dividend on the Six per Cent. Preference shares for the year, and an interim dividend at the rate of 5 per cent. per annum, which has already been paid, on the Ordinary shares for the half-year ended December 31st, the Directors recommend that a further dividend, at the rate of 5 per cent. per annum, be paid on the Ordinary shares for the six months ended June 30th, leaving £3,788. 9s. to be carried forward.

During the year the sum of £3,710. 13s. 7d. has been expended on the purchase of additional plant and extensions at the Loughborough Works, where the whole of the regular home manufacturing work of the Company is now concentrated and carried on. The volume of business which the Company has been called on to undertake during the year, is again in excess of that in any previous period of its existence. The prevalent industrial depression has, however, brought with it increased competition and a general fall in prices, with consequent diminution in the rate of profits obtainable.

The Company's Vienna factory has yielded improved results during the past year, and shows a fair return upon the capital employed. Important central station contracts have been successfully carried out, and others are in course of execution. The glow lamp department has during the year largely increased its output, and is now manufacturing at the rate of half a million lamps per annum. The Australian branch of the business has laboured under great disadvantages, arising out of the financial crisis through which the Colonies have recently been passing ; under these circumstances the Directors are glad to be able to state that the bad debts incurred during the year amount to less than £50, and consider that great credit is due to the careful management with which the business has been conducted.

The works of the Company are at present fully employed, and the prospects for the coming year are satisfactory. The progressive change in the character of the industry from the lighter class of electrical engineering involved in numerous and isolated installations, to the heavier and more considerable works following upon the extension of electricity supply from central stations, is undoubtedly favourable to this Company. The contract with the City of London Electric Lighting Company for the supply and erection of generating plant and accessories for public and private lighting in the City of London has made satisfactory advance during the year. Contracts have also been entered into with the County of London and Brush Provincial Electric Lighting Company for the supply of plant and equipment of central station undertakings for the districts of St. Luke's, Wandsworth, and elsewhere.

Mr. Arthur Ayres, M.Inst. C.E., has accepted a position upon the Board, to fill the vacancy created by the death of the late Duke of Marlborough. Mr. A. H. Sanderson and Col. F. G Steuart retire by rotation, and, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Brothers and Co., also retire and offer themselves for re-election.

WESTINGHOUSE ELECTRIC COMPANY (LIMITED).—A meeting of the shareholders of this Company was recently held, at which the report of the Directors for the year ended September 30th last was presented. The Directors point out that the issue of the report and balance-sheet and the announcement of the annual meeting was delayed in consequence of pending negotiations between the English and American companies. There is a net profit for the period under review of £6,782, which, to the sum of £6,015 brought forward, leaves an amount of £13,015 to be dealt with. During the year 4,700 Shallenberger meters have been disposed of, as compared with 3,100 of the previous year, and the first eight months of the current year show a continued increase. Mr. Albert Kapetyn has been elected to a seat on the Board of Directors, vice Mr. J. D. Gibbs, who retires.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.*]

CAPSULE BATTERY COMPANY (LIMITED).—This Company was registered on September 25th, with a capital of £30,000 in £1 shares, to acquire patents and patent rights for galvanic batteries, electric call bells, and for or connected with brushes or other appliances for the curative application of electricity, to use electricity and every description of electric or electromagnetic appliance for purposes to which the same is applicable, and to carry on the business of electric, galvanic, and mechanical engineers, suppliers of electricity and galvanism, and manufacturers of and dealers in apparatus required for or capable of being used in connection with the generation, accumulation, supply, distribution, or employment of electricity or galvanism.

CARBON SYNDICATE (LIMITED).—This Company was registered on September 19th, with a capital of £100,000 in £1 shares, to carry on the business of manufacturers of and dealers in carbon plates, slabs, rings, crucibles, rollers, bars, rods, pipes, and other articles for electrical, electrolytical, or other purposes ; electricians, electrical and mechanical engineers, suppliers of electricity, manufacturers of and dealers in and agents for the sale of all apparatus used in connection with the generation, distribution, supply, accumulation, or employment of electricity, &c. The first Directors are Sir Coutts Lindsay, Bart., Charles P. Shrewsbury, John Cooper, and Frank L. Marshall.

TAYLOR, RIDER AND CO. (LIMITED).—This Company was registered on September 25th, with a capital of £2,500, in £1 shares, to acquire the businesses carried on by "Taylor and Rider," at 12, Albert-street, Deansgate, Manchester, and by James Grime, at Reynold-street, Hyde, Cheshire, and to carry on the business of sanitary, ventilating, lighting, heating, and electrical engineers, boiler makers, &c., heating apparatus manufacturers, &c.

CITY NOTES.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have resolved, after placing £6,000 to the credit of the renewal fund, to declare an interim dividend for the quarter ending September 30th of 9s. per cent. on the Ordinary Stock and 18s. per cent., on the Preferred Stock, less income tax, payable on November 1st.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended September 23rd were £835, as against £775 in the corresponding period of 1893, being an increase of £60. The total receipts for the half-year amount to £10,237, as against £9,681 for the corresponding period of 1893, an increase of £556.

EVERED AND COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend at the rate of 7½ per cent. per annum for the half-year ended June 30th last.

THE HOPCRAFT FURNACE.—The Engineering and General Contract Corporation is intimately associated with this furnace, from which high results were promised. These results have not been forthcoming, and the Hopcraft Furnace Company has proved a failure. This led to the appointment some time back of a committee of investigation to inquire into the methods adopted in floating the Furnace Company, and into the future prospects of that concern. The committee have just presented their report, in which the policy of the Directors is condemned in strong language. The report states that no attempt has been made to manufacture the Hopcraft furnace nor to remedy any of its notorious defects, that all engineering work has practically been abandoned, and that the condition of the Company's works and the costly machinery reflects discredit upon all concerned. Gross irregularities have also been allowed : no imputations on the honour or the integrity of the present Directors is alleged, but the irregularities referred to are ascribed to lack of knowledge or business experience. A separate report states that with regard to the Unity Engineering Works, East Greenwich, these are situated on the most remote and inaccessible part of the marshes, and the Company have them on their hands for an unexpired term of 18 years at a nominal rent. This report concludes :— "The valuable shafting is now mainly used as hen roosts or perches, the pattern-making shed as a carriage painting shop, the open shed as a stabling for some rough horses, all the property of the so-called caretaker, the whole presenting a most incongruous and dilapidated appearance. There are some few small upright engines which have apparently never been used, but which are now, through utter neglect, quite useless. Any evidences of the Hopcraft furnace beyond a few patterns and some gilded signboards are conspicuous by their absence, and there is nothing further to betoken the once alleged famous invention."

PRETORIA LIGHTING COMPANY (LIMITED).—The offices of this Company have been removed to 120, Bishopsgate-street Within, E.C.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended September 21st (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £3,598.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 855.—Vol. XXXIII. FRIDAY, OCTOBER 5, 1894. PRICE FOURPENCE *Annual Subscription (U.K.), 19/6*

NOTES.

In an article dealing with electrically-driven coal-cutters, which will be found elsewhere in the present issue, the author adverts to what may be termed the extraneous difficulties to be overcome before the community will be allowed to reap the full benefit derivable from the application of electric energy to the winning of coal. The mechanical engineer, it would appear, has brought the electric coal-cutter to such a point that as regards first cost, durability, reliability, and coal-getting capacity it would, if properly made use of, materially reduce the cost of winning a ton of coal.

To have done this is, however, only half the battle. The human mind obeys the first law of motion with irritating obstinacy. Everyone would, if he could, continue in a state of rest or of uniform, and usually uncommonly slow, motion in a groove, except in so far as he is compelled by force to hurry along or altogether come out of that groove. So long as miners were amenable to stock arguments and the public would pay the piper, the colliery manager, good easy man! not being acted upon by any external force, continued to do as he had always done, and if he did introduce coal-cutting machines, did so tentatively, half-heartedly, and without making adequate arrangements, mechanical or manual, for quickly clearing away the coal which was cut, so that the cutting plant was forcedly idle half the twenty-four hours. Then when one comes to the men themselves, it is too much to expect *them* to assist, by making their extinguisher as great a success as possible, in what they consider must lead to their own extinction. So that the community will have to await the advent of an external force before it can hope to reap any appreciable advantage from the ingenuity of the engineer.

The increasing disposition of the miner to capture all he can of the profits of capital, and the increasing indisposition of the public to bear the burden of high wages, are indeed potentially such a force. But, given a new colliery, started from the very beginning on the new lines, it ought, if there be any virtue in mechanical appliances, to be able to undersell. Once this possibility is made plain, as we anticipate it shortly will be at Eckington, the uniform motion of managers and men in a narrow groove will be effectually disturbed by the never-failing force of competition

Were it not for commercial considerations a most interesting Paper might be written for the Institution of Electrical Engineers on the use of steel for dynamo construction. But fear of mentioning makers' names, either in praise or disparagement, makes such a Paper impossible. The tracings of tests of steel which were handed round in the course of a recent Paper on magnetic testing were of little or no interest, since the names of the makers had been cut out. From a purely scientific point of view, nobody cares about the makers' names, and Prof. Ewing's book on "Magnetic Induction in Iron and Other Metals" loses nothing in scientific interest or usefulness by any such omissions. The employment of cast steel for dynamo magnets is not a mere matter of high permeability and few ampere turns, it is a complicated commercial question. Copper and total weight may be saved, but the cost of the material and of the tooling is greater, sometimes much greater than with cast or wrought iron. This question cannot be settled once and for all, each dynamo builder must find out for himself which material is best suited for his make of machine, for his tools, for his men, and for his market; and this is no easy task. In the works of one of the largest and most scientific dynamo makers we saw recently a great variety of steel magnet bars and castings, and there seemed to be scarcely two of the same kind. There was Gruyère steel, worm-eaten steel, wasp's-nest steel, and steel which looked like a longitudinal section of cane seen through a microscope. Drilling and tapping such stuff is no child's play.

It is quite the exception to find apparatus for testing magnet steel in a dynamo factory, not, we are inclined to think, because dynamo makers are not alive to the importance of high permeability and low hysteresis, but because they know that a scientific test of the material, even accompanied by a report from a high authority, saying "Decidedly superior to wrought-iron forgings," or "I have not hitherto met with any material so well suited for use in the field-magnets of dynamos," cannot settle the question whether it will pay them to use it. Nothing but the building of a dynamo and a careful noting of its cost of building, and of its output, will suffice; and they are well aware that, even having done this, they may never get a piece of the same quality again. But dynamo builders need not be utterly in the dark about the magnetic qualities of steel, even if they have no testing apparatus, for more than one maker is issuing particulars of tests. We have before us a pamphlet from Messrs. Edgar Allen and Co., in which a large number of

Digitized by Google

B H curves are given, to large scales, together with reports by Prof. EWING and others, giving also permeability, coercive force, and remanence. Makers of sheet iron for armatures and transformers are also beginning to give such information, which ought also to be valuable. A matter of equal importance is the ability of a maker to supply more material of exactly the same quality. This Messrs. ALLEN and Co. profess to be able to do.

AN exhibition of various systems of photography by artificial light is being held at the office of *The Photogram*, in Farringdon-avenue. The Pilsen arc lamp, which has been described in these columns, and the Adamson system of glow-lamp lighting, are the two representatives of electric light methods, and they seem to hold their own against magnesium and Welsbach gas burners. The Adamson system consists of a ring of 40 25-c.p. lamps and a compound switch. The lamps are placed round the inside of a white dome reflector about 3ft. 6in. diameter, hung on a long counterpoised lever, allowing adjustment. Lamps of nominal 65 volts are used, but are run up during exposure to 100 volts. It is claimed that an exposure of one second will suffice for a portrait. For focussing and posing, 8 lamps at 65 volts are employed, and by means of a twenty-point switch, any number of pairs of lamps can be switched on. A second switch handle regulates the resistance. The over-run lamps, of course, give a fairly good actinic light, and the apparatus seems easy to control.

"DEADLINESS," like most things on this sublunary sphere, is relative, and the American trolley car, regarded purely as a man-slaying instrument, is doubtless quite innocuous when compared with the American level crossing; and, taking the latter as a standard, our transatlantic electrical contemporaries are probably quite justified in refusing to allow the epithet "deadly" to be applied to the trolley car. It is, however, only a very high standard that could prevent the record of the Brooklyn City Railroad from fully entitling its trolley cars to the adjectival prefix "deadly." During the year ending June 30th twenty-three persons were killed and thirty-nine were injured on the various Brooklyn City Railroad trolley lines. Of those killed two were passengers and three employés.

Cable Interruption:

	Date of Interruption.
Zanzibar-Mombasa	September 4th.
Macao-Hong Kong	September 25th.

"L'Energie Electrique."—Under this title there has just appeared in Paris the first number of a semi-monthly publication, which proposes to become the organ of "factory-owners, consumers and municipalities."

How Gas Proposes to Fight Electric Light.—The Launceston (Tasmania) Gas Company, finding that "they would in the future have to compete against the electric light," have decided to reduce the salaries of their staff by 10 per cent.

Provincial Municipal Electric Lighting.—The Mayor and Corporation of Aberystwyth have inaugurated the electric lighting of the marine front and main portion of the town. The lighting was carried out by Messrs. Bourne and Grant.

Electric Traction in Spain.—A concession has recently been granted for the construction and operation of an electric tramway giving communication between Barcelona and the suburbs of Sarria, Gracia, San Gervasio, San Martino and San Andres.

Interurban Telephonic Communication.—Telephonic communication was made available between Hamburg and Cologne on the 1st inst. The charge is 1s. for three minutes' conversation.——On the 1st inst., the telephone line between Ipswich, Colchester, Chelmsford, London, and Brighton, was opened for the public use.

Institution of Civil Engineers.—A recently-issued list of members, corrected to September 6, 1894, shows that there are now on the roll of the Society 19 honorary members, 1,837 members, 3,597 associate members, and 358 associates, together 5,811. The students attached to, but not forming part of the Corporation, now number 782.

International Telephony.—In the Danish Rigsdag recently, the Minister of Finance, in bringing forward the budget for 1895-96, demanded credits for the establishment of a telephonic service between Fyen, viâ Jütland, to the German frontier. This line is intended to form a link in eventual telephonic communications between Copenhagen, Hamburg, and Kiel.

French Telegraphic Rules and Regulations.—M. de Selves, the Director of Telegraphs, has, says *The Times* correspondent at Paris, given way, as was expected, to the outcry against his regulation ordering telegrams to be fully addressed. He has given instructions "that all telegrams, the address of which is sufficient to indicate the recipient without search or application for information, shall be delivered without delay."

The Proposed Pacific Cable.—The officers of the British cruiser "Champion," which vessel has recently surveyed Neckar Island, one of the suggested landing points for the Pacific cable, reports that under no circumstances would the island prove suitable for the landing of a cable, as the shores rise precipitously from deep water. This may, however, be said of most of the possible Pacific landing points, and the difficulty has been overcome in the cases of Madeira and St. Vincent by the use of a special type of cable.

Military Telegraphy.—In his account of the recent cavalry manœuvres *The Times* correspondent says:—"This was the first day on which the R. E. Field Telegraph was employed; it advanced *pari passu* with the eastern force, and constantly wired to Churn Camp, some twelve miles distant, reports of progress. On this and subsequent occasions, it accompanied cavalry at a trot, the wire being laid as fast as the cavalry advanced, and also being reeled up equally rapidly, even when the cavalry retired at the same pace. This is a most creditable performance, the more so because the R. E Telegraph Battalion has not professed to be able at present to accompany cavalry in the field. The possibility of the wire being utilised with cavalry having been thus demonstrated, the necessary organisation will, no doubt, be supplied."

Meter Testing.—It is a common experience with suspicious gas consumers that their meters, when tested, are certified as registering too low, with the irritating result that they not only have to pay the cost of the test, but receive the added insult of having their gas more accurately metered by a new meter. Electric meters, if we may judge by a paragraph in the annual report of the Surveyor to the Chelsea Vestry, propose to follow in the same path. Only one application was made to the Vestry during the year to have a meter tested, which was from 59, Cadogan-square. Mr. Morgan Williams tested it on behalf of the Vestry, and found that at the average load it registered 8·27 per cent. too low. It is needless to state that the Supply Company, on receiving this intimation, immediately fixed a new meter.

Local Authorities and Telephone Poles.—The Fife County Road Board says the Telephone Company must pay 2s. each for their poles or lift them. On the north side of the Tay some months ago the question of way-leave and rent, says the *Dundee Advertiser*, was fully debated; but the local authorities who entered into the discussion were scarcely so well prepared as the Fife folks. The latter have ascertained not only the capital and working expenses of the Company in Fife, but the amount of their income, and thus they are able to dictate their terms in no uncertain fashion. The increase in the rent

Digitized by Google

is a heavy one; but the total sum demanded by the Board, when considered in relation to the amount earned by the Company in the county, is not unreasonable. Whether they think so or not, it is quite evident that the Company will be made to pay or lift.

Peculiar Effect of the Aurora.—A correspondent of the *Electrical World* of New York, relates that he had to use very frequently the telephone line from Digby to Westport in Nova Scotia, a distance of about 50 miles. The line is a single iron wire with earth return. The instruments used were ordinary Bell short distance telephones. There were no other wires within fifty miles. Whenever there was an aurora, or an electrical storm, he noticed the following phenomena: A person talking at the west end of line could be heard quite distinctly at the east end. But the person at the east end could not be heard at the west end at all, and the conversation would have to be repeated in the centre of line. During normal weather conditions conversations could be carried on distinctly in both directions, but always with an advantage from west to east. There is no question, he states, about the instruments, as they were exchanged without any change in the working being noticed.

A Constant and Reliable Battery.—A consulting engineer was being "pumped" in a friendly and unprofessional manner by an acquaintance, the other day. "You engineers," said the inquirer, "are prejudiced in favour of dynamos and steam engines for electric lighting, just because they are better for trade than batteries. More electricity is turned out from batteries all the world over and all the year round than from dynamos, but you combine together to prevent men like me from lighting their houses in a modest way with a simple battery. Now, tell me, are there not really constant and reliable batteries that you yourself use, perhaps not for electric lighting, but for other purposes? You say they are not suitable? Leave that to me, I'll see about that. What are they called, and how many go to the hundred, for you see I *do* know something about it?" "The Clark cell," replied the patient consulting engineer, "is recognised as the most constant and reliable battery. You must use 70 to get 100 volts."

Three-Wire System of Electric Traction.—Mr. A. G. Seaman writes us as follows:—

I have only just seen in your number of September 14th the account of the trolley line at Bangor, Me., by Mr. J. G. Carrol. I never had had any doubt as to the practicability of applying the three-wire system to small lines, but I had doubted whether it were worth the while. The line at Bangor is to a certain extent exceptional at present, owing to the comparatively long distance from the power house, and ought to be of considerable interest to similar places possessing water power. The difficulties do not lie on the line; but as I hinted in my letter of August 28th, and as Mr. Carrol points out himself, in the power house. The necessity of having to start two dynamos (one on each side of the system) as soon as the load becomes too much for those already running, and the loss of economy, due to the small load factor of the plant, occasioned thereby, most particularly in the power stations of trolley systems, where the load factor is never too good, the increased necessity for further spare plant, and the additional complication in the switchboard arrangements, have probably prevented the three-wire system from making way in traction work. These difficulties are being met in many lighting stations in London and elsewhere by winding the dynamos for the full pressure of the system, *i.e.*, in a case where there are 500 volts between each trolley wire and earth, the earth being the neutral or third wire, by winding the dynamos for 1,000 volts, and equalising any difference of demand in the two halves of the system by means of accumulators or motor transformers; these latter should be placed at the most central points in the distribution system. By this means the advantages of the three-wire system may be combined with the simplicity of the parallel system, with the gain of considerable economy.

An Interesting Isolated Electric Lighting Plant.—Mostyn House School, a preparatory school for boys, at Parkgate, Cheshire, has recently been fitted up with an independent electric light plant. The plant consist of a 12½-H.P. Hornsby-Akroyd paraffin engine, driving a Paterson and Cooper dynamo, and a double set of March's accumulators, running in parallel with the dynamo during the hours of maximum output. Current is thus supplied to 153 incandescents and one arc lamp. A novel feature of this plant is a set of electrically driven clocks, distributed all over the building. They are synchronised from one central self-winding clock, and all keep exact time with one another. The power is derived from a small battery of accumulators kept constantly charged by the lighting circuit. At fixed hours bells are automatically rung in all the various class-rooms and living-rooms. These hours are determined by a plug-board in the headmaster's room, and can be varied at pleasure to any given multiple of five minutes. It is satisfactory to notice that the cost of running compares very favourably, in actual cash expenditure, with the previous annual outlay for gas and oil lamps.

The Accident at Bankside.—Last Sunday afternoon two employés of the Brush Company were repairing one of the switch pillars which stand about 20ft. apart along the switch gallery of the station at Bankside. One of the men—a fitter—was at work behind the pillar about 5ft. from the gallery floor, having used a ladder for getting up. His labourer, a man named Hearne, took the ladder away unnoticed, placed it against an adjacent pillar which was "alive" at the time, and went up to the top where the only exposed contacts are. The first intimation that anything was wrong was conveyed by a scream from the injured man, and on the fitter coming round to the front he saw his mate lying on the gallery. He jumped down, and with the assistance of the station hands, who were soon on the spot, tried to resuscitate the man, but their efforts were unavailing. A doctor arrived shortly after the accident, but he immediately pronounced life extinct. The deceased had been employed on work of the same kind for about two months and knew thoroughly the danger of touching anything. Only 15ft. from where the accident occurred a notice was displayed absolutely forbidding anyone to do the very thing which led to the man's death. The pressure was 2,000 volts alternating.

Subjects for Papers.—The Council of the Institution of Civil Engineers invites original communications on the following, amongst other subjects:—"The Different Methods of Governing Steam Engines, so as to give Uniform Speed with Greatly Varying Loads"; "The Arrangements of Boilers and Engines best Adapted for Electric Light Stations under Different Conditions"; "The Purification of Sewage by Filtration, Precipitation, Electrolysis and otherwise"; "Alternate *versus* Continuous Electric Currents for (*a*) Electric Lighting, and (*b*) Transmission of Power"; "The Forms of Electrical Conductors for Lighting, Stationary Power, Heating, and Tractive Purposes"; "The Utilisation of Electric Lighting Plant during Hours of Small Demand"; "Electric Lighting and Haulage Plant in Mines and Collieries"; "The Application of Water Power, and its Transmission to a Distance by Electricity"; "Electrical Motors for (*a*) Inland Navigation, and (*b*) Ocean Vessels"; "The Use of Electrical Motors for Driving Machine-tools in Engineering Workshops"; "Coal-winning in Seams Situated at Great Depths below the Surface"; "The Effect of Small Quantities of Impurities in Commercial Copper as Regards its Use in Electrical Work"; "The Electrolytic Deposition of Copper"; "The Uses of the Rarer Metals, and the Modes of Extracting them from their Combinations"; "Aluminium, its Manufacture, Properties, Uses and Alloys"; "The Arrangement of Engineering Workshops, with Descriptions of Modern Machine Tools and Appliances."

Electrical Communication with Lightships.—The following letter from the Rev. T. Hancocks, which recently appeared in the *Daily Chronicle*, is of interest:—

SIR: My attention has been called to a statement in your paper, in which Mr. Julius M. Price declares that electrical communication with lightships is a failure. Kindly insert this correction, as one fact is worth many theories. The Goodwin lightship, situated at the north end of the Goodwin Sands, is connected with the shore by telephone. No part of the planet is more perilous than this spot, and the vessel is fully exposed to what sailors call "a breeze." Yet for seven months the telephone has worked admirably, as my experience tends to prove. One of her crew, a member of my church, had a son critically ill ashore, while his father was doing his two months on board. To relieve his anxiety I obtained permission at the coastguard station to speak the lightship. I told him the home news, had with him a general chat, and bade him good night. I easily recognised his voice, quite as well as I ever heard one through a land telephone, and the Goodwin is over six miles from shore; also, the officials assure me that the telephone is a complete success. There are only two drawbacks:—(1) The chafe of cable near the ship necessitates frequent repairs. Experience will soon suggest some safeguard. (2) The ship does not ride rough seas so lightly as before, owing to her being anchored by four heavy chain cables instead of one. This, while no danger, is less comfortable for the crew, as she ships more seas aboard. It has been suggested that each cable should be supported by a buoy, which would probably remove this defect. But already this telephone has proved its immense value in saving precious life and valuable property. At a wreck,

Digitized by Google

as at a fire, the first five minutes are worth the next five hours, and since the cable, news of a ship on the Goodwins has reached land, the lifeboat has been dispatched, and all hands saved, with a speed incredible to former times. The cable is no failure, but a thorough success.

Aluminium.—It must be confessed that up to the present the uses which aluminium has been put to in the arts has scarcely come up to the high expectations of those who prophesied a metallurgical revolution as soon as aluminium could be obtained comparatively cheaply and abundantly by means of the electric furnace. Practically all that had been done with aluminium until now was to make it into forks, paper knives, and such like domestic trifles, although there had been many rumours as to the immediate adoption of aluminium for various military purposes, such as water bottles, cartridge cases, &c. It is, therefore, satisfactory to be able to chronicle the existence and successful trial of such a concrete piece of metal work as a second-class 60ft. torpedo boat, the hull of which is composed of 94 per cent. aluminium and 6 per cent. copper. This boat has been made to the order of the French Government by Messrs. Yarrow and Co., and, as compared to a steel boat of the same type, the scantling has been thickened about 25 per cent., in spite of which the total weight of the hull has been reduced about 50 per cent. The chief result of using the light material has been that a speed of 20½ knots has been obtained, in place of the 17 knots of similar steel boats. The alloy used by Messrs. Yarrow and Co. has a tensile strength of 14 tons to the square inch, and has a very high elastic limit. The price of the material for the hull and fittings varied from 3s. to 5s. a pound, and the metal used for this small boat cost over £1,000. All the aluminium plates and angles were imported from France.

A Necessary Contingency of the Telephone.—In the Recorder's Court at Belfast, last week, an action was brought by the National Telephone Company against Mr. John Robson, to recover the sum of £10, hire of a telephone and wire, which was alleged to be payable in advance, for the year commencing July 1, 1894. The defendant refused to pay, denied his liability to do so, and alleged that the telephone was a nuisance. The Recorder held that the Company was not entitled to maintain the action, and dismissed the case. In the course of the hearing of the action the following verbal encounter took place between Mr. Robson's counsel and the National Telephone Company's district manager:—Q. What is the object of the telephone? A. The object is to afford accommodation to people to converse with others at a distance.—Q. You are quite sure that it was a telephone you purported to supply to Mr. Robson? A. Quite sure.—Q. And not an alarum clock? A. Not at all.—Q. And I suppose it is one of the uses of telephone that it ought to wake you up in the middle of the night? A. It is one of the contingencies of the telephone that it would do so occasionally.—Q. Would it be a properly working telephone if it kept ringing all the day without being called upon at all? A. It would.—Q. And it would be a properly working telephone if, instead of hearing a communication from someone you wanted, you heard the private conversation of others? A. Yes, a perfectly proper telephone.—Q. And if you wanted to converse with someone about buying a house, you would not be surprised if you heard a concert in Dublin? A. Not at all.—Q. As a matter of fact, that is what the telephone was put up for? A. Oh, not at all; but it is a necessary contingency of the telephone.

Electric Traction at Havre.—On February 1, 1874, the town of Havre witnessed the "inauguration" of the first horse tramway in France. On the 25th ult. the first complete urban system of electric tramways in France was "inaugurated" at the same place, after having been at work since July. Judging by a five-column account, which appears in *La Semaine Electrique*, the ceremony seems to have been of an extremely pleasant character. The contractors concerned, viz., the Société Générale Française de Tramways and the Compagnie Française pour l'Exploitation des Procédés Thomson-Houston, issued no less than 400 invitations, supplied the invitees with a special train, "sumptuous" breakfast, luncheon and dinner, rides on ten electric cars all over the town, sleeping accommodation in the best hotel in Havre, finishing up with a special train back to Paris the next day. The chief technical item which seems to have struck the representative of our French contemporary dumb with admiration is the fact that the switchboard of the generating station, in spite of the size of the network which it serves, is only two metres by two metres, and contains but one single voltmeter and three ammeters. This severe switchboard simplicity by itself is sufficient to make us hopeful of the success of this tramway. Another item of some novelty in connection with this line is the fact that current is supplied by the local electric light company, although not from the lighting dynamos, since the company's system is alternating. The traction plant consists of three 4-pole 200-kilowatt 500-volt Thomson-Houston dynamos, rope-driven by Farcot-Corliss condensing engines. The rolling stock consists of 40 cars, 24 of which are driven by a single 25-H.P. single reduction motor, the balance having two such motors each. The network of the Havre Tramways Company is equal to 40 miles of single track.

Metropolitan Municipal Electric Lighting Stations.—The first week of the present month has been signalised by the opening of two municipal electric light stations on the outskirts of London. On Monday evening, the Hampstead Vestry station was formally "inaugurated," and on Wednesday evening the same ceremony was performed at Ealing.——The Hampstead Vestry's station is situated right in the centre of the district, and within a hundred yards of the boundary of the "compulsory area," which is of triangular shape, containing, from the electric lighting point of view, as fine a residential quarter as could be well imagined. Inside this area the Vestry supply is without a competitor; but there is a very profitable quarter adjacent to the "compulsory area," which is at present supplied by an enterprising local concern by means of overhead cables, which are a distinct disfigurement to the neighbourhood, and it is difficult to understand how the Company came to be permitted to erect such ugly excrescences. The Vestry plant comprises four Lancashire boilers fed by Bennis' mechanical stokers, one Willans-Siemens (alternator) combination of 300 H.P.; two of 150 H.P.; and one of 30 H.P., also two 25 H.P. 1,300-volt machines for the street arcs (Siemens). These machines, it should be mentioned, are in reality constant potential dynamos, but are made to give a constant current by hand regulation of the speed and by regulating resistances in the exciting circuit. The feeders (Siemens' concentric) feed transformers placed in pits under the pavement at 2,000 volts, the secondaries feeding into a three-wire network (Siemens' triple-concentric) at 200 volts. The station, which is located in the parish stoneyard alongside the London and North-Western Railway, has a nominal coal storage capacity of about 100 tons, and a water-tank of 10,000 gallons capacity. Some 1,300 lights are already connected to the mains, and about 3,000 more will shortly be ready to come on. Mr. R. A. Chattock, late of the Metropolitan Electric Supply Company, is in charge of the station.——The Ealing station, on the other hand, is situated at the extreme south of the district by the side of the sewage disposal and destructor station. The idea in locating the generating plant so far from the centre of supply is that the additional $C^2 R$ loss thus involved will be more than compensated for by the economy effected by making use of the waste heat from the refuse destructor "fume cremator," from which gases issue at a temperature, it is said, of between 1,200° F. and 1,800° F., and by using the sewage effluent for condensing purposes. It is expected that the total power obtainable continuously from the "cremator" will amount to about 50 H.P. The plant laid down is equal to the supply of 70 street arcs and 5,000 8-c.p. glow lamps, and comprises three Lancashire boilers, a 6in. cast-iron steam ring-main, McDougall mechanical stokers, and, for the public lighting, three Browett-Lindley vertical compound condensing engines, coupled direct to Siemens disc-armature 10 ampere 1,800 volts arc lighters running at 300 revolutions, and, for the private lighting, two Browett-Lindley engines, coupled direct to 60-kilowatt 2,000-volt alternators (40 ∿) and two similar engines coupled direct to 30-kilowatt alternators. The arc-light mains are concentric, lead-covered and armoured, and are laid directly in the ground; the lamps being of the Brockie-Pell type. The feeders, five in number, are also of the concentric type (Callender), and run to transformer sub-stations. The secondaries feed at 102 volts into a complete ring main.

THE CHEMICAL THEORY OF ACCUMULATORS.—III.

BY E. J. WADE.

In attempting to select from amongst the various theories of the action of lead storage cells the one which best corresponds to the facts of the case, two classes of evidence must be considered. Obviously there is the direct evidence afforded by analyses of the electrodes and electrolyte and quantitative determinations of the different compounds present at various stages of charge and discharge, while the corresponding physical changes in the electrical resistance of the cell, colour and appearance of the electrodes, and so forth should also furnishsome supplementary evidence. But beside these there is very important indirect evidence to be obtained from comparisons of the observed E.M.F. of the cells with that calculated by means of thermo-chemical data; and if, for any assumed set of chemical reactions, a real agreement can be shown between the observed and calculated values, strong *primâ facie* evidence is afforded that these are the ones actually occurring. It may be as well to state the law governing these calculations, and to show briefly both how it is derived and how applied, for very little information on this subject is to be found in any works on electricity.

The fundamental laws of electrolysis, first discovered by Faraday, are as follows:—

1. The quantity of any electrolyte decomposed by a current is directly proportional to the strength of the current and its duration; that is to say, to the whole quantity of electricity that passes through it.

2. The quantity of each electrolyte decomposed by a unit quantity of electricity is perfectly definite and constant, and is termed its "electro-chemical equivalent."

3. The quantities of different electrolytes decomposed by a unit or any other given quantity of electricity and in direct proportion to their chemical equivalents or combining weights.

The nomenclature now generally used in dealing with electrolytical matters was also devised by Faraday. He called the component parts (not necessarily elements, but oftentimes compound radicles or groups of elements such as SO^4, NH^4, and so on), into which an electrolyte is split up by a current "ions," those liberated at the electrode by which the current enters being "anions," and the electrode itself the "anode"; and those liberated at the electrode by which the current leaves "kathions," and the electrode the "kathode." Nearly all the tables and data relating to electro-chemistry and thermo-chemistry are given in terms of the gramme as the unit of weight, and the coulomb or ampere-second as unit of electricity; but otherwise calculations could equally well be made in terms of the more commercial units, the pound and the ampere-hour.

It follows, from the last of the above laws, that the weights of the component parts or ions into which any electrolyte is decomposed will also be proportional to their chemical equivalents. Thus 74·5 grammes of potassic chloride will split up into 39 grammes of potassium and 35·5 grammes of chlorine.

It also follows that, knowing the weight of any one element liberated by a unit or a given quantity of electricity, the electro-chemical equivalent or the weight of all the others can be determined. Tables giving the electro-chemical equivalents of the elements may be found in many works on electricity, and are arrived at by multiplying their chemical equivalents into the electro-chemical equivalent of hydrogen. According to the most recent determinations, the electro-chemical equivalent of hydrogen in grammes per coulomb is 0·00001038. Chemical equivalents or combining weights must not be confused with atomic weights; but, with a few exceptions, they are the atomic weight divided by the valency. For example, both the combining and atomic weights of hydrogen are 1; but while the atomic weight of oxygen is 16, and of aluminium 27·3, their combining weights are only $\frac{16}{2} = 8$ and $\frac{27·3}{3} = 9·1$ respectively.

The researches of Joule into the relations of heat to other forms of energy, and his determination of the mechanical equivalent of heat, rendered it possible to express the energy liberated or absorbed by chemical combinations or decompositions in mechanical, and, therefore, in electrical units; and in 1851 Lord Kelvin, then Sir William Thomson, applied his data to the reactions taking place in electrolytic and galvanic cells,and showed how the E.M.F. produced or absorbed could be arrived at from theoretical considerations. The work done in any electrolytical decomposition is evidently expressed by the product of the quantity of electricity passing through the electrolyte into the E.M.F. required to effect it. Therefore, $W = QE$, where W is the work in watt seconds or joules, Q the quantity of electricity in coulombs, and E the E.M.F. in volts. This work has, however, been absorbed in breaking up a certain portion of the electrolyte into two simpler substances; and if these recombine chemically to form their original compound, they will give out as heat exactly the same amount of energy as was previously taken up; but it can now be expressed in a different way. The "calorie," or unit of heat, is the amount of heat required to raise the temperature of one gramme of water 1°C. It represents the same amount of energy as 420 kilogrammetres, or 4·2 watt-seconds, and these constants are termed Joule's equivalent or coefficient. Calling H the number of calories liberated by the recombination of unit weight of one of the decomposed ions, and e its electro-chemical equivalent; then eH will be the heat generated by the recombination of as much of that ion as would be set free by one unit or coulomb of electricity, and JeH will represent the electrical equivalent of that heat in watt-seconds, J being Joule's coefficient.

If, however, Q coulombs of electricity were passed through the electrolyte, Q times as much of the ion would be liberated, and Q times as much energy set free on recombination, so that

$$W = QJeH,$$

and therefore $$QE = QJeH$$

and $$E = JeH.$$

Now it has been shown above that the electro-chemical equivalent of any element may be arrived at by multiplying its chemical equivalent c into the electro-chemical equivalent of hydrogen h; that is to say,

$$e = hc.$$

Therefore
$$E = JhcH$$
$$= 4·2 \times ·00001038 \times cH$$
$$= ·0000436\, cH.$$

Although this equation is primarily one for determining the minimum E.M.F. necessary to produce decomposition in an electrolytical cell, or, as applied to storage cells, for ascertaining the E.M.F. required to charge them; yet it is equally applicable to the calculation of the E.M.F. generated by primary cells, or the discharge E.M.F. of secondary cells. This being so, it obviously follows that, provided the chemical reactions occurring during charge and discharge are exactly the reverse of each other, the E.M.F. of these two operations must coincide; or, on the other hand, if they differ it necessarily implies that some corresponding chemical difference must also exist. Of course, losses of energy due to the internal resistance of the cells are not taken into account in any of the preceding remarks—it is E.M.F. and not P.D. (potential difference) that is being dealt with—and this must not be forgotten when applying them practically.

It is evident that the above formula is of no use unless the value of H is known for the reactions under consideration. It is only within recent years that it has been experimentally determined for any considerable number of combinations, Berthelot, Thomsen, and Naumann being the chief workers in this field; and it is only still more lately that their results have been available in English in a collected form. They may, however, now be found in a book on thermal chemistry by M. M. Pattison Muir,* while numerous other determinations, made since that work was brought out, are scattered through the *Journal* of the Chemical Society, and other publications.

In thermo-chemical notation the heat evolved by the union of two or more elements or compounds is expressed as the "heat of formation" of one formula weight of the resultant compound, and the precise nature of the reaction is indicated by writing the chemical symbols of the component parts with commas between them, the whole being enclosed in a square

* "Elements of Thermal Chemistry." 1885.

Digitized by Google

bracket. Thus, $[H^2,O]=68360$ means that the heat of formation of 18 grammes of water from 2 grammes of hydrogen and 16 grammes of oxygen is 68360 calories; $[H^2,S,O^4]=192930$, that the heat of formation of 98 grammes of sulphuric acid from hydrogen, sulphur and oxygen = 192930 calories; but $[H^2O,SO^3]=21320$ is the heat of formation of the same quantity of acid from water and sulphuric anhydride. The symbol Aq is used to indicate a large quantity of water, when solutions are being dealt with; thus, $[H^2SO^4, Aq]=17860$ stands for the heat evolved by largely diluting 98 grammes of strong acid, and $[ZnSO^4, Aq]=18430$ is the "heat of solution" of 161 grammes of anhydrous zinc sulphate. Some few compounds absorb heat in their formation, in which case the negative sign is written before the number representing the calories so taken up. For example, $[H^2O,O, Aq]=-23060$ indicates that the formation of 34 grammes of hydrogen peroxide by the combination of 18 grammes of water and 169 grammes of oxygen, in the presence of a much larger quantity of water, absorbs 23060 calories. The net result of a series of reactions involving the decomposition of some compounds, and the formation of others, is written in the form of an alegebraical equation, those bodies that are decomposed having the negative sign placed before them. Take, for example, the action occurring between zinc and sulphuric acid, in which zinc displaces hydrogen, zinc sulphate being formed and hydrogen sulphate decomposed. The ordinary chemical equation for this reaction is

$$H^2SO^4 + Zn = H^2 + ZnSO^4.$$

The thermo-chemical equation will be

$$[Zn,SO^4,Aq]-[H^2,SO^4, Aq]=145260-107530=37730,$$

and represents the heat liberated by the formation in solution of 161 grammes of zinc sulphate at the expense of 98 grammes of dilute hydrogen sulphate.

In the case of a double reduction, such as the action of dilute sulphuric acid on litharge, two new compounds are formed and two decomposed, thus:

$$PbO + H^2SO^4 = PbSO^4 + H^2O,$$

and the thermo-chemical equation for these reactions is

$$\left.\begin{matrix}[Pb,SO^4]+[H^2,O]-[Pb,O]-[H^2,SO^4, Aq]\\ 112970+68360-50300-107530\end{matrix}\right\}=23500.$$

The fact that heats of formation are expressed in terms of the formula or atomic weight of the resultant compound and its component parts, renders their application to calculations of E.M.F. very easy, for the figures throughout directly represent (c H $\times$ valency), and therefore

$$E=\frac{\cdot 0000436\times \text{heat of formation in calories}}{\text{valency}}.$$

The heat of formation is, of course, understood to be the net result of the whole of the electrolytic reactions taking place in the cell. Now almost all battery equations are bi-valent—that is to say, they are expressed in terms of the transfer of two atoms of hydrogen or its equivalent, and therefore

$$\frac{\cdot 0000436\times 46000 \text{ calories}}{2}=1 \text{ volt},$$

and $$E=\frac{\text{heat of formation in calories}}{4{,}6000};$$

or, putting this in words, a net heat of formation of 46,000 calories corresponds to 1 volt, and the E.M.F. of a set of battery reactions may be obtained by dividing their resultant heat of formation by 46,000.

Since Thomson's law was first enunciated a number of instances have from time to time been brought forward, for which it does not appear to hold good—in fact, the calculated E.M.F. of lead storage cells has never yet been brought into satisfactory agreement with the observed values—and it has been argued, therefore, that determinations made by its means have very little weight either one way or the other. It must be remembered, however, that the application of this law is not always so simple as may at first sight appear; obscure effects due to variations in degree of concentration or dilution, allotropic modifications and alterations in the physical state of the substances taking part in the reactions and so on, all have to be taken into account; and the data bearing on such points is often vague and meagre, and perhaps not very accurate or reliable. If, after all allowances have been made, larger discrepances still exist it seems safer on the whole to conclude either that some further modifying cause has been overlooked, or that the assumed chemical reactions are not those that actually occur, rather than to at once proceed to impugn the accuracy of the law itself.

Helmholtz has shown that the formula will need a temperature correction when applied to galvanic or electrolytic cells, whose E.M.F. varies, as the temperature changes either directly or inversely. No very exhaustive or concordant determinations of the temperature coefficient of lead storage cells appear to have been carried out; but from some made by Mr. Preece in 1883,* it is evident that it is at any rate very small, and not nearly sufficient to necessitate the correction being taken into account.

The chemical changes that occur during discharge have received far more attention, and been the subject of far more controversy, than those of charge, partly because it is the period in a cell's working that is of most importance from a practical point of view, and partly because it is then that the nature of such changes is most easily investigated. The E.M.F. corresponding to the various theories of their action during discharge can now be calculated from thermo-chemical data, according to the methods just laid down. The actual E.M.F. against which it has to be compared is that that obtains during the normal discharge of a cell; the abnormally high E.M.F. that exists for a short time after the cessation of charging—if fully charged—and the rapid fall of E.M.F. that takes place when over-discharged, both being due to abnormal reactions, which must be considered separately. It is a matter of common knowledge that the normal E.M.F. of a cell with ordinary strengths of acid is at least 2 volts during the earlier portions of the discharge, falling slowly to, say, 1·9 volts towards the end. It is true the potential difference may drop to 1·85 volts, or even lower, before the rapid falling off sets in; but the internal resistance of the cell has to be allowed for, and this is a fast increasing quantity at this time.

The first theory to consider is that which assumes that the metallic constituents of the electrodes take no part in the reactions; but that the whole of the energy of the cell is derived from the recombination of the oxygen and hydrogen occluded in their pores. The electrolytic equation may be represented thus:

$$PbO^2O \mid H^2O \mid H^2Pb = PbO^2 \mid OH^2 \mid OH^2 \mid Pb,$$

and the thermo-chemical equation:

$$[H^2,O]=68360=1{\cdot}485 \text{ volts}.$$

The next theory supposes that both electrodes are attacked with the production of monoxide or litharge, water still being the electrolyte, thus:

$$PbOO \mid H^2O \mid Pb = PbO \mid OH^2 \mid OPb,$$

and the thermo-chemical equation,

$$\begin{aligned}[Pb,O]-[PbO,O]&=50300-12000=38300\\ &=0{\cdot}82 \text{ volt}.\end{aligned}$$

Next it is allowed that sulphuric acid must be the real electrolyte, and acts on the negative with the direct production of lead sulphate; but the positive is reduced to monoxide as before, so that every molecule of acid consumed is replaced by a molecule of water, thus:

$$PbOO \mid H^2SO^4 \mid Pb = PbO \mid OH^2 \mid SO^4Pb,$$

and the thermo-chemical equation,

$$\left.\begin{matrix}[Pb,SO^4]-[H^2,SO^4,Aq]+[H^2O]-[PbO,O]\\ 112970 \quad - \quad 104630 \quad +68360 - \quad 12000\end{matrix}\right\}\begin{matrix}=64700\\ =1{\cdot}4 \text{ volts.}\end{matrix}$$

Although for the sake of simplicity the electrolyte is assumed to be a very dilute solution of sulphuric acid, H^2SO^4,Aq, the figure for the corresponding heat of formation is calculated on the basis of a very much stronger solution ($H^2SO^4,9H^2O$, which is rather more than one part of acid by weight to two of water, giving a solution whose specific gravity would be about 1·280) in order to give the resultant E.M.F. the highest value possible.

* *Proc.* Royal Society, 1883, Vol. XXXV., page 250.

Digitized by Google

This equation also represents the E.M.F. according to the views of those who admit that lead sulphate is also formed at the positive electrode, but consider it is merely the result of a secondary reaction between the monoxide and the sulphuric acid, which would be entirely dissipated as heat without furnishing anything towards the E.M.F. of the cell:

$$PbO + H^2SO^4 = PbSO^4 + H^2O.$$

Various other theories have been propounded from time to time regarding the reduction of the lead peroxide at the positive electrode. It has been suggested that it is first reduced to metallic lead, and then sulphated by local action; while Mr. Fitzgerald has maintained that it is only reduced to sesquioxide (Pb^2O^3) before sulphating. As, however, these theories have never been widely held, and have very little, if any, evidence to support them, it is not worth while going into the details of their thermo-chemical reactions; but if worked out it will be found that, like those given above, the calculated E.M.F. falls far short of what is required in every case.

(To be continued.)

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(Continued from page 481.)

There has always been a certain fascination about the application of electric power to coal-cutting and rock-drilling. It is not difficult to appreciate this feeling when one has had some experience of coal-getting. Indeed, it has been felt for a long while that a mechanical means of hewing coal was desirable from all points of view. Yet, strange to say, the problem has presented so many difficulties that its successful accomplishment on a large scale still belongs to the future. Of course coal has been got by mechanical means in isolated cases for a long time past, and the difficulties are well known.

These may be regarded under two separate heads, each of considerable weight. The first refers to the mechanical side of the question, and hence properly belongs to the present discussion. The second relates to the system of working and the general management of mines, and cannot be treated here at length. But reference must be made to some of the difficulties thrown in the way of mechanical coal getting by the men and the masters. The use of a coal-cutting machine may seem to be simply a question of the price of coal hewn by it in comparison with the cost of hand-hewn coal. This is undoubtedly the case. But the cost of machine-won coal is at present necessarily based on figures resulting from the use of one or two machines instead of on the basis of a dozen worked on "faces" specially laid out for the purpose. It should be noted that the cost of the prime power for two or three machines is practically as great as that required for a dozen, and the system of mains need not be proportionately increased for the larger number, because the power does not increase in direct proportion to the number of machines, it not being possible to keep them all running at the same time. It is important, too, that machinery should be run as nearly continuously as possible, which suggests the employment of several shifts of men. And this is only possible, even if the men's union permit it, when the conditions are such that the coal can be carried away sufficiently quickly. In the majority of faces, as arranged to-day, this is impossible, and a machine cannot be kept at work continuously for even a shift of eight hours; so that the theoretical output of the machine is never reached from causes which are quite independent of the working capability of the machine. This points to a coal cutter of smaller capacity than those now in use—say a machine which would hole from 5 to 10 yards an hour, working under normal conditions and allowing the necessary time for clearing away the coal. Up to now the aim has been rather to produce machines which, under favourable circumstances, will cut from 20 to 40 yards of face per hour. But a very casual inspection of a coal mine will demonstrate that such a rate cannot be maintained for any length of time, simply from the difficulties of clearing away through gates two chains apart, even neglecting for the moment the difficulty of keeping the face clear from falls of roof during the time necessary for removing the coal.

If mechanical coal-getting is to be carried out on a large scale with the long-wall system, it will be necessary to modify the number and position of the gates in order to increase the facilities for clearing away. The question belongs to mining managers, and not to electrical engineers; and this is, perhaps, one of the chief reasons why mechanically-driven coal cutters have not made as much progress as their undoubted utility appears to warrant. A colliery is being opened out at the present moment near Eckington, in which the whole of the work will be done electrically, even to the driving of the fan. The coal will be worked on the pillar and stall system by Jeffrey coal-cutters. This undertaking is due to American enterprise, and will be watched with the highest interest.

It does not lie in the province of the present work to discuss the question of machines *versus* hand coal-getting. But it may be remarked that one of the best electric coal cutters, with two men to work it, will easily hole as much as from 20 to 30 hewers; thus largely reducing the number of men required below ground. And since the number of accidents bears probably some proportion to the number of men employed, the introduction of machinery should have the effect of largely reducing the loss of life.

The number of mechanical principles applied to coal-getting machines is astonishing, and the ingenuity displayed by many inventors who evidently are not in close touch with the principles of mining is equally surprising. Every conceivable method of cutting, drilling, boring, shearing, or picking coal has been designed, on paper at least, and many of them have been applied to more or less practicable machines. The earliest attempts were made in the direction of a mechanical pick. As

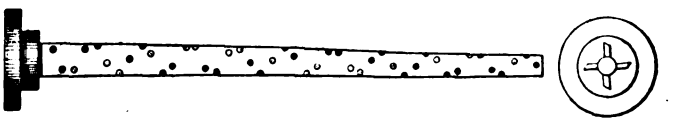

FIG. 119.—Goolden-Atkinson Cutter Bar.

might be expected, the pick, with the man at the back of it directing each blow, did much the better work, and the method was soon dropped. The drill and the circular saw have given the most successful models upon which to work out a cutter, and hence a variety of machines embodying these principles.

The machines which have survived the initial stages and give some hope for future success are divisible into three main classes:—

(*a*) Bar cutters.
(*b*) Rotary wheel or disc cutters.
(*c*) Drills.

Under the first head may be included all those machines which have a cutter bar revolving either at right angles or parallel to the face of the coal. This type has so far proved the most successful in this country and in America, the best known being the Goolden-Atkinson bar cutter of English invention, and the Jeffreys machine of American origin.

The essential feature of the Goolden-Atkinson machine is a tapered rotary bar, which is fitted with a series of cutters driven into tapered holes. They are arranged in a spiral form, the object being to clear out the cuttings and prevent the jamming of the bar. The shape, size, and general arrangement are the result of long and careful experiment by Messrs. Llewellyn and Claude Atkinson, the staff of Messrs. Easton, Anderson, Goolden and Co., and the Electric Coal Cutting Corporation. The cutter bar (*see* Fig. 119) is usually geared to the armature shaft by a pair of cast steel double helical wheels running in oil, and the cutter makes 300 to 500 revolutions per minute, depending on the material being cut. The motors are always wound in series, and hence the speed varies inversely as the resistance which is exactly the best condition for work of this kind, since it prevents undue shocks to the motor, and tends to keep the power absorbed within safe limits. The motor is thoroughly protected from mechanical injury either from falls of

* All rights of reproduction reserved.

Digitized by Google

roof or sides, and the armature and commutator are fitted into a dust tight and flame tight compartment of dimensions as small as consistent with the safe and effective handling of the brushes. The cutting mechanism as a whole is made to swing through an arc of rather more than 90deg. on the turntable which carries it (*see* Fig. 120). This gives facilities for shifting the machine from point to point in the mine, and also enables the bar to cut its way into the coal until it is at right angles to the face and ready for holeing. Fig. 120 gives a view of the machine as arranged for work. In the early machine of this class the coal was always picked out to give the bar a start. Since the bar has to be carried by bearings it may be thought that coal cannot be cut level with the floor by the bar type of machine; but this difficulty is successfully met. By arranging the seats of the turntable at a proper angle, and causing it to revolve in an inclined plane, the makers contrive to keep the from the faces, leaving them ready for the machines. The system on the whole has worked well, and if it were not for the difficulties already referred to, the machines would turn out a much larger tonnage and, of course, return a larger interest on the capital outlay.

The experience of the Corporation, whilst it has demonstrated that nearly every mine, working long-wall, can be successfully operated by electric coal-cutting machines, has also brought into further prominence the essential difference between hand and machine working, and the great difficulties of getting not the men but the owners and managers to appreciate the difference, and to lay themselves out to apply to mines the discipline and regularity obtaining in manufacturing industries.

A modification of the Goolden-Atkinson machine has lately been introduced by Mr. Frederick Hurd, who for some years was

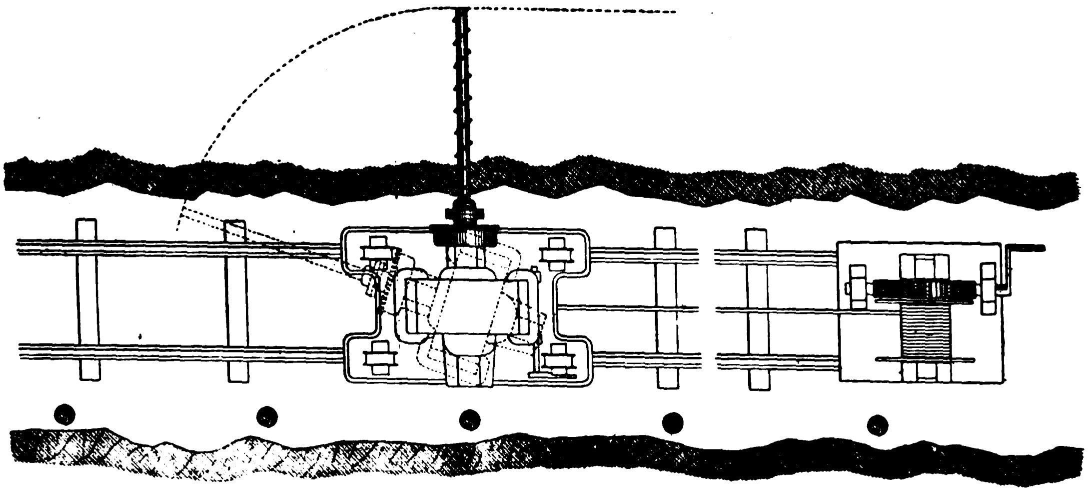

Fig. 120.—Goolden-Atkinson Coal Cutter. Method of Working.

bar nearly horizontal and below the level of the rails when at right angles to the face in the cutting position, and yet to lift over the rails when turned parallel to the face. In this way a flooring of regular slope is made at every cut, and forms the floor for the rails during the next cut. It is not found necessary to level the floor in the majority of cases, although when cutting in coal it may pay to do so. The feed is made by a hand winch as in Fig. 120, or it is worked automatically from the motor shaft. The author believes that hand feeding is found to be the more satisfactory with this machine.

The Electrical Coal Cutting Corporation have for some years been working coal at a contract price per ton hewn or per linear yard undercut to a specified depth. They supply the whole of the plant and the men to work the machine, while the colliery proprietors find the labour for clearing away the coal on the staff of Messrs. Goolden and Co. No particulars of its performance have yet been published. There is a scoop built at the back of the bar to assist the clearing of the cuttings from the hole. This may or may not be an improvement, experience alone can determine. There are also some interesting devices for ventilating the motor and safe-guarding it against the risk of exploding gas. These consist of an elaborate system for circulating fresh air under pressure along the conductors, which are encased in pipes for the purpose, and through the interior of the motor, the starting resistance, and switch-board boxes, &c. The object in view is, of course, most desirable; but the expense necessary to execute the system described in Mr. Hurd's patent specification is probably too costly for ordinary requirements.

(To be continued.)

A LEISURELY LIGHTNING FLASH.

After describing the recent accident at Aldershot, where a captive balloon was struck by lightning, the *Daily Telegraph* proceeded to discuss the historical experiments of Benjamin Franklin and Richmann with greater scientific accuracy than might be expected from a daily newspaper. It fell, however, into a pardonable error, and, after quoting Prof. Tait, said: "A flash of lightning lasts, roughly speaking, about the millionth of a second, as is proved by the fact that the most rapidly moving bodies appear to be at rest when illuminated by it. There is no doubt that if it could be made to endure one-tenth of a second, lightning would appear to be one hundred thousand times more brilliant than moonlight." This might have passed without comment six or eight years ago, but modern photography has shown that the quiver which is often seen in a flash of lightning is due to an actual persistence of the flash. Not, indeed, in a continuous stream, but a succession of flashes closely following each other in precisely the same path. We have a very remarkable negative before us, of a flash of lightning; but efforts at making a reproduction of it to place before our readers have not been very successful. Mr. Eric Crawley had a "Frena" camera in his hand during the thunderstorm of July 13, 1894, in broad daylight, and a vivid flash occurred; he quickly pointed the camera at it, and snapped the shutter, giving $\frac{1}{20}$ sec. exposure—a most useless waste of a film if the *Daily Telegraph* is right. The negative shows one faint forked flash vignetted off on one side, and a broad, ribbon-like flash, wider at one end than the other. The average width is about $\frac{1}{8}$th of an inch. The negative is about 3in. square. Assuming the angle of the lens is about 45deg., the angular width of the flash is nearly 2deg. or four moon breadths. One edge is more intense than the rest, but a powerful lens shows no longitudinal markings. There are, however, numerous transverse markings, some of which are reproduced in the engraving (Fig. 1), which has, with some difficulty, been made from this interesting photograph. The absence of longitudinal markings shows that, if a rapid succession of flashes was taking place, they were so numerous that they left no individual traces; and it is difficult to believe that the flash was in any sense continuous. The presence of fine transverse markings is probably due to a fine

Digitized by Google

zigzag structure. This structure is shown, of course, on an entirely different scale, in Fig. 2, which we reproduce from Prof. S. P. Thompson's Paper on Influence Machines.* In this case the zigzags are no doubt due to the jumping of the discharge from dust particle to dust particle, like stepping stones. A large zigzag in a lightning flash may be attributed to differences of temperature or rain-drop density in the path,

Fig. 1.

but it is difficult to account for fine irregularities. Other photographs of lightning flashes have been reproduced in *The Electrician*, Vol. XXI, p. 699 and Vol. XXIII, p. 227. The remarkable feature of this photograph is, that at least a tenth of a second must have elapsed between the commencement of the flash and the attempt to direct the camera towards

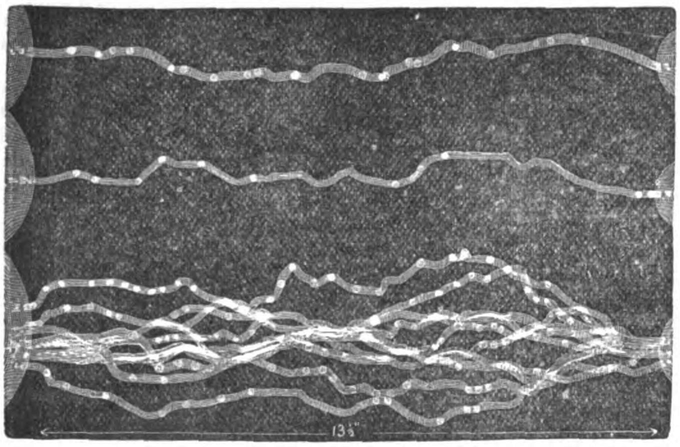

Fig. 2

it. How long it took to do this and to snap the shutter is impossible to guess. The great width of the photograph shows that the camera must have been in motion, and the intense edge, being on the same side in each case, shows that probably at the end of the exposure the camera was practically stationary.

* Society of Telegraph Engineers, May 31, 1888.

NEW AYRTON-MATHER GALVANOMETER.

Mr. R. W. Paul is bringing out a modified pattern of D'Arsonval galvanometer for laboratory and test-room work, where compactness and portability are not the chief essentials. In this instrument the working parts are more accessible and open to view than in previous patterns. The illustration (Fig. 1) shows the galvanometer mounted on a brass base, with levelling screws, and a circular level carrying a tripod on which the magnet is clamped. An insulated socket, connected to one terminal, is fixed beneath the poles of the magnet, and carries a vertical brass tube, cut away in front for the greater part of its length. The suspension strip is fixed to a torsion-head in the upper part of the tube, but is not screwed to it directly ; it first passes through a fine hole in a thin bronze spring, which yields when the instrument is set down roughly, and prevents breakage of the suspension. The lower end of the tube is fitted with an ebonite plug, through which a brass stud is screwed, whoes lower end makes contact on an insulated spring attached to the remaining terminal. This stud is slotted at its upper end,

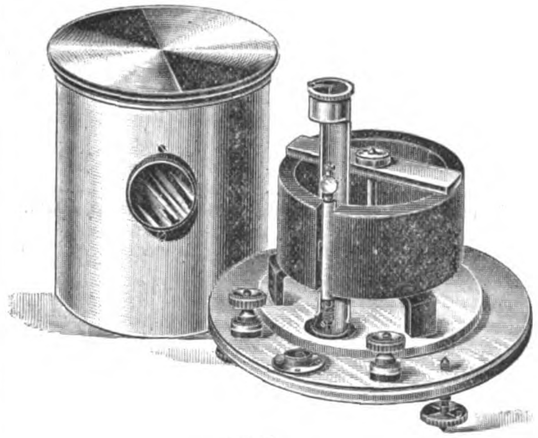

Fig. 1.

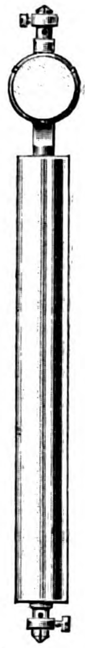

Fig. 2.

and fitted with a collar and set-screw to close the slot ; similar clamps, seen in Fig. 2, are provided at the extremities of the tube containing the moving coil, soldered contacts on the coil tube may be provided for those who prefer them. The cover is made with a lid which can be lifted off to get at the torsion-head and set the spot on the scale.

THE ELECTRIC BRAKE IN PRACTICE.*

BY ELMER A. SPERRY.

(*Concluded from page 644.*)

The current required to be developed to stop a car, when no other braking apparatus is used, is found to be only a fraction of that required to accelerate the car in the same interval. This may be easily illustrated by the lines in diagram 5, A being the electrical energy applied in a given acceleration ; B the resulting mechanical energy stored in the car after deducting all the wastes in the motor, and between the motor and the momentum ; C the average mechanical energy in the car at the time of applying the

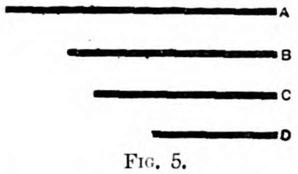

Fig. 5.

brake ; D being the electrical energy required to be developed for retardation after the efficiency losses have all been provided for out of the quantity C. Thus it will be seen that the so-called efficiency losses act in a two-fold sense, between A and B and between C and D, to reduce the amount of current required to be generated for braking purposes.

As to the effect of the electric brake on the total temperature of the motor the following experiments were made. A car and trailer were operated over the line in regular service 41·1 miles without the brake. The temperature of the atmosphere was noted every half-hour during the test, and the temperature carefully taken of all parts of the motor at the end of the run. The succeeding

* Abstract of a Paper presented at the meeting of the American Institute of Electrical Engineers, September 19th.

Digitized by Google

day a similar run was made with the same trailer over the same track and in the same length of time, but with the electric brake in use, braking direct on the simple local circuit without brake magnets. The difference in the average atmospheric temperatures during the two days was six and one-half degrees, and the difference in the average temperature of the motor parts was seven degrees, making only a difference of one-half of one degree Centigrade as the total increase of temperature from the use of the brake. Observations in reference to the heat in the reostat were made, although no temperatures were taken, and no difference could be observed in reference to the heating of this portion of the equipment. The explanation will be found in the comparatively small amount of current as seen above, and the relative infrequency of its application, and short duration at the time of each application. The following wattmeter readings have also been taken :—

——	First trip.	Second Trip Trailer.
Reading of wattmeter, leaving Lake View ...	392,538·9	392,542·25
Reading of wattmeter, end of round trip ...	392,542·25	392,547·1
Number of full stops	55	53
Number of slow-ups	42	37
Time	1:40	1:35
Difference in reading	3·35	4·85

Constant of wattmeter equals "22" : total watts both trips, 180·4.

Diagram No. 6 indicates the connection of the wattmeter in the circuit.

Automatic resistances were even at one time used in the endeavour to relieve the motorman of *all* responsibility in connection with the

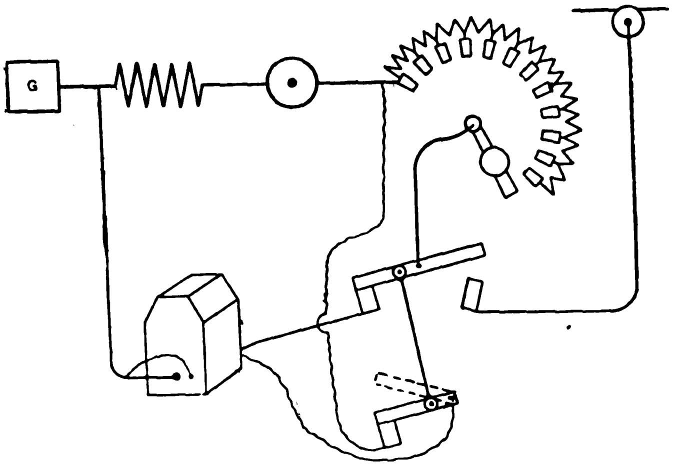

Fig. 6.

control in applying the brake, but superlative simplicity was found to be much more desirable than the superlatively automatic, and the automatic devices were seen to be entirely unnecessary, the apparatus as at present constructed being of great simplicity.

The diagram of the braking current in Fig. 4 (see *ante*, p. 644) shows the automatic decrease in the intensity of the brake application so desirable with the decreasing speed referred to above. As the speed decreases, the generator runs more slowly and consequently produces less and less current.

With this style of brake, the life of the wheels is increased from two to three-fold, thus affording a saving in the item next in cost to the electric maintenance itself, to say nothing of the entire saving in brake shoes. This is emphasised in the fact that the brake shoes are being constantly besmeared with sand and grit thrown from the wheels, and, when in this condition, they are brought against the wheels with the tremendous pressures noted above. A better method could hardly be devised for reducing both wheel and shoe. We little realise the great number of brake applications necessary in a day's run. Careful record has been kept of this point, giving in three days an average of 1,377 brake applications for a run of about 164 miles.

Another interesting feature in this connection is that a flat wheel from skidding is an impossibility. It will readily be seen that should the wheels stop, the generator connected with the axles ceases to produce current, and none, therefore, exists to farther apply the brake, and though they may be sliding forward on the rail, yet the wheels continue to rotate more or less, and constantly present new surfaces for the sliding contact.

The braking action is two-fold and is especially efficient. The rotating armature of the motor, instead of tugging ahead by its momentum, is itself pulling back and more or less powerfully braking the car through the gears by the retarding effort of the magnetism of its field while generating the braking current. The power required, therefore, to perform this work is taken from energy of the moving car which it is desired to destroy ; not only is the car thus retarded, but the electric brakes arrest the motion of the wheels direct, with a force that is remarkably powerful and under perfect control of the motorman.

Two forms of braking magnets are used, one for winding up a brake chain usually employed in connection with the trailer, and another for directly arresting the motion of the axles, one magnet only being used in connection with each axle. These magnets are truck-mounted, not an ounce of their weight being directly on the axle, and are so supported that their gravity acts to automatically retract them from the brake face, the latter showing the link standing out of the vertical. The brake face is automatically lubricated to a slight degree, receives a high polish and does not cut or rapidly wear. The brake is noiseless in its operation. Its crescent form accomplishes important technical functions and also eliminates the necessity of pulling off a wheel for its attachment, removal, or inspection. Its face is *solid unbroken metal*, with no grooves or interstices for catching grit or sand, which in part explains the absence of wear above referred to. The brake magnet is practically indestructible, a few turns of stout wire constituting its one coil entirely enclosed and sealed in metal. No harm nor moisture can reach it. As to moisture, it is immaterial, as the E.M.F. at which it works is extremely small, seldom reaching six volts. The lubricator for the brake surface is dry, not sticky or adhesive, and does not gather sand or dirt and retain it upon the braking face. No mechanical pressures whatever are employed to arrest the car, and hence no strain or shoulder-wear comes upon the journals. In constructing the brake magnets their proportions, and the arrangement of the magnetic circuits received considerable study. It was during some preliminary experiments that an unexpected phenomenon was noticed ; namely, that the retarding effect, when speed is an element, is very much more than would have been expected from the co-efficient of friction due to magnetic attraction or adhesion, this latter being a known and definite quantity. Further experiment, made to ascertain the cause, showed it to be due to Foucault or eddy currents set up in the masses. The conditions and structure of the brake magnet were, therefore, varied in a number of particulars, especially such as would be expected to give the greatest result in Foucault currents produced. The result was immediately successful. It was found that the retarding effect of the brake magnet is due very much more to the generation of these currents than to the direct effect of the coefficient of friction resulting from direct magnetic adhesion, the amount of which, I find, can be relied on accurately when employed by itself. Some of the forms of brake magnets experimented with were provided with numerous poles of opposite polarity, which were worked upon three different kinds of armature, two of which had radial teeth of different number relative to those in the magnet, and one being a plain disc armature. The toothed armature, while it causes a series of sudden jerks and is also unsatisfactory in the total retardation resulting from a given input is found also upon rupture of the magnetic circuit to impart to the magnet coil certain counter E.M.F.'s which materially cut down the current supply and thus the capacity of the device. A magnet formed of a continuous disc with an annular groove sunk in its face is found to give very satisfactory results, but is much heavier and requires an armature twice as heavy for a given number of lines as the double circuit magnet. Furthermore, the relative rotation between such a magnet and its armature affords no point in the masses where the lines are interrupted or changed, and the Foucault currents, or reactionary effect set up, is very much inferior to those in a magnet where a gap or cessation of magnetic stress is easily produced. As a result of these investigations the crescent form has been adopted, the opening in the crescent giving the effect referred to, as well as affording an excellent method of attachment and removal of the brake magnet, and at the same time supplying a gap for easily reaching the face for inspection and lubrication. The belief that the extra retarding phenomenon is that of Foucault or other eddy currents is borne out by the fact that a conducting lubricant, such as graphite, is found to considerably increase the effect ; also metal filling between the polar faces is almost indispensable for the best result, while at the same time effectually protecting the coil from all damage. These observations would seem to indicate that the eddy currents, however produced, circulate in both masses near the surface, and traverse back and forth across the air-gap whenever ample provision is made to allow them so to do. The practical value of the combined action of all these forces in increasing the retarding effect results in necessitating but a small magnet, and a smaller current expenditure considering the work performed.

By reference to Table III., the result in retardation gained through the eddy or other currents may be plainly seen, column A

Digitized by Google

indicating the retarding effect which should be expected from a friction coefficient of 10 per cent. between the lubricated surfaces due to magnetic attraction of the lines actually circulating, and column B indicating the values of retardation actually obtained on the dynamometer.

Table III.

Amperes.	Volts.	"A." Pull due to magnetic adhesion or traction. Friction coefficient 10 per cent.	"B." Pull on brake chain obtained. Graphite lubrication.
		Lb.	Lb.
5·0	1·0	7·6	125
9·0	1·8	18·3	300
9·5	1·9	36·4	608
15·0	3·0	121·0	1,976
16·0	3·2	149·0	2,432

35·5	7·3	214·0	3,500
41·0	8·5	223·0	3,650

The assumed values are based on a traction of 28·26lb. per square inch for 45,000 lines per square inch, being the assumed values at the knee of the curve easily recognised as occurring between 16 and 20 amperes in the table.

As to the arrangement for application and control of the brake by the motorman, about a year ago the following appeared from the hand of the writer :—

"Considering the inexperience of the operator and the responsibility which at times well nigh overwhelms him, I think that, as engineers, we should be willing to set a very high mark to be attained in the ideal brake for electric street railway service, namely, the use of but a *single controlling handle for everything;* starting, accelerating, retarding and braking the trailer, or trailers and all. Let the motorman have nothing to think of except one handle, and two-thirds of the accidents now occurring will be prevented. Let this handle require no more exertion in its operation than the present controlling handle. Let the motor man fulfil his function with as little physical exertion as possible ; he will then have a greater reserve for mental application when necessary. A motorman required to exert an enormous amount of brute force, constantly grinding at the brake, has but little life left to apply in case of emergency. I agree with a prominent writer on this subject, where he says that a multiplicity of handles is fatal in time of emergency."

At the time the above was written, equipments controlled as therein set forth—namely, by the use of a *single controlling handle for everything*—had been in operation for upwards of a year. The methods employed for accomplishing this have been varied, but the form most in use at the present time is where the resistance contacts are employed in a two-fold manner ; the controller handle is made to operate back and forth over the same contacts for controlling both the application of the current to the motor and braking the car.

The smoothness of even a sudden stop by the electric brake is as though the car was running into an air cushion.

It will thus be seen that the brake is automatic and does its work without any special act or even the knowledge of the motorman. He simply "works a single handle" back and forth and electricity "does the rest." Suppose the motorman wishes to stop his car, he turns off the current by simply swinging the lever over to the right. This operation is made to automatically convert the motor into a special dynamo for generating currents at very low speeds, and also simultaneously to cut off all connection with the trolley current. The brakes are then applied by simply swinging the handle back over the path it has just traversed ; the farther it is swung to the left the stronger the brakes are applied. The act of releasing or letting off the brakes again automatically re-establishes connection with the trolley and reconverts the dynamo into a motor. The same rheostat and contacts are applied to control the motor while running the car, and also to control the slight amount of current generated by the transformed dynamo which is sufficient to brake the train.

The motorman cannot turn on the current before the brakes have been released, nor can he apply the brakes before the current has been turned off. This is a result of construction, and constitutes a feature of merit in the new electric brake, effecting an economy in current and a saving in wear and tear. Freeing the conductor of all care in this connection, and leaving the braking of the train—including trailer or trailers and all—solely in the hands of the motorman by placing at his command a power with which he may with the utmost ease accomplish his task, constitutes an important advance in the art of control of electric railway equipment.

It has been found that the electric brake is practically incapable of abuse by any motorman, an advantage which never before has been attained in any power brake, due to the fact above named, that no amount of over-application can cause flattening of the wheels, or any harm whatever to any part of the equipment through their locking and skidding.

Operating the brake in this manner, it will at once be seen that the system is one of the utmost certainty of operation, surer even than the hand brake, air or other power brake, from the fact that every time the car runs, the motor, which is depended on for the braking action, receives a test, and its fitness and capacity for the next brake application is constantly being demonstrated. On the other hand, the motorman never knows whether his hand brake is sure to operate when called upon for the next application. An accident came under the observation of the writer on Case Avenue hill, in Cleveland. Here the last hand brake application was successful in every way ; but before the brake was called into action again a nut dropped off from a brake rod upon the truck, rendering the brake useless. The motorman continued to wind on his brake staff, and before he realised what the trouble was, his car was going at a tremendous speed into a short curve at the foot of the hill. There were a number of casualties and also six demands for damages as a result. With the air or other power brake this liability to failure is increased in direct proportion to the complexity and number of parts.

The advantages found to result from the practical use of the electric brake as compared with former brake systems ; its qualities as an accident preventer, as well as its general commercial value, may be recapitulated as follows :

1. The certainty of its operation.
2. The enormous power at instant command and under perfect control.
3. The absence of all power absorption at moneyed cost from the central station.
4. Its high efficiency, being far superior to compressed air ; amply proven in numberless instances where electricity has replaced air. (The air requires a direct application of energy, amounting to an immense aggregate power-absorption during the day from the central station ; the working parts of the air machinery are attached to the car axles, and require a large quantity of energy, not only while compressing, but at other times as well.)
5. Its extreme simplicity.
6. Observe saving in wheels, two to three-fold.
7. Entire saving in brake shoes.
8. Lubrication of brake face ; very little wear of either wheel or magnet.
9. Absolute silence of operation and release. (No hissing to frighten horses in streets.)
10. The low E.M.F. at which it operates.
11. The ease of its application and control.
12. Conserving strength, and prolonging the usefulness and life of the motormen.
13. The smoothness of its operation.
14. Cannot cause flat wheels.

Electric Radiation.—In a recent number of *Wiedemann's Annalen*, Dr. Zehnder describes the results of some measurements made with the large prism lately described in our columns. He finds, by two methods which agree within narrow limits, that the index of refraction for the asphalt used is 1·93 for electric waves about 70 cm. long. Hertz found that of pitch to be 1·69. The tinplate shields which had to be used to cut off the rays passing by the prism had considerable influence on the angle of deflection. The reason is that two tinplate shields 80-100 cm. apart, with their plane perpendicular to the direction of the waves, themselves deflect the rays through an appreciable angle, and cause phenomena of diffraction. A diffraction-grating made of several strips of zinc sheet 200 cm. long and 33 cm. wide, enabled satisfactory determinations to be made of the angle of refraction δ; from which together with the width of grating $b = 80$ cm. the wave length λ could be calculated from the formula $\lambda = b \sin \delta$. The average value $\lambda = 69{\cdot}4$ thus found comes fairly near to the value determined by Boltzmann's method. The author also finds that the primary reflector emits a bundle of rays capable of being separated into an electric spectrum, but with his present means could only trace waves from 67·4—73·3 cm. long. He thinks, however, that Sarasin and De la Rive go too far in imagining the radiation contains rays of *every* wave length.

STEEL-PLATE PORTRAITS

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; and Dr. Heinrich Hertz, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

WATER-POWER IN GREAT BRITAIN.

The problem of the utilisation of the water-power of this country is one which has a great fascination for the minds of those who imagine they see in it a means of obtaining energy for nothing, and in the electric current a means of transmitting that more than cheap energy to an indefinite distance. But, before the steady arithmetical gaze of an engineer, these glorious qualities shrivel to a finite magnitude of very limited dimensions; and it is perceived that neither can water-power ever be obtained for nothing, nor can its useful effect be transmitted electrically to more than a certain distance without the serious and effective competition of other sources of power. Of the two sides of the water-power problem—namely, where to use it and how to use it—the former is by far the most difficult, though at the same time the one least recognised. Every babbling brook is the equivalent of so many 8-c.p. lamps, in the eyes of some people; and every out of the way waterfall is a thing whose energy is to be hurried as far as possible along a cable to the haunts of men. It is a very intricate matter, in these little British Isles, this question of where to utilise water power; and, if even half of the truth were known, it would be seen to be chiefly a matter of where *not* to use it. It may seem rank waste to let the foot-pounds of a stream do nothing but dissipate themselves in fruitless heat, degrading the universal energy and hastening the end of all things. But if, to appro-

Digitized by Google

priate those same foot-pounds for the use and convenience of man, it is necessary, first of all, to go to a place more or less remote from the other place where the foot-pounds are really wanted; secondly, to undertake costly constructive and other works around and about the stream; and, lastly, to purchase, erect, and keep in working order an alternative plant which can be conveniently called into use when the water foot-pounds fail—as they mostly do—to supply the power which is needed; if all this, and more, is necessary, there is little wonder that some engineers are content to let the foot-pounds burble their natural way along the native brook bed. Seen in this light, the problem of where to utilise water power resolves itself into a comparison between the total cost of its adoption and the total costs of other possible schemes. The balance will generally be found to turn against the water power scheme with a very decisive kick. Not that hydraulic engineering is to be blamed; it is the fault of the geological and meteorological forces which moulded these little isles and apportions their rainfall. Still, there are localities in our country where geologic steepness or meteorologic prodigality, or both combined, enables a foot-pound to be obtained cheaper than in any other way, and where this boon is a fairly constant blessing. At these hydraulic oases the exception proves the general rule.

The question which the electrical fraternity will be asking itself this week will, in all likelihood, be: Is the Powick mill site at Worcester one of these hydraulic oases, where it is worth while trying to take the energy out of the water and to transmit it along three miles of cables? Without doubt, taking the advantages with the disadvantages, the Powick mill site is far better than the average in this country. And most of the still better ones are protected in the interests of navigation, and are thus hampered or rendered useless for power purposes. Yet, although this mill site is so superior to the available average, he would be a bold man who should now say that it has been better to utilise it than to leave it alone. Time alone will reveal the precise value of the water-power at Powick; but it is even now possible to discover some of the more serious limitations to its utility. Reference is made in an article which we publish this week, describing the Worcester station, to the two conditions under which water-power at Powick becomes unavailable. The first of these, arising from drought, will occur during the summer months, at a time when the maximum demand is not very large. It is comparatively unimportant, and is only significant in so far as it shows the need for steam plant. But the second occasion for the turbines being rendered *hors de combat* is one which, if it occurs at all, is likely to take place during the wintry months, when not only is the load heavy for a longer time, but when its maximum is very much in excess of the summer maximum. What does this mean? It means that the station must be so equipped with steam plant that, without the turbines working, the maximum possible demand on the station can be adequately met. In other words, the auxiliary plant at the Powick water-power station must "coincide with and be of the same magnitude as," as it were, the water-power plant itself! To this, then, has the problem reduced itself: that water at Powick is only of use as a means of avoiding the use of already existing steam plant, at a time when to use the steam plant would be uneconomical. The turbines are a mere go-between and stand-by for the steam engines. It is a very small game for such a big candle. Nevertheless, we wish every success may attend the Worcester scheme; nothing would please us better than that it should succeed. It is a heroic experiment to make in a country like ours; and, even on that account alone, the gods should prosper it.

THE BOARD OF TRADE ELECTRICAL STANDARDISING LABORATORY.

This laboratory was established in consequence of a deputation comprising most of the prominent members of the electrical profession, to the Board of Trade in 1889, for the purpose of urging the necessity of the establishment of such an institution. A scheme was submitted by this deputation for the establishment and working of a standardising laboratory, and this scheme has been kept in view as far as was consistent with the amount of money procurable from the Treasury.

The laboratory exists for three purposes: First, to obtain and preserve standards for the measurement of electrical quantities; second, for giving the standard measurements of those quantities; and, third, to enable the Electrical Adviser of the Board of Trade to make such tests of instruments and material as may be necessary in the performance of his duties. No scientific work outside these purposes can be undertaken.

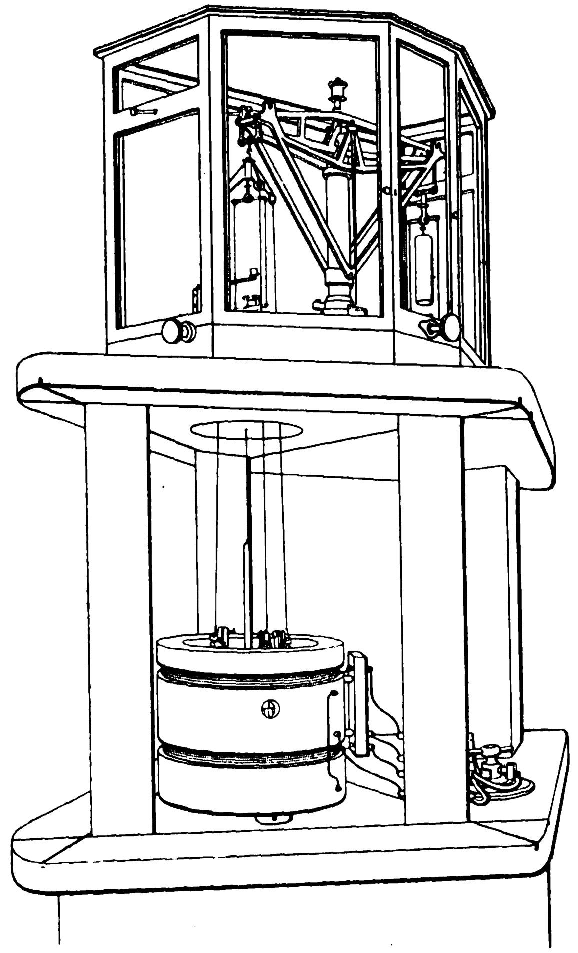

Fig. 1.—The Ampere Balance, showing the weight raised from the scale pan by the lifting gear.

Six rooms are in occupation in the basement of No. 8, Richmond-terrace, Whitehall. One of these is occupied by the gas engine and dynamos, used solely for charging accumulators; another by the accumulators, from which all the power used in making electrical measurements is obtained. These two rooms are outside the main building. The rooms within the main building are, first, the room containing the standards for current and pressure and the necessary adjuncts; second, the room containing the transforming machinery, where the power derived from the accumulators is transformed as required; third, the room occupied by the standards of resistance and the Clark cells used as sub-standards, this room being used exclusively for measurements connected with resistance and the comparison of electromotive forces; and, fourth, the verification room, where commercial instruments sent for the purpose are verified. Beyond the verification room is fitted a small chemical laboratory.

Digitized by Google

The use of these rooms will be better understood, if we begin first by describing the important instruments which they contain, and the method of working with them. As in an observatory, the laboratory has been adapted to the instruments rather than the instruments to the laboratory, and it is better, therefore, to turn attention first to the two main pieces of apparatus, the Ampere Balance, and the Volt Standard.

STANDARD OF ELECTRICAL CURRENT.

Construction and Use of the Instrument for Determining the Standard of Electrical Current.

The complete instrument is shown in perspective in Fig. 1, and the details and connections in Figs. 2 and 3. It is constructed as follows :—

Balance and Supports.—A sensitive balance, suitable for the accurate determination of weights up to five kilogrammes, with a beam 16in. in length between the knife edges from which the scale pans are hung, is fixed on an upper horizontal platform of marble, supported on four marble columns at a height of 2ft. 3in. above a similar platform fixed on a suitable stone pier, bedded solidly in a mass of concrete, and kept clear from contact with the wooden floor of the laboratory.

Marble Cylinder.—On the lower platform is placed on three supports, details of which are given below, a cylinder of white statuary marble, partly hollow (*see* Fig. 2).

The cylinder is thoroughly impregnated with paraffin wax. A block of ebonite, *e* (Fig. 2), is fixed on one side of the cylinder, and serves as a terminal board.

Fixed Coils.—Two circular grooves are cut completely round the cylinder, in which are wound coils of No. 18 standard wire gauge (0·12cm. diameter), insulated with two coverings of white silk. The wire was passed through a bath of shellac and alcohol as it was wound on the marble, and each layer was well coated with the same material when in its place.

Each coil has 16 turns per layer and 16 layers of wire.

The coils are both wound in the same direction, and the outer ends are strained tight and secured to terminals *t t* (Fig. 2).

The inner ends are passed through the marble and secured to bolts in connection with terminals *i i* (Fig. 2).

Sighting Holes.—Between the grooves on the marble cylinder, at points equidistant from each other, are bored through the marble three sighting holes, one of which is shown at *h* (Fig. 2). These holes are closed on the inside by glass, the exact centres being indicated by the intersection of two straight lines engraved in the glass, and also by the angle of a quadrant of tinfoil affixed to the glass.

Suspended Coil, Suspending Wires, &c.—A circular coil, shown in sectional elevation at *c* (Fig. 2), and of the dimensions given, is suspended from one end of the beam of the balance by means of three gilded phosphor bronze wires 0·086cm. diameter, *w w w* (Fig. 2). These wires pass through an an aperture in the upper marble platform.

The wire in this coil is the same as in the fixed coils, and is similarly insulated and varnished. There are 18 turns of wire in each layer and 18 layers. Each complete layer was allowed 24 hours to dry after being coated with shellac varnish before the next layer was put on.

The coil is covered with a taping of silk ribbon, closely laid on to overlap, and varnished with shellac in alcohol, four coats, each being allowed to thoroughly dry before applying the next one.

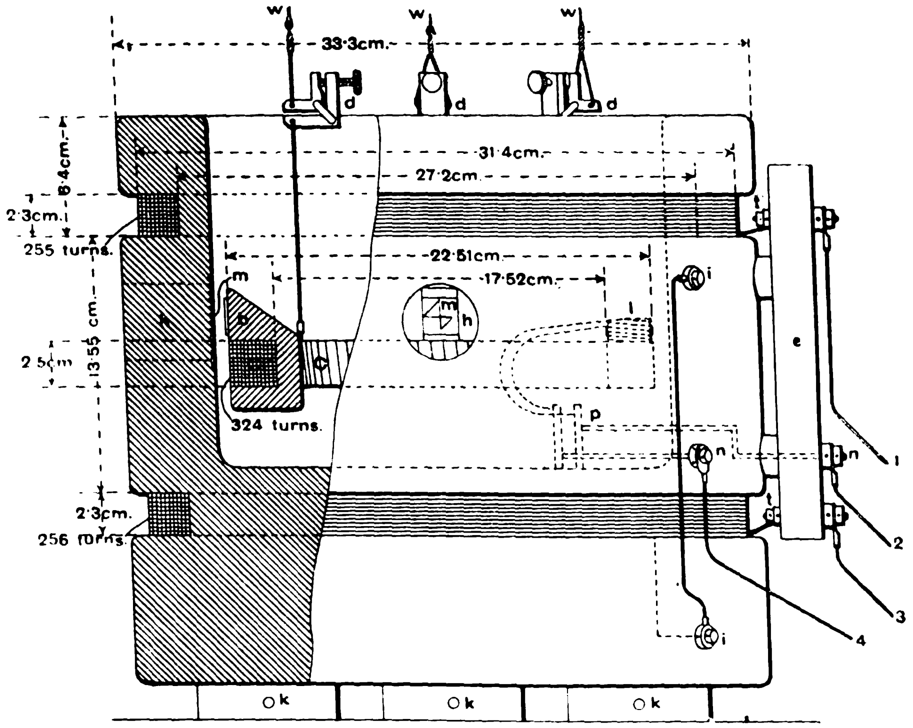

Fig. 2.—Elevation and Part Section of Marble Cylinder.

The ends of the coil are brought out near each other on the upper surface at *l* (Fig. 2). A considerable length of wire is left for each end, and is formed into a spiral, and then projected horizontally to the centre of the coil, where the stiff wires terminate, and flexible connections are made by three silk-covered silver wires, No. 40 S.W.G., from each to the posts *p* (Fig. 2), which are connected to terminals *n n*.

Three ebonite blocks *b* (Fig. 2) are fitted over the coil, as shown, and secured by a lashing of silk thread, the suspending wires being attached to brass eyelets screwed into the ebonite.

At *d d d* (Fig. 2) are shown ivory cranks for effecting the vertical adjustment of the suspended coil.

The attachment of the suspending wires to the balance is effected by ivory rings, which are hooked on to a three-legged fitting, this being hooked to the stirrup, hung on the knife edge of the beam (*see* Fig. 1).

The scale pan is also hung from this stirrup, as shown in Fig. 1.

On the upper part of each ebonite piece, *b*, facing the sighting hole *h*, is fixed a mirror, M, the centre being fixed by the intersection of cross lines and by the angle of a quadrant of tinfoil.

Adjustments.—The proper adjustment of position of the suspended coil is indicated by the coincidence of the angles of the

Digitized by Google

tinfoil quadrants on the mirrors *m*, and the glass back of holes *h*, when the eye is so held that no reflected image can be observed.

Eccentric Movement for Horizontal Adjustment.—A means of fine horizontal adjustment is provided in the supports of the marble cylinder, which are three short slate cylinders, *k k k* (Fig. 2), having projections from their upper and lower surfaces, the upper projection being eccentric and fitting in a hole in the bottom of the marble cylinder, and the lower projection being concentric and fitting in a radial groove in the marble slab.

The Weight.—The iridio-platinum weight shown in Fig. 1 can be lowered into the scale pan, and released from the outside of the case by a system of levers.

The weight is accurately 33·55 grammes.

Enclosure.—The marble cylinder is enclosed by means of three sheets of plate glass, which slide in grooves cut in the marble platforms, and when in position are in contact with the sides of the three marble columns adjacent to the cylinder, these sides being coated with baize, the plan of this enclosure being an equilateral triangle with the axis of the marble cylinder at its centre. The planes of the three glass sheets are respectively parallel with those of the glass at the back of the sighting hole viewed through them.

The balance is enclosed within a case of mahogany and glass (*see* Fig. 1), and arrangements are made as indicated for manipulating the rider weights of the balance and the ampere weight from the outside of this case.

The whole enclosure is fairly dust-tight, and sufficiently air tight to prevent any disturbance of the weighing operations by currents of air.

Connections.—The connections to the reversing switch Z (Fig. 3) are brought outside the enclosure by means of rods passing through the marble column adjacent to the ebonite block. Fig. 3 shows these connections, and the direction of the current through the various parts of the apparatus, the lower arrows over the fixed coils showing the alteration of direction caused by operating the switch.

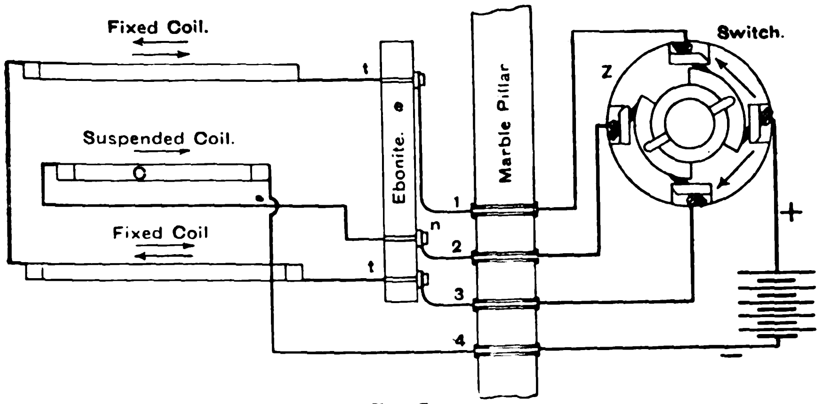

Fig. 3.

Auxiliary Current Balance.

In the construction of the standard ampere balance the chief object aimed at has been the securing of the greatest possible constancy and precision of determination.

On account of the slow period of vibration of the beam, however, the use of an auxiliary instrument has been found advantageous.

This is a special form of Lord Kelvin's current balance instrument arranged to balance with a current of one ampere passing through the coils when a certain weight is applied to one end of the beam, equilibrium being also maintained when, with no current passing, this same weight is applied to the other end of the beam.

Use of the Instrument.

The standard balance, auxiliary balance, and the instruments to be standardised, are connected in circuit with a sufficient number of accumulators, and an adjustable resistance, part of which is capable of continuous variation. The whole circuit is arranged so that a current of approximately one ampere will pass on completion of the circuit.

This current is allowed to pass continuously for at least one hour, being directed through the coils of the standard, so as to increase the force of gravity on the suspended coil, and the counterweight in the right hand pan being adjusted from time to time.

At the end of this preliminary period the current is stopped for a short time to take a reading of the zero of the auxiliary balance, and apply a correction by means of the rider weight, if necessary. The current is then again put on, and as rapidly as possible regulated by means of the adjustable resistance to exactly the value of one ampere, as indicated by the auxiliary balance.

The counterweight in the right hand pan, standard balance is also exactly adjusted.

The switch Z (Fig. 3) is then operated to reverse the current in the fixed coils, and at the same time the weight is lowered into the left-hand scale pan.

The balance should then still be maintained when the current, after adjustment, if requisite, is exactly one ampere by the auxiliary balance.

(To be continued.)

THE CONSTRUCTION OF RESISTANCES.*

BY D. K. MORRIS

(Concluded from page 629.)

Rheostats and Resistances for the Absorption of Power.

These can be divided into—those capable of perfectly gradual adjustment and step by step resistances.

The only way of having a perfectly gradual adjustment if the resistance material is in the form of wires, is to have a sliding or rolling contact. But the uncertainty of such contacts is a serious drawback to this form of resistance, especially when working with small currents; for a contact which would offer no appreciable resistance to the passage of two or three amperes might, nevertheless, measure a considerable fraction of an ohm on a Wheatstone's bridge.

The most common form of such resistance has two rollers, and the wire is rolled from one on to the other. One of the rollers is either made of slate, or is covered with an insulating material such as ebonite, asbestos, or varnished paper, while the other surface is usually nickel-plated, so as to present always an unoxidised surface.

The wire passes from one to the other over a kind of saddle, which travels along by a screw thread on the axis of the handle.

In the best forms there is, just behind the handle, a toothed wheel which gears into two identical toothed wheels at the end of each cylinder, and the tension of the wire is preserved by having a partially wound-up clock spring within one of the cylinders.

In the resistances for use with the Thomson-Houston traction motors, a rheostat cable is employed, consisting of 42 No. 20 steel wires twisted round a hemp centre.

Carbon Plate Rheostats.—This is a very useful form of resistance. The following is a description of one made by R. W. Paul, of Hatton-garden:—

Forty plates of ordinary gas carbon, $3\frac{1}{2}$in. square and $\frac{3}{8}$in. thick, are supported in, but insulated from, a metal frame, and by means of a cast-iron terminal plate and a screw these may be pressed together to any desired amount. Such a resistance carries, when compressed, 25 or more amperes without heating, and can be varied within fairly wide limits, which the makers state to be 25 ohms down to $\frac{1}{25}$th of an ohm.

Still lower resistances can be obtained by the use of an intermediate terminal plate.

Another handy form of carbon resistance is made by this firm; it is known as the Varley Carbon Rheostat, and consists of discs of flexible carbonised cloth strung on to an insulating

* A Paper read at a Student's Meeting of the Institution of Electrical Engineers, March 16, 1894.

Digitized by Google

central rod between terminal plates; and, by a nut and screw, this column can be compressed.

Liquid Resistances.—A very simple form can be made by cutting two channels side by side in a wooden base, into which are screwed two terminals, one at the end of each channel; these can then be filled with mercury. Tinned copper lugs connect the mercury with the terminals. The resistance between the latter can then be continuously varied by sliding along a copper bridge piece, the ends of which are tinned. This may be rendered more portable by replacing the two channels by vertical glass tubes filled with mercury, connected at the bottom to two terminals, and bridged over at the top by a bent copper rod, the arms of which are capable of reaching right down the tubes. In the latter form the mercury can be replaced by a solution of zinc sulphate, or other conducting liquid.

The following is a method of absorbing a large quantity of power readily. Two large lead plates are fastened to a frame so that they can be raised out of, or lowered into an insulated tub containing water. The resistance thus obtained can be varied within wide limits, not only by raising or lowering the plates, but by adding more or less acid to the water.

Taking a common value for e (0·00025), and a permissible rise of temperature of 60°C., we get *watts which can be absorbed per metre* $= 20\,d$ *in centimetres*, or $50 \times$ *diameter in inches.*

You will notice that it does not depend on the material. This is as it should be. Of course the current required to produce a waste of 1 watt per metre is not independent of the material (it is easy to show that it is inversely proportional to the square root of the specific resistance); so it will require $3\frac{1}{2}$ times as much *current* to heat a copper wire to a given temperature as a similar iron wire; but, owing to the difference of resistance, the expenditure of energy will be the same. Hence, roughly speaking, a

No. 25 wire	will absorb	1	watt	per metre.
„ 19	„	„	2	„	„
„ 16	„	„	3	„	„
„ 14	„	„	4	„	„
„ 12	„	„	5	„	„

These results must not be regarded as being worth very much, as they are very considerably altered by the state of the surface, and by the amount of air convection; but, under ordinary circumstances, they give a rough idea of the energy which can conveniently be absorbed by wires of various gauges.

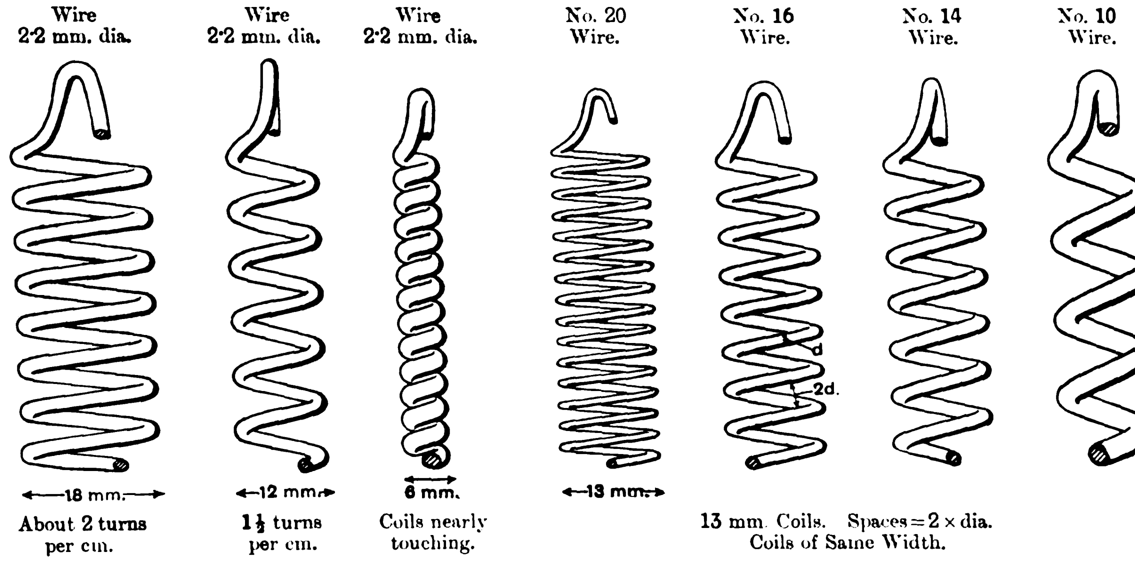

FIG. 14.—Resistance Coils. Spacing of Convolutions for most Rapid Cooling, absorbing maximum watts per metre of Wire (if same rise of temperature be allowed in all cases). From experiments by Herr Dettmar (see *Elektrotechnische Zeitschrift*, December 15th, 1893).

Step by Step Resistances.—These fall into two groups—series resistances and parallel resistances. Before proceeding to describe such resistances, some general considerations on the heating of wires in air will, perhaps, not be out of place.

To find a law connecting the diameter, d, of a conductor with that strength of current c which will raise its temperature $t$deg. above the surrounding air.

If there is equilibrium of temperature the wire must radiate heat as fast as it is generated, and this applies to any given portion of the wire; so the heat generated per second in 1cm. length of wire must be equal to that radiated and conducted away per second from the same piece. If e be the number of units of heat radiated and conducted from 1 sq. cm. of surface of the wire per second when the excess of temperature is 1°C., then $e\,t^{\circ}$ will be that, when this excess of temperature is t°C., and since the surface of 1cm. length of the wire is πd, we have—

$$\text{Heat radiated per second is } \pi\, d\, t^{\circ} e, \text{ or in ergs}$$

$$\pi\, d\, t\, e \times 42{,}000{,}000.$$

This must equal $C^2 R$, also expressed in ergs.

If C is in amperes, and R in ohms, then $\frac{C}{10}$ and $R \times 10^9$ are in absolute measure—

$$\pi\, d\, t^{\circ} e \times 42{,}000{,}000 = \left(\frac{C}{10}\right)^2 \times (R \times 10^9);$$

$$\therefore \pi\, d\, t^{\circ} e \times 4{\cdot}2 = C^2 R = \text{watts absorbed per cm. length.}$$

The above figures correspond to about 1 watt per 16 sq. cms. of surface.

[Dr. Fleming finds that, with rods made of plumbago and plaster-of-paris in various proportions, it is possible, without undue heating, to get rid of 1 watt with 6 sq. cm. of surface only.]

With wires wound in spirals, as is often done, the radiation on the inside is retarded; but the steady current of air which rises up the inside counteracts this in a measure.

According to some experiments by Herr Dettmar, of Frankfort (see *Elektrotechnische Zeitschrift*, December 15, 1893), there is a particular spacing of coils of a spiral of wire in air, for which the current is a maximum, which will cause a given rise of temperature. These are experimental results, and a definite law connecting them has not been given (*see* Fig. 14).

General Remarks on Resistance.—In series resistances it is important that the switch contact is fully large enough to bridge over the space between the points, for otherwise the circuit would be broken; and a stop must be placed so that the switch contact cannot pass beyond the point of least resistance, and so break the circuit when the maximum current was flowing.

Resistances for high-tension work should be very carefully insulated and placed out of reach of accidental contact. As a typical form of series resistance, the following, as made by Nalder Bros., may be given. Two blocks of slate in cast iron settings are fixed at a distance apart by two iron rods. Open

Digitized by Google

coils of iron wire are stretched between them, 11 in front and 11 behind, and all connected in series. A twelve-point switch is connected, so that the first point gives no resistance, the next puts two coils in circuit, the third four coils, and so on.

For many purposes parallel resistances are more convenient; for instance, in making a dynamo test, it is desirable to increase the load by equal amounts, and if the energy is taken up wholly on such a parallel resistance, the load increases with uniform steps with the number of wires which are thrown into parallel—quite unlike a series resistance. Each element of a parallel resistance must be capable of standing the full pressure for which the resistance is intended.

As an example of a good form of such resistance, I have taken one of those designed by Dr. Fleming, which we have in the dynamo room at University College (Fig. 15). Each element of the resistance consists of a pair of No. 32 manganese steel wires connected at one end to a common brass bar, passing up the wall over a porcelain insulator 12ft. above, and down again to another small insulator, whence it is finally connected to one point of a suitable parallel switch. Such an element takes a current of 2 amperes at 100 volts. In order to keep the wires tightly stretched in spite of the increase in length due to heating, which amounts to a full

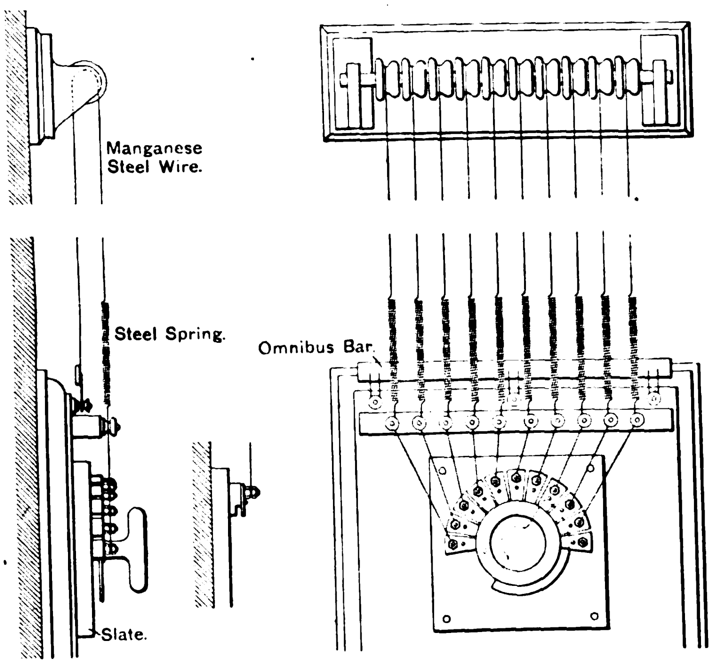

FIG. 15.—Parallel Resistance, Side and Front Elevations.

inch on this length of 24ft., a steel spring 7in. long is interposed as shown, and to avoid spoiling this spring by overheating it is shunted by a wire which carries most of the current.

Ten of these, connected with a ten-point switch, form a convenient resistance capable of absorbing nearly 3 H.P.

Wire resistances of this kind are capable of absorbing a much larger amount of power if immersed in water; but, of course, electrolysis occurs whenever a difference of potential of two or three volts is maintained in the same vessel of water. This can be obviated by using a liquid which is not an electrolyte, such as paraffin oil. The author has not had any experience of such resistances.

Incandescent lamps are extremely useful and convenient for absorbing power, especially in alternate-current work. One horse-power can be absorbed in 10 ordinary 16-c.p. lamps in a very small space compared with a wire resistance. Two groups (arranged in parallel) of 24 lamps in series will serve as load for the testing of a 5-H.P. 2,400-volt transformer. Such a resistance has *very* small inductance.

For many purposes, however, it is necessary to know the value of a non-inductive resistance in ohms; and, if this is required accurately, carbon, or any other material with a large temperature coefficient, is useless.

A form of resistance which has extremely low inductance and a large cooling surface, so as to avoid rise of temperature as much as possible, was described by Prof. Ayrton and Mr. Mather in a Paper read before the Physical Society in 1891. It is, I believe, still in use at the Central Institution.

Twelve platinoid strips, each 6m. long, 4cm. wide, and ¼mm. thick, were used. Each strip was doubled on itself, and kept separate by two layers of shellaced silk. This was bound together at intervals by a silk ribbon, and they were then arranged in a suitable frame.

WORCESTER ELECTRIC SUPPLY STATION.

Unless the unexpected happens, the forthcoming week will witness in one event the inauguration of the electric light for street and general purposes at Worcester, and the starting of the largest and most important water-power electric supply station in the United Kingdom. For many years the Worcester Corporation had been considering the advisability of acquiring control of the city lighting, and had contemplated the purchase of the gasworks. Early last year, however, these plans were modified by a suggestion that the Corporation might start an electric supply; and the utilisation of water power for the purpose was discussed. Whatever intention there may have been, at one time, to use the water of the Severn, it was quashed by the objections of the Severn Navigation Commissioners; and the timely offer of a mill-site at Powick, on the river Teme, a tributary to the Severn, at a point between two and three miles from Worcester, led definitely to the adoption of the scheme which has now almost reached practical completion. The then city surveyor and Mr. Thomas Caink, the present engineer and surveyor to the city, prepared plans involving the outlay of £23,500 on plant and apparatus, and £15,000 on the station buildings. Careful comparisons between the flow and fall of the stream at the mill site, and the probable demand for electric supply, for each month in the year, showed that it would be necessary largely to supplement the water power by steam power. The mill site at Powick suffers from two principal defects: firstly, in the drought, from an insufficient supply of water; secondly, in flood, from the partial or complete loss of head due to the tailing-up of the bottom water. As the chief causes of flood arise on the Severn, during the periods of heavy rains the entire mill site is converted into almost level backwater of the Severn, and the use of water motors is rendered impossible. The normal fall is 10ft., and the maximum possible—when the stream bed has been fully excavated—will not be more that 16ft. The turbines are worked on falls down to as low as 3ft., beyond which it is more economical to close the gate and use steam power. The normal power developed by the turbines is 350 H.P., but with exceptionally favourable conditions 500 H.P. may be utilised. No artificial mill-pond has been excavated, and the head race is far from capacious; so that the reservoir space entirely depends on the amplitude of the weir over the natural stream, and this, it need scarcely be observed, does not permit of very much storage, except during dry seasons. Consequently, the water cannot, as a rule, be conserved for use during the nightly period of maximum demand; but it serves the very useful purpose of taking the light day loads, enabling the steam plant to be shut down.

The supply station at Powick is built on arches over the mill stream, as will be seen by reference to the accompanying illustrations. We may call the attention of our readers to the expensive character of the foundation and structural work on a water-power station, as compared with an ordinary steam station. Fig. 1 shows the plan of the mill site, buildings, and generating plant. Water from the upper stream flows, by a deviation from the natural course just above the weir—which is not shown—along the head race H. A portion of this water may pass along the by-wash W to a neighbouring mill, M, or to waste; the remainder is strained by the gridiron gratings G, and passes through three passages into the wheel pits, or flumes, in which the turbines are set. These flumes are immediately below the engine house E, and are vertically above

Digitized by Google

the three arches—shown in Fig. 2—from which the water motors discharge into the tail race T. Fig. 2 gives a transverse elevation of the turbines and their setting, looking down the stream. There are four turbines, each of the mixed flow type known as the "Victor" turbine. They are supported on stone rings built into the crowns of the brick arches. The four turbines, A, B, C, D, (Fig. 2) are geared to the three alternators, 2, 3, 4, (Fig. 1) in the following manner. Turbine A is a 54in. engine, capable of developing 160 H.P., and it drives a vertical shaft, upon the upper end of which is carried a large morticed wheel, the teeth of which are of Scotch fir. This horizontal wheel is geared to a vertical cast-iron bevel wheel on a countershaft which is in alignment with the spindle of a cast-iron rope pulley. On the other side of this pulley, and also in alignment with its spindle, is the extended crank shaft of a vertical steam-engine. The 100 H.P., and turbine D is a 30in. engine, capable of developing about 60 H.P. These two turbines will together develop about the same power as either A or B. The object in view in thus subdividing the engine power of one set is to enable a small amount of load to be met without working a turbine at less than full power. A turbine worked at very much below its normal load is far less efficient than at full load. The arrangement of the turbines with respect to the gearing and alternators is shown in the longitudinal section of the mill site and plant in Fig. 3. This illustration also shows the excavation and construction work which has been rendered necessary in developing the site, the natural bed of the stream being shown at the extreme right of the drawing.

The chief feature of interest in the Worcester electric supply station being the use of water power, we have written our descriptive account of this station almost entirely from this point of

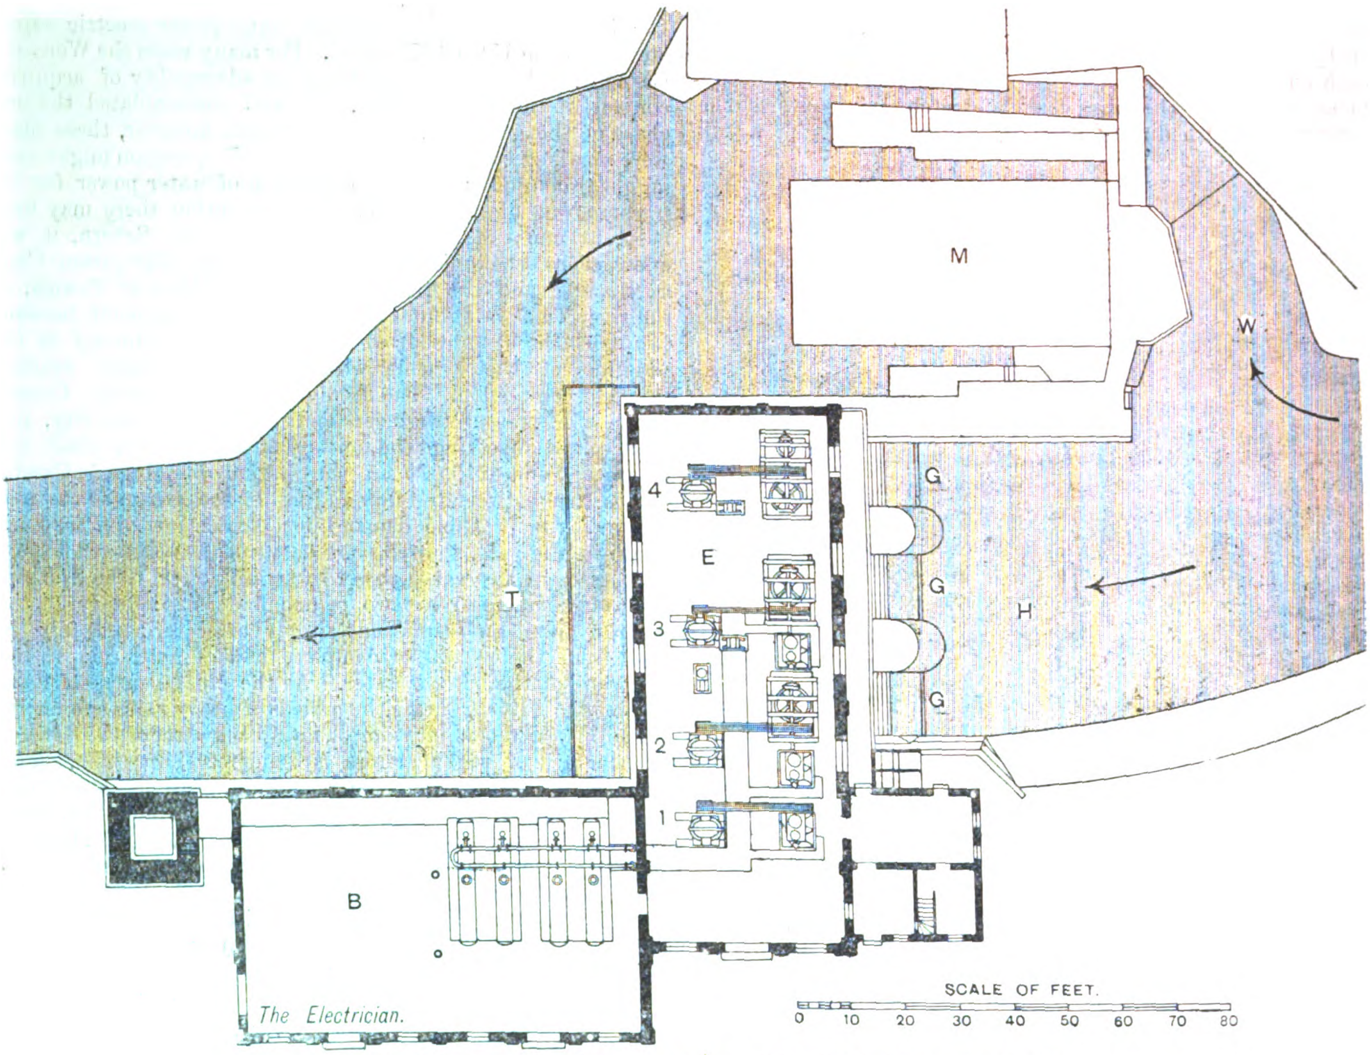

FIG. 1.—Worcester Electric Supply Station. Plan of Mill Site and Machinery.

pulley drives the 125-kilowatt alternator 2, by means of 10 ropes. By means of a four-jaw claw clutch, the turbine countershaft can be coupled to the pulley spindle; or, by means of a Snyers flexible coupling, the steam-engine can be coupled to it. When both couplings are fast, both steam and water-power may be used for driving the same alternator. Each of the alternators is constructed to develop 58 amperes at a pressure of 2,200 volts, with a frequency of alternation of 100 ∿ per second. Turbine B is geared to the alternator 3, and to a similar steam-engine, in the same manner as turbine A, the two sets being exactly similar in every respect. The end sets of plant, 1 and 4, however, are somewhat different. The alternator 1 is capable of being driven only by steam power; the alternator 4 is capable of being driven only by water power; namely, by the two smaller turbines, C and D. Turbine C is a 48in. engine, capable of developing a little over view. The electrical features of the system present nothing of novelty or special interest, with the exception of the system of mains which has been adopted, and reference to which will presently be made. Some further particulars of the utilisation of water power at Powick may, therefore, be interesting and instructive. We have said that a mixed flow type of turbine is in use. An illustration of the vanes in this turbine is shown in Fig. 4. The water passes from the wheel pit, through a number of guide blades, into the upper spaces between the vanes. Its course in then inwards, then downwards, and, finally, obliquely outwards, as it glides over the vane surfaces. After leaving the turbine the water enters the draught tube, the lower lip or orifice of which is immersed in the tail water. This tube is shown in both Figs. 2 and 3, and its object is to enable the engine to utilise the head down to the bottom level, however low or high the water may stand in

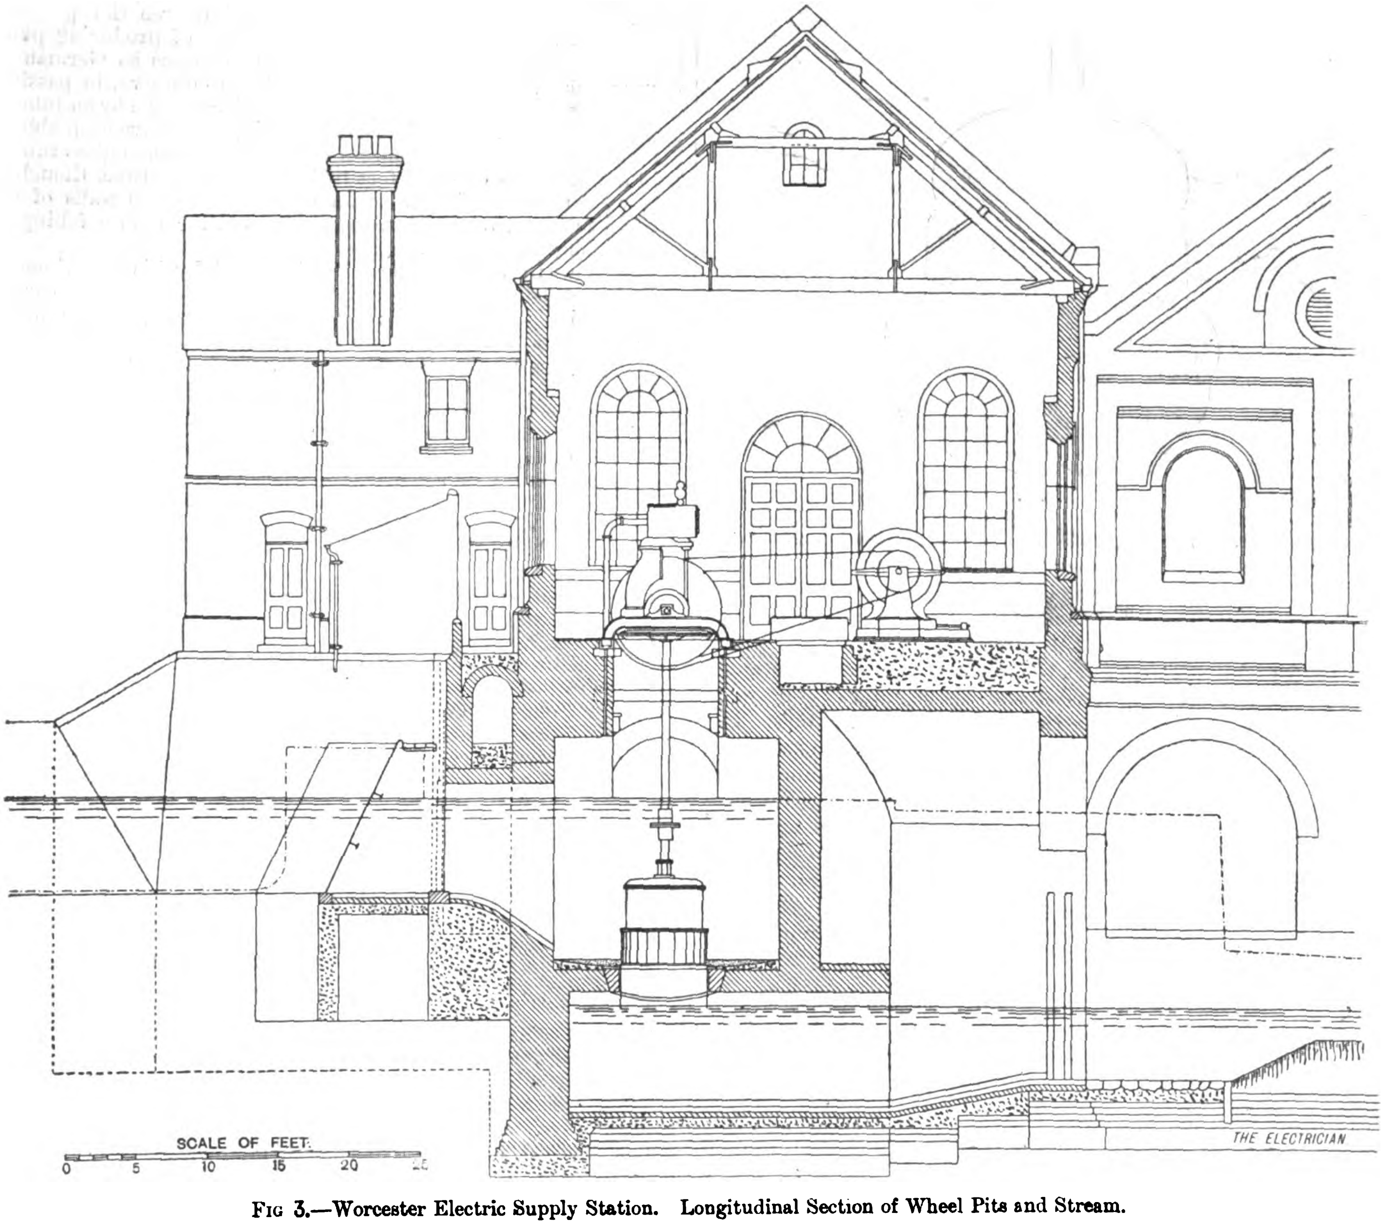

Fig 3.—Worcester Electric Supply Station. Longitudinal Section of Wheel Pits and Stream.

Digitized by Google

the tail race. The guide blades of the turbine form an outer and fixed circle round the rotating vanes. By varying the orifice given by these blades, the flow of water through the engine, and the power developed by it, may be regulated. At Powick this regulation is effected by means of a cylinder gate or shutter, which envelops the guide blades. By adjusting the vertical position of this cylinder the flow of water between the guides may be varied from a maximum, when the gate is fully lifted, to zero, when the gate is quite shut down. This requires that the entire gate shall be moved over a range equal to the height of the guide passages; and to effect this purpose a supplementary governor, worked by the energy of the turbine, is used. The governor gear consists of an ordinary pendulum governor, the duty of which is to throw into action a pawl and ratchet wheel whenever any serious departure from the normal speed occurs. The ratchet gear is actuated by the turbine; and, whenever it is thrown into action, it will commence to feed the ratchet train onward or backward until the proper "gate" has been adjusted. That this form of governor is essentially lacking in promptness is one of the most serious drawbacks to its use where electric lighting is being done. But the problem of regulating water motors for electric lighting is by no means an easy one, and it will be instructive to observe with what measure of success it has been dealt with at Powick.

The great distance between the area of supply at Worcester and the generating station necessitated, of course, the employment of the high-pressure system; and a pressure of 2,000

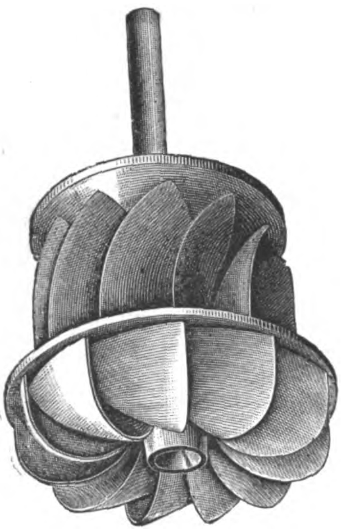

FIG. 4.

volts at the transformers, or 2,200 at the generator terminals, was decided upon. To minimise the loss of power by leakage, it was considered desirable to adopt the system of oil insulation known as the "Brooks" system. Our readers will find some account of this system in *The Electrician*, Vol. XXIV., p. 87. The head of oil necessary for the Worcester mains is obtained by means of an oil tower, situate about midway between Worcester and Powick on the rising ground of St. John's. The average head is about 30ft. of oil; but we understand that in some parts of the system a head of about 50ft. is attained. At a point but a few yards beyond the bridge over the Severn, by which the mains are led into the city, there is a large and well-appointed transformer pit, which is well lighted and faced with enamelled brick. This pit or cellar also serves the purpose of an arc switch room, the switches controlling the two street arc lamp circuits being placed here. Each of these circuits contains 13 small transformers, located in the lamp standards, each transformer supplying one street arc lamp.

In addition to supplying power for lighting purposes, the generating machinery at Powick is utilised for working the pumps at the waterworks. Two sets of electrically-driven pumps have already been provided, and it is probable that if this feature of the system should prove successful the Corporation will find further use for their electric power in sewage pumping and other mechanical work. Such duties as these, regular and steady as they will probably be, must prove very beneficial to the economy and successful working of the generating plant. For ordinary customers the power will be supplied at 5d. per unit, with discounts for cash and on all accounts exceeding £25 per annum. We understand that by the time the station is started there will have been some 3,850 lamps of 8 c.p. wired in the consumers' houses.

Our thanks are especially due to Mr. W. H. Preece, the consulting electrical engineer to the Worcester Corporation, and to Mr. Thomas Caink, the city engineer, for permission to reproduce some of the illustrations which accompany this article, and for the information which they have so readily and kindly supplied; they are also due to Mr. Leonard Wigan, the Clerk of the Works, for his kindness in accompanying us over the works.

ON THE VELOCITY OF CATHODE RAYS.*

BY J. J. THOMSON, M.A., F.R.S.

The phosphorescence shown by the glass of a discharge tube in the neighbourhood of the cathode has been ascribed by Crookes to the impact against the sides of the tube of charged molecules driven off from the negative electrode. The remarkably interesting experiments of Hertz and Lenard show that thin films of metal when interposed between the cathode and the walls of the discharge tube do not entirely stop the phosphorescence. This has led some physicists to doubt whether Crookes's explanation is the true one, and to support the view that the phosphorescence is due to ætherial waves of a very small wave length, these waves being so strongly absorbed by all substances that it is only when the film of the substance is extremely thin that any perceptible phosphorescence occurs behind it. Thus on this view the phosphorescence is due to the action of a kind of ultra-violet light, which possesses in an exaggerated degree the property possessed by the ultra-violet rays of the sun of producing phosphorescence when incident upon such substances as German or uranium glass. It is, perhaps, worth while to observe, in passing, that the light produced in an ordinary discharge-tube by an intense discharge is very rich in phosphorogenic rays. I have been able to detect phosphorescence in pieces of ordinary German-glass tubing held at a distance of some feet from the discharge tube, though in this case the light had to pass through the glass walls of the vacuum-tube and a considerable thickness of air before falling on the phosphorescent body.

The view, to which Lenard has been led by his experiments, that the cathode rays are ætherial waves demands the most careful consideration and attention; for if it is admitted, it follows that the æther must have a structure either in time or space. For these cathode rays are deflected by a magnet, which, so far as our knowledge extends, does not produce any effect on ultra-violet light unless this is passing through a refracting substance: thus, if the cathode rays are supposed to be ultra-violet light of excessively small wave-length, it follows that in the æther in a magnetic field there must either be some length with which the wave-length of the cathode rays is comparable, or else some time comparable with the period of vibration of these rays.

It might be objected that it is possible that the action of a magnet on the cathode rays is a secondary effect, and that the primary action of the magnet is to affect the main current of the discharge passing between the positive and negative electrodes, and thus to alter the distribution of the discharge entering the cathode; this would affect the distribution of the places of greatest intensity over the cathode, and thus indirectly the distribution of the waves emerging from it. To test this point I shielded the cathode from magnetic forces by means of a magnetic screen consisting of a ring made of soft iron wire; the length was about 1·5in., its thickness was about 0·75in. When this ring encircled the cathode a magnet was brought up to the tube; the phosphorescent patches inside the ring were not now affected by the magnet, but those on the parts of the tube farther away from the cathode and outside the iron ring were very much displaced by the magnet; thus proving that the magnet acts on the cathode rays through the whole of their course, and does not merely affect the place on the cathode at which they have their origin. There thus seems no escape from the conclusion that the establishment of the hypothesis that the cathode rays are ætherial rays would also prove the finiteness of the structure of the æther.

The following experiments were made with the view of determining the velocity with which the cathode rays travel, as it seemed that a knowledge of this velocity would enable us to discriminate between the two views held as to the nature of the cathode rays. If we take the view that the cathode rays are ætherial waves, we should expect them to travel with a velocity comparable with that of light; while if the rays consist of molecular streams, the velocity of these rays will be the velocity of the

* From the *Philosophical Magazine*.

Digitized by Google

molecules, which we should expect to be very much smaller than that of light.

The method I employed is as follows:—The discharge tube was sealed on to the pump, and the two electrodes were placed at the neck of this tube. The discharge tube was covered with lampblack, with the exception of two thin strips in the same straight line from which the lampblack was scratched: these strips were about 10cm. apart; the one nearest to the negative electrode was about 15cm. from the electrode, the other was 25cm. from the electrode. They were chosen so as to phosphoresce with, as nearly as could be judged, equal brilliancy when the discharge passed through the tube.

The light from the phosphorescent strip fell upon a rotating mirror about 75cm. from the tube. This mirror is the one used by me in my experiments on "The Velocity of Propagation of the Electric Discharge through Gases" (*Proc.* Roy. Soc., 1890), and is described in that Paper. The only change made in the mirror was to replace the single plane strip of silvered glass which was used in the previous experiments by six strips of mirror fastened symmetrically round the axis. The mirror was driven by a large Gramme machine.

The images formed by reflection from the mirror were observed through a telescope, of which the object-glass was a large portrait photographic lens of 4in. aperture, the eye-piece a short-focus lens; when the mirror was at rest the two images of the phosphorescent strips were seen in the same straight line, and the adjacent ends of the two images were brought into coincidence by inserting between one of the phosphorescent strips and the mirror a very acute-angled prism. The point of the experiment was to see if the images of the two phosphorescent strips remained in the same straight line when the mirror was in rapid rotation. If, for example, the cathode rays travelled with the velocity of sound, they would take about $\frac{1}{3300}$th of a second to pass from one strip to the next; if the mirror were rotating 300 times a second it would, in the interval taken by sound to pass from one strip to the next, rotate through about 33deg.; the displacement of the image produced by a rotation one thousandth part of this could easily be detected.

When the phosphorescence was produced by the discharge of an ordinary induction-coil, the images seen in the telescope after reflection from the revolving mirror were drawn out into very faint ribands of light without definite beginnings or ends, so that it was impossible to say whether or not there was any displacement of one image relative to the other.

I tried a considerable number of phosphorescent substances in the hope of obtaining sharp images, but without success. The substances I tried were ordinary German-glass, uranium-glass, lead-glass, the cyanide of magnesium and platinum, asaron, æsculine, and Schuchardt's "Leuchtfarbe."

The gradual fading away of the phosphorescence after the exciting cause has been removed, is one reason why one of the edges of the image formed by the revolving mirror should be indistinct; this cannot be remedied unless some substance can be found which ceases to phosphoresce immediately the incidence of the negative rays ceases. I was unable to find any substance possessing this property; of the substances I tried, uranium-glass was the one whose phosphorescence died away most quickly.

I tried several experiments with a specimen of asaron. This substance was found by Lenard to cease to phosphoresce so quickly after the cessation of the phosphorogenic rays that he could not detect its duration in his very sensitive phosphoroscope. My specimen of asaron must, I think, have been impure, as it phosphoresced a coral-pink instead of violet, as described by Lenard, and its phosphorescence showed a very appreciable duration; in addition to this, it did not give out nearly enough light to be of any use in experiments of this kind.

But even though the images of the phosphorescent strips have one edge (that corresponding to the end of the phosphorescence) indistinct, we can get the information we require about the velocity of the cathode rays if we can get the image of the edge corresponding to the beginning of the phosphorescence sharp and distinct.

After unsuccessful attempts with several methods, I found that this could be done in the following way, using the oscillatory currents produced by the discharge of a Leyden jar: The electrodes of the discharge tube were connected with the ends of the secondary coil of a transformer, whose primary circuit consisted of a coil of wire with the ends connected to the outside coatings of two Leyden jars, the inside coatings of which were connected with the extremities of an induction-coil; the secondary coil of the transformer had about 30 turns for each turn of the primary coil. It was heavily insulated, and both primary and secondary were immersed in an oil-bath. This transformer easily gave sparks 7in. or 8in. long in air, and when connected to the terminals of a discharge-tube made of uranium-glass produced a very vivid phosphorescence. When the phosphorescence was produced in this way, the images after reflection in the rotating mirror had one edge sharp and distinct, though the other edge was indeterminate in consequence of the duration of the phosphorescence.

When the images of the two bright phosphorescent strips were observed in the telescope, after reflection from the rapidly revolving mirror, their bright edges were seen to be no longer in the same straight line; if the images came in the field of view from the bottom and went out at the top, then the sharp edge of the phosphorescent strip nearest the electrode was lower than the edge of the other image; if the direction of rotation of the mirror was reversed so that the images came in at the top of the field of view and disappeared at the bottom, then the bright edge of the image of the phosphorescent strip nearest the negative electrode was higher than the bright edge of the image of the other strip. This shows that the luminosity of the strip nearest the cathode begins to be visible before that at the strip more remote; and that the retardation is sufficiently large to be detected by the revolving mirror. This retardation might be explained, (1) by supposing it due to the time taken by the cathode rays to traverse the distance between the phosphorescent patches; or (2) we might suppose that, though the cathode rays reached the two phosphorescent patches almost simultaneously, it took longer for the rays falling on the patch at the greater distance from the cathode to raise the patch to luminosity. In other words, there may be an interval between the incidence of the cathode rays and the emission of the phosphorescent light, this interval being greater the further the phosphorescent patch is from the cathode. This latter supposition cannot, however, explain the displacement of the images for the following reasons: The sharpness and brightness of the edge of the image show that the phosphorescence, when once it is visible, must attain its maximum brilliancy in a time very small compared with the time taken by the mirror to rotate through an angle large enough to produce the observed displacement of the images. Again, the two phosphorescent patches are as nearly as possible of equal brightness, so that there can be very little difference in the intensity of the cathode rays falling upon them: it was for this reason that both the phosphorescent patches were taken some distance down the tube. Again, I took a tube which was bent so that the cathode rays fell more directly upon the patch farther from the cathode than upon the other patch, so that in this case the phosphorescence of the more remote patch was brighter. The displacement of the images with this tube was just the same as for the previous, *i.e.*, the phosphorescence commenced at the patch nearest the cathode sooner than at the other patch; whereas if the displacement of the images was due to the interval between the arrival of the rays and the beginning of the phosphorescence it should have commenced at the patch furthest from the cathode, as this was the most exposed to the cathode rays and phosphoresced with the greatest brilliancy.

I conclude, therefore, that the displacement of the images is due to the time taken by the rays to travel from one patch to the other. This displacement enables us to measure the velocity of the cathode rays. The amount of displacement observed through the telescope is not constant: even though the mirror is turning at a uniform rate, there are quite appreciable and apparently irregular variations in the amount of the displacement of the images seen in the course of a few minutes. I think these are due to irregularities in the sparks discharging the jar, and the consequent irregularities in the electromotive force acting on the discharge tube.

When the mirror was rotating 300 times a second, the bright edges of the two patches were on the average separated by the same distance as the image of two lines 1·5mm. from each other placed against the discharge tube. Since the distance of the discharge tube which contained hydrogen from the mirror is 75cm., the mirror must, in the time taken by the cathode rays to pass from one patch to the other, have turned through the angle whose circular measure is $\frac{1 \cdot 5}{2 \times 750}$.

Since the mirror makes 300 revolutions per second, the time it takes to rotate through this angle is

$$\frac{1 \cdot 5}{2 \times 750 \times 2\pi \times 300} = \frac{1}{6\pi \times 10^5};$$

and since the distance between the patches is 10cm. the velocity of the cathode rays is

$$6\pi \times 10^6 \text{cm./sec.},$$

or about $1 \cdot 9 \times 10^7$cm./sec.

This velocity is small compared with that with which the main discharge from the positive to the negative electrode travels between the electrodes (*see* J. J. Thomson, *Proc.* Roy. Soc. 1890). I verified this by inserting an electrode into the far end of the tube used in the previous experiment, and observing the images formed when a bright discharge passed down from the electrode at the beginning to the electrode at the end of the tube. The light from the luminous gas shines through the places where the lampblack has been scraped from the tube, and we get two images, which when the mirror is at rest coincide in position with the images of the two phophorescent patches in the previous experiment. These

Digitized by Google

images, however, unlike the phosphorescent one, remained in the same straight line when the mirror was rotating rapidly, thus proving that the velocity of the main discharge is very large indeed compared with that of the cathode rays.

The velocity of the cathode rays is very much greater than the velocity of mean square of the molecules of gases at the temperature 0°C. Thus, for example, at 0°C. the velocity of mean square of the molecules of hydrogen is about $1{\cdot}8 \times 10^5$ centimetres per second: the velocity of the cathode rays is about one hundred times as great. The velocity of the cathode rays found from the preceding experiments agrees very nearly with the velocity which a negatively electrified atom of hydrogen would acquire under the influence of the potential fall which occurs at the cathode. For, let v be the velocity acquired by the hydrogen atom under these circumstances, m the mass of the hydrogen atom, V the fall in potential at the cathode, e the charge on the atom; then we have, by the conservation of energy,

$$m v^2 = 2 V e.$$

Now e has the same value as in electrolytic phenomena, so that $e/m = 10^4$.

Warburg's experiments show that V is about 200 volts, or 2×10^{10} in absolute measure. Substituting this value, we find

$$v^2 = 4 \times 10^{14},$$

or

$$v = 2 \times 10^7 \text{cm./sec};$$

a value almost identical with that found by experiment. The very small difference between the two is, of course, accidental, as the measurements of the displacement of the images on which the experimental value of v was founded could not be trusted to anything like 5 per cent.

The action of a magnetic force in deflecting these rays shows, assuming that the deflection is due to the action of a magnet on a moving electrified body, that the velocity of the atom must be at least of the order we have found.

Consider an atom projected parallel to the axis of the tube which is situated in a uniform field of magnetic force, the lines of magnetic force being at right angles to the axis of the tube. Let H be the intensity of the magnetic force. Then, if m is the mass of the atom, v its velocity, and ρ the radius of curvature of its path, we have

$$\frac{m v^2}{\rho} = H e v,$$

where e is the charge on the atom; since e/m for hydrogen is 10^4, we have

$$v = \rho H \times 10^4.$$

I cannot find any quantitative experiments on the deflexion of these rays by a magnet; but ordinary observation shows that it would require a strong magnetic field to make ρ as small as 10cm., which would mean clearing the tube of phosphorescence except within about 10cm. of the cathode. If v were 2×10^7, this would give H = 200, which is not extravagant.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *September* 21, 1894.

The Feeder and Main Patent.—The recent decision nullifying the Edison feeder and main patent marks the growing tendency of United States courts towards a more rational treatment of questions relating to patents. The opinion of the court below, whose decision has been reversed, dwelt much on technicalities which it was apparent from the language were little understood by the judge, and therefore liable to a wrong construction. The opinion was also remarkable for philosophical and scientific dissertations that had but a remote bearing on the facts of the case, and the admiration of the judge for the "Wizard of Menlo Park" received many fervid expressions. The recent decision, however, is strictly judicial in tone and confines itself to the subject matter of the claims and condemns the action of the lower court in introducing ulterior considerations extending the importance of the patent. The conclusion of the final court is that the feeder system had previously been used in electro-plating, was described in the Khotinsky patent of 1875, and is, besides, no invention, as the use of feeders as described involved at the date of the patent only the exercise of the common skill and knowledge of the electrician.

The American Institute of Electrical Engineers.—At the September meeting of the American Institute of Electrical Engineers, two Papers were presented, one by Dr. Bedell and Mr. Carl Kinsley, on "A Study of the Residual Charge of Condensers and their Dependence upon Temperature," and the other by Mr. E. A. Sperry on "The Electric Brake in Practice." The first-named Paper was merely read by title, and is a lengthy account of experiments as to the soaking-in effects of dielectrics. The conclusions are that the action of a condenser is dependent to such a marked degree upon its earlier history, that its previous charges may be of more importance in determining its action under certain circumstances than charges received later. It was found that the resistance of pure oils is constant at one temperature but falls off rapidly with the temperature, and that there are no absorption or residual effects to be met with in such oils. In solid dielectrics the effects of absorption are diminished as the temperature is increased. The Paper of Mr. Sperry is of a commercial character, but, although diffuse and disjointed, gives much information in regard to the subject of braking street cars. In the discussion that followed the reading of the Paper, it was pointed out that the combination of the brake ring and car wheel formed a dynamo brake, whose advantage over the car motor acting in the same capacity was that destructive wear on the gears was avoided. It should be added that the braking surfaces are kept lubricated by a graphite brush located in the gap, the inventor claiming that thereby the eddy currents are permitted to circulate more freely between the brake ring and the car wheel.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The 1894 Edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook, from October 1st, is 6s. post free; abroad 5s. 6d. *The 1895 edition is in active preparation.*

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell, with this title, will be ready in October. It will contain the latest information respecting the application of electric energy to mining purposes, in which the author has had much experience. The book is well printed, on good paper, and will contain nearly 250 illustrations, a large proportion of which have been specially made for the book. The price is 10s. 6d., post free 11s. (abroad 11s. 6d.). Orders can now be sent in.

"THE WORK OF HERTZ."—The lecture delivered by Dr. O. J. Lodge at the Royal Institution on June 1st is reprinted with corrections and additions, and many original illustrations, price 2s. 6d. net.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., will be ready early in October, handsomely bound, full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

TENDERS INVITED.—The Directors of the Lancashire and Yorkshire Railway invite tenders for the supply of the Company's ordinary requirements of various articles during the twelve months ending October 31, 1895. Full particulars and forms of tender can be obtained at the Stores Department, Osborne-street, Manchester, where samples can also be seen. Tenders have to be in by 10 a.m. on October 8th.

——— Mr. John Annan, manager for the liquidator in J. W. Hobbs and Co. (Limited), invites tenders for the supply and erection of boiler house plant, engine house plant, switchboard, instruments, &c., for the electric light and power installation at the large block of hotel buildings now erecting on the Salisbury Estate, Victoria Embankment, and Strand, London, W.C. Plans and specification, &c., can be obtained of Mr. R. Hammond, consulting engineer, Ormonde House, Great Trinity-lane, E.C., on and after October 5th; and tenders must be sent in before Friday, October 26th. Further particulars are given in our advertisement columns.

Digitized by Google

Tenders Invited.—The Edinburgh Corporation require tenders for providing and erecting the cast-iron battery standards in the Torphichen-street electric lighting central station. The plans may be obtained from the borough engineer, 1, Parliament-square, Edinburgh, to whom tenders must be sent by 10 a.m. on the 8th inst.

Tenders Accepted.—The Cheltenham Town Council have accepted the tender of Messrs. Humpidge and Co., of Stroud, for the supply of an overhead travelling crane for the electric lighting station at £82; 21 tenders were received. Twenty-two tenders were sent in for the supply of casings for street boxes, and the lowest, that of Messrs. T. Spittle and Co., at £6. 10s. per ton was accepted.

Liquidations.—A petition has been presented for the winding up of Messrs. R. C. Cutting, Douglass and Co. (Limited), and is down for hearing at the Royal Courts of Justice, London, on the 24th inst.

——— Claims against the estate of Messrs. Newington, Priddle and Co. (Limited) must be sent in to Mr. C. J. Stewart, the Official Receiver, 33, Carey-street, W.C., by the 9th inst.

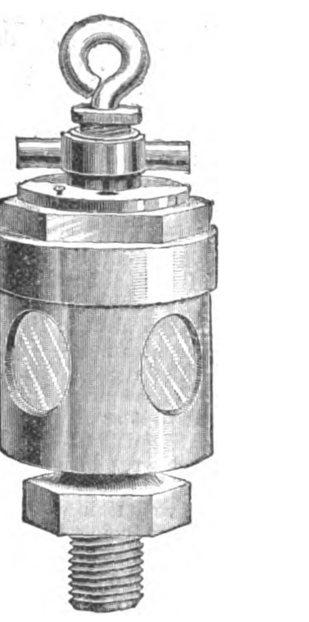
——— A meeting of the shareholders of the Halifax Mutual Electric Light and Power Company (Limited) is to be held at the Townhall Buildings, Halifax, on the 25th inst., at noon, for the purpose of receiving an account of the winding up.

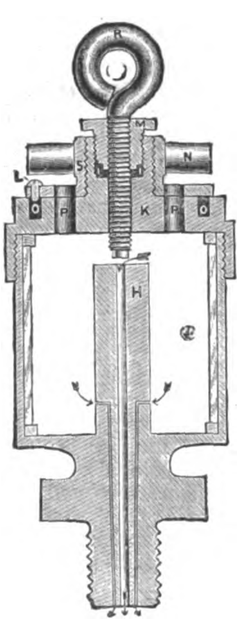
Sales by Auction.—Messrs. Wheatley Kirk, Price, and Goulty will, on Wednesday the 17th inst., at York-street Works, Lambeth, S.E., dispose of a quantity of modern engines, boilers, machine tools, and other plant and machinery, the property of Messrs. W. H. Allen and Co. The sale is necessitated owing to the removal of the firm to their new works at Bedford. The sale includes an electric lighting installation. Catalogues can now be had from the auctioneers, at 49, Queen Victoria-street, E.C., or Albert Chambers, Albert-square, Manchester.

Removal.—Messrs. Gilbert and Co. have removed from Hanway-street to more extensive works at 142a, Oxford-street, London, W. The Kensington offices remain as hitherto.

"L'Industrie Électrique."—The new address of our Paris contemporary is 12, Rue de Chantilly, Paris, to which all communications should in future be addressed.

Safety Lubricators.—Messrs. W. H. Willcox and Co., of Southwark-street, S.E., have recently placed on the market the Willcox safety automatic double-feed crank-pin lubricator, which is illustrated herewith. This is claimed to be the only lubricator





specially made for the crank pins of engines, pumps, &c. The feed can be regulated to the one-thousandth part of an inch to suit the exact speed at which the crank is running, only the absolutely required quantity of oil being supplied. This regulation is effected by giving the piston H more or less play, as circumstances require. By this means waste is avoided, as no oil can run away when the crank is at rest, the piston coming down on to its seating, and thus closing the outlet. The adjustment is simple when once the screw is set, and refilling is effected by turning the handle N to the left and pouring the oil in the holes opened on the top of the cover. By turning the handle hard to the right the cover is closed, and the lubricator is ready for use again. The body of the lubricator is of glass, and is enclosed in a strong gunmetal casing. By this means the quantity of oil in the lubricator is always on view. This is undoubtedly a strong recommendation, as the need for an effective sight-feed lubricator has long been felt. It is stated that considerable success has attended the introduction of this lubricator, as many of the largest engine builders are now adopting it. Makers of fixed engines for electric lighting plant are amongst those for whom the lubricator is specially adapted.

Fire.—Messrs. J. D. F. Andrews and Co. inform us that their works at Marsham-street, Westminster, S.W., have been completely burnt out. Temporary arrangements have been made with Messrs. Sharp and Kent, by which work will be carried on as usual. Temporary offices have been opened at 34, Victoria-street, S.W.

Aberdeen.—At a meeting of the Gas and Electric Lighting Committee of the Aberdeen Town Council held on Wednesday, 26th ult., the City Electrical Engineer (Mr. Ruthven-Murray) reported that, in consequence of the large and increasing demand for electric energy, an extension of plant would be immediately required. He stated that there were now 80 consumers, having in all 7,000 lamps connected to the mains. It will be remembered that the station was opened on February 28th last, and the fact that an extension is required in less than seven months shows with what popularity the light has been received. The progress of electric lighting in Aberdeen has been exceptionally rapid and successful. The supply was commenced at a most disadvantageous time, as the city is so far north that in summer there is practically no night. A large proportion of the load is for shop lighting; but it also includes three hotels, a few private houses, Robert Gordon's College, and the School of Art. The committee resolved that Prof. Kennedy should be requested to report as to what additional plant he would recommend to be provided.

Aberystwith.—On Tuesday last the Mayor and Corporation inaugurated the installation of the electric light at the marine front and main portion of the town by a banquet; 2,000-c.p. arcs are used for the front and the main thoroughfares. These are placed about 45 yards apart.

Antwerp Exhibition Awards.—Diplomas and medals of honour have been awarded to the following firms associated with the British exhibits at the Antwerp Exhibition: Tangyes (Limited) and Chance Brothers. Gold medals have been awarded to Dowson's Economic Gas Power Company and Messrs. Crompton and Co.; and grand prizes to Messrs. Johnson, Matthey and Co., Babcock and Wilcox (Limited) and Galloways (Limited), and awards have also been offered to Messrs. Musgrave and Co. and Messrs. Siebe, Gorman and Co. The whole of the exhibitors at the Exhibition were, on Wednesday evening last, entertained at a banquet in the Festival Hall by the members of the Executive Committee of the Exhibition.

Bacup.—The first business premises in the Rossendale district lighted are those of Messrs. Holden and Co., tea and coffee merchants, Union-street, Bacup. The generating plant is on the premises.

Bristol.—The Electrical Committee of the Corporation, at their last meeting estimated that £3,250 would be required for their purposes from the next general district rate, which is £1,500 less than the demand made last year. There is a hitch in the proposal to extend the mains to Redcliffe so that St. Mary's Church could have the electric light, and the Committee have determined to ascertain definitely whether the church authorities propose to proceed with the scheme, as otherwise the amount proposed to be spent on the extension can be otherwise utilised. Applications for current have been received from Highbury Chapel and Old King-street Baptist Chapel, but the Committee will not be able to accede to the requests unless a sufficient number of other consumers can be found on the route. The laying of the Clifton extension will shortly be commenced, and, it is hoped, will be completed by the end of the month, so that the current can be supplied by November 1st.

Cardiff.—The local authorities have issued an explanatory pamphlet of their electric lighting undertaking. It is announced that the supply of current will be ready in a week or two.

Chatsworth.—The electric lighting work at this beautiful residence of the Duke of Devonshire is now practically complete. About 1,000 incandescents are used, and the fittings include a magnificent chandelier for 48 lights in the drawing room. A duplicate service is provided.

Cheltenham.—On Wednesday Mrs. Wethered, the Mayoress, laid the memorial stone of the new electric lighting station at the refuse destructor near the Midland railway station.——The gas company have announced the reduction of 2d. per 1,000 in the price of gas. The inhabitants are now only awaiting an increase in the illuminating power of that product, when they will rest satisfied until the electric lighting installation is complete.——The Town Council have instructed their electrical engineer to procure the testing apparatus required at the central station, at a cost of about £300. Out of the sum of £16,000 to be borrowed for electric lighting purposes, £5,000 was borrowed at $3\frac{1}{2}$ per cent. from Messrs. D. Migley and Sons, of Manchester.

Digitized by Google

THE COMMERCIAL CABLES.—The Commercial Cable Company announce that the cable landing at Pier A, North River, New York City, is completed, and is in perfect working order. The Company now have three complete submarine telegraph lines between the United States and Europe, which are connected with the landlines of the Postal Telegraph Company and the Canadian Pacific Telegraphs.

DERRY.—A request from the Port and Harbour Commissioners, requesting that a supply of electric current be provided for the cattle pens to enable veterinary inspection to be performed at night, has been referred by the Town Council to the solicitor. At the last meeting of the Electric Lighting Committee, Mr. Christie presented his report, and referred to the breakages in the electric light cables. Mr. Councillor Thompson brought serious allegations against the Council's electrical engineer, which the Mayor said it would be necessary for Mr. Blake to be present to answer. A special meeting was subsequently held to discuss this, the latest phase of the vexed question of the electric cables at Derry.

EDINBURGH.—On Tuesday the Town Council remitted to the Lighting Committee to consider and report on the proposed lighting by electricity a number of the leading thoroughfares of the town.

ELECTRIC TRAMWAY IN DUBLIN.—It is understood that the work in connection with the construction of the electric tramway between Kingstown and Dalkey will shortly be commenced. The system to be adopted is the Thomson-Houston overhead, and the cost of laying the line, rearranging the Balls Bridge depôt as a power station, and the equipment of the line with electric cars, is estimated at about £70,000.

FACTORY AND OFFICE LIGHTING.—Messrs. Tickner and Partington have just completed the re-installation of the electric light throughout the extensive offices and mills of Spratts Patent (Limited) at Bermondsey, S.E. Incandescents are used throughout the mills, offices, and factory, and the plant also supplies current to a number of magnetic separators and a motor fan for ventilating the offices.——Messrs. Tickner and Partington are also fitting the new offices of *The Queen*, *Field*, and *Law Times* at Bream's-buildings, Chancery-lane, W.C., for electric lighting, and arrangements have been made for taking the current either from the City of London Company's mains or from the existing steam plant. When completed, nearly 1,500 16 and 32-c.p. incandescents and 17 arcs will be used.

FERMOY.—Communications from a number of electric lighting firms were read at the last meeting of the Town Commissioners, and it was decided to accept the offer of a conference with the representatives of the Electrical Installation Company on the subject of the electric light supply for the Fermoy district. The Commissioners also decided to accept the services of Mr. T. Tomlinson, engineer to the Bray Electric Lighting Company, to advise the Board on the subject.

FOLKESTONE.—The Corporation, at their meeting last week, had under consideration the scheme of electric lighting furnished by Mr. Medhurst, which he estimated would cost about £12,000. The scheme was explained at length, and, it was said, would embrace almost the same area as that previously submitted by Mr. Parker, but which was to cost £35,000. After a lengthy debate a new committee was appointed, with power to employ Mr. Medhurst to prepare plans, &c.

GLASGOW.—As a result of a friendly conference between representatives of the Watching and Lighting Committee of the Glasgow Police Commissioners and representatives of the Corporation Gas and Electric Lighting Committee, it has been agreed by the first-named body to pay the sum of £26 per lamp for arc lamps in use for lighting certain of the principal thoroughfares—George-square, and a temporary bridge over the Clyde near the harbour. There are, in all, about 130 of these lamps.

HEREFORD.—At the usual monthly meeting of the Town Council, on Tuesday, the Gas Committee recommended that having received a notice from the Great Western Electric Light and Power Company to apply for a Provisional Order to supply electric current within the Council's district, it was desirable that the Corporation should themselves undertake the electric lighting. The recommendation was referred to the Committee for consideration, with power to call a special meeting of the Council.

HULL.—Dr. Holder, Chairman of the Electric Lighting Committee, announced at its last meeting that the number of additional users of the electric light were more numerous than was at any time anticipated. He also announced that it might happen that the tramways would come into the Corporation's hands, and in that case it would be a question as to what power should be used, whether overhead or storage. He understood there was a new storage battery, which, from information he had received, was working satisfactorily in Paris. They were in a position to give such a battery a fair test on their own premises, and so form an opinion whether the cell was worth their consideration, and the Committee adopted his suggestion that their engineer should obtain a cell for the purpose of testing it.

KEIGHLEY.—A resolution in favour of an application to the Board of Trade for a Provisional Order to supply electric current within the borough has been referred to the Gas Committee of the Town Council.

KILLARNEY.—The Commissioners of Control of Public Lunatic Asylums, Dublin, have, owing to a report from their electrical engineering inspector (Mr. Walter Leake), made material alterations in the machinery at the Flesk water mills, which have been supplying the township of Killarney with electric current for the past six months. The wires, leading from the machinery in the mills across a field, then over the Flesk river across another field to the opposite road, where the connections are made, have been altered by a novel change. The wires, extending as above mentioned at a height of about 15ft. from the ground, have been put underground under the course of the river. These wires have been put into earthenware and under the river in metal pipes, and a telephone wire runs parallel with them, connecting up the works and offices in College-street.

LANCASTER.—It has been resolved to use 2,000-c.p. arcs for the street lighting.

LEEDS.—At the meeting of the City Council on Wednesday a resolution was adopted, by which arrangements are entered into with the Yorkshire House-to-House Company for the supply of electric light for the Town Hall and municipal buildings for a period of two years. It was pointed out that the installation at present in use at the Municipal Buildings constitute a nuisance to the neighbourhood, and that the vibration of the engines was objectionable. The cost per unit was 6·70d., whereas the House-to-House Company had undertaken to supply current at 6·57d. In moving the resolution Sir E. Gaunt said that the Council had spent a lot of money already, and that there was no doubt that if they had the work done by the Company for two years they would be in a position at the end of that time to tell whether it would be more advantageous for the Council to undertake the work themselves. Other speakers pointed out that the whole of the Council's plant was obsolete. Mr. Alderman Hepworth asked the Council to pause before it passed the resolution. He had had a great deal of experience in putting down the light in various parts of the country, and in no instance had a company supplied the electric light at the price originally given, not even within a considerable sum. The resolution was ultimately adopted.——Associated with the festivities to be held in connection with the Royal visit to Leeds, a 150,000-c.p. search light, manufactured by Mr. F. J. Boorland, of Leeds, is to be used, and preliminary experiments as to its power were made last night. The lens is 12in. in diameter. The chief interest in this lamp is in its capabilities as a means of conveying signals for the use of an army in the field, and the object of the preliminary tests is to show its capacity in this respect. In the tests last night a shaft of light was thrown across to Goole, where members of the Leeds Volunteer Corps were stationed, and signals were exchanged. The arrangements at Leeds were under the superintence of Mr. Nicholls, of the City Engineer's office.

LIVERPOOL.—At the weekly meeting of the Finance Committee a suggestion was made that the electric light should be substituted for gas at the St. George's Hall and the Municipal buildings; but the Committee did not think it desirable, "considering the great improvements continually being made in the electric light," to enter into any large expenditure at the present time.——The City Council at their last meeting considered the recommendation of the Watch Committee for the adoption of a new arrangement for lighting the city, by which it was proposed that at 11 p.m. a considerable number of lamps should be extinguished. Sir W. B. Forwood pointed out that the passing of such a resolution would be a most dangerous and hazardous step. They were asked to reduce the lighting of the town by one-half at the very time when all the great corporations of the country were introducing the electric light in order to provide better illumination, and at a time of night when it was most required, when the lights of the shops had been put out. Notwithstanding the opposition of many important members of the Council the Watch Committee's recommendation was adopted. It is estimated that a saving of £7,000 per annum will be effected.

LONDON GAS CHARGES.—Some time back we announced that a conference of delegates of vestries and various district boards in the London district was to be convened by the Hammersmith Vestry to consider the means of obtaining uniformity in the price of gas throughout the metropolis. This conference was held at Hammersmith this week, and representatives from Battersea, Fulham, Hackney, Hampstead, Islington, Kensington, Lambeth, Paddington, St. George's (Hanover-square), St. George's (Southwark), and Westminster were present. After some discussion a resolution was carried, that "the time had arrived when the anomalies in the charges for gas and the use of meters by the various gas supply companies should be removed, and that gas should be supplied at a uniform rate per thousand feet, with the free use of

Digitized by Google

meters." It was further resolved "that a Parliamentary inquiry should be held to inquire into the present management and working of the various gas undertakings, especially in regard to the question of the sliding scale of price and dividend."

MANCHESTER.—Mr. Alderman Gibson, at the last meeting of the City Council, in reply to questions put to him as Chairman of the Gas Committee, stated that the electric light installation was now being increased, and eventually, no doubt, the area would be extended, not only to Oxford-street, as suggested by a member, but to all the main roads in the city.

MIDDLETON (NEAR LEEDS).—This village is the property of the Middleton Estate and Colliery Company (Limited), and is composed of two mansions, a colliery, church, schools, chapel, and workshops necessary for the maintenance of the collieries and a population of about 1,200 persons. Mr. T. Harding Churton, of Leeds, has been called in by the owners to prepare a scheme for lighting the greater part of the estate by electricity, the generating plant to be situate at the colliery. The necessary work is now being carried out. A constant supply of current is to be provided for, the power being derived from a steam engine which is also used for ventilating the main. An underground concentric cable, designed by Mr. Churton and made by Messrs. W. T. Glover and Co., 2,300 yards in length, is to be used, and the dynamo is being made by Messrs. John Fowler and Co., of Leeds. The workwill be completed about the middle of November.

MOTHERWELL.—On Tuesday last the Police Commissioners discussed a report by Mr. Mavor, of Glasgow, dealing with the subject of the lighting of this district by electricity, which Mr. Mavor thinks could be introduced with good prospects of success. He estimates the initial outlay at £12,500, which would include the cost of obtaining a Provisional Order. As the Commissioners have been notified of the intention of a private company to apply for a Provisional Order, it was decided to adopt Mr. Mavor's report, and to take the necessary steps to carry out the scheme.

MUSIC HALL LIGHTING.—A sum of £550 was spent on electric lighting at the Canterbury Music Hall during the past year, and a further larger sum has been expended in lighting the Paragon Music Hall. These halls belong to the Canterbury and Paragon (Limited). The Chairman, at a recent meeting of the shareholders, stated that the Directors considered that the satisfactory result of the past year's working, in spite of the general falling off in music hall receipts, was largely owing to the policy adopted of brilliantly lighting the halls under the Company's management, and otherwise beautifying their property.

NEWCASTLE-ON-TYNE.—On Monday last a formal reopening was made of the Literary and Philosophical Society's premises after the lengthy closing for repairs and alterations consequent upon the disastrous fire which occurred at the centenary celebration. Mr. James Swinburne delivered a lecture on "Some Modern Electrical Experiments," which is the first of a series of twenty-one miscellaneous lectures to be given during the session. Lord Armstrong who, as President of the Society, took the chair, referred to the fact that on the previous occasion of his addressing the members the conflagaration referred to followed, and this was fancifully ascribed by some people to the pyrotechnic electrical experiments given on that occasion. In the course of Mr. Swinburne's lecture reference was made to the experiments of Mr. Nikola Tesla, and Mr. Swinburne was able to show a large Tesla coil lent by Mr. Mavor, of the Fowler-Waring Company, and which had been carefully and scientificially worked out by Messrs. Ionides and O'Gorman. This coil is by far the most powerful Tesla coil in this country, and enables a number of very striking experiments to be made. A cordial vote of thanks was awarded Mr. Swinburne at the conclusion of his lecture.

MILL LIGHTING.—The extensive Vulcan Mill, Bury, Lancashire, has just been fitted throughout for the electric light by Messrs. J. H. Holmes and Co. A trial recently made proved thoroughly satisfactory. A "Castle" dynamo of the latest type is used with a capacity for 1,160 16-c.p. lamps, and a second machine is used for the pilot circuit capable of supplying 230 16-c.p. incandescents. Two Marshall's engines are used.

THE NEW MAYORS.—Mr. Alderman B. A. Dobson, of the firm of Barlow and Dobson, machinists and engineers, and President of the Iron Trades Employers' Association, has been unanimously invited by the Bolton Town Council to accept the Mayoralty of that city for the ensuing year.

NEW SWINDON.—It has been decided to apply for a Provisional Order for lighting the district of New Swindon by the electric light.

THE "PATENT SOLICITOR."—Charles S. Hulser, trading as a "patent solicitor" at Temple Chambers, London, E.C., was convicted at the Mansion House, London, last week, for failing to carry out an undertaking to destroy a quantity of stationery containing untrue statements. Defendant claimed to be a patent solicitor, whereas he is not upon the rolls of the Incorporated Law Society. A fine of £4. 2s. was inflicted, or imprisonment for fourteen days. A distress warrant was issued.

PENRITH.—The extensive premises of Messrs. Hetherington Bros., general merchants, Corn Market, Penrith, have been lighted throughout by electricity. The outside lighting is effected by arc lamps, and 116 16-c.p. incandescents are used for the interior lighting. The generating plant consists of a 14 H.P. Stockport gas-engine, and an 80-ampere dynamo, supplied by Mr. Nawton, of Taunton.

PHOTO-PROCESS BLOCK MAKING BY THE ELECTRIC LIGHT.—Some very high candle-power Harp arc lamps are now being fitted by Messrs. Tickner and Partington, in Furnival-street, Holborn, W.C., for photo-process block work.

PORTSMOUTH.—The overseers have assessed the electric lighting works at £3,500, which means a payment in rates of nearly £1,200.

REDDITCH.—The Electric Lighting Committee some time back engaged the services of Mr. J. A. McMullen to prepare a scheme for, and to report upon the probable cost of, lighting the town by electricity. Mr. McMullen has prepared two schemes, one which would entail an outlay of from £7,000 to £8,000, and another which would cost from £13,000 to £14,000. The Committee have carefully considered these schemes, and believe that by making an equivalent charge for electric current to that now being paid for gas the smaller scheme would more than pay expenses, and that by the adoption of the second or larger scheme a profit of more than £1,000 per annum would result. The Committee, therefore, suggest that as soon as premises are obtained for from 1,500 to 2,000 lights a Provisional Order should be applied for, but that the whole question should be deferred until the election of the new Council.

SHIP LIGHTING.—The "Arundel Castle," a powerful steamer of 4,700 tons, now being built by the Fairfield Company, for the South African service of the Castle Line, is being fitted throughout with electricity.

ST. HELENS.—The Electric Lighting Committee of the Corporation have instructed Mr. Robert Hammond to report as to the best scheme to be adopted for the supply of electric current within the borough.

STRAND (LONDON).—The application by the Charing Cross and Strand Electricity Supply Corporation for leave to lay mains in the parish of St. Paul, Covent Garden, for the purpose of supplying electric current to Drury-lane Theatre, was discussed by the Strand Board of Works and refused.

SUNDERLAND.—A proposal to light the Museum and Library by electricity was before the electric lighting Committee of the Town Council at its last meeting. No definite decision was come to, the question being adjourned for further information as to probable cost, &c.

TAPE TELEGRAPH MACHINES.—The London Stock Exchange has recently decided to prohibit the use of the Exchange Company's tape machine by outside brokers, so far as the supplying of Stock Exchange prices is concerned. This has given rise to much discontent on the part of the fraternity affected by this decision, and an action was brought in the High Court, on Wednesday, for an injunction against the Exchange Company to restrain them until the trial of an action from disconnecting the plaintiffs with their Stock Exchange centre. Several points in the evidence were subsequently dealt with by the Lord Chief Justice, who ultimately declined to grant the injunction, but stated that the motion raised a question of very wide importance as to the liability of the Exchange Company to supply information to all members of the public without distinction or preference, as the Company were under licence from the Postmaster-General. No order was made as to costs, which were reserved till the trial of the main action.

TECHNICAL EDUCATION.—The London County Council have adopted a motion referring to the Parliamentary Committee and the Technical Education Board the preparation of a Parliamentary Bill, providing that a portion of the City Livery Companies' incomes should be allotted to the Council for the purposes of technical education in the Metropolis.

WELLS.—At the meeting of the Town Council, on Monday, the Lighting Committee reported that, in their opinion, it was desirable in the interests of the ratepayers to adopt the electric light for the city, and that a claim should be adopted and carried out by the Urban Sanitary Authority. It was decided to ascertain from other towns using the electric light the name of a competent expert to advise on the subject, and to report at the next meeting.

WOKING.—The Lighting Committee report that Messrs. New and Mayne anticipate lighting the streets by electricity according to their contract on October 8th.

WORKS LIGHTING.—The Aston Hall Brick and Tile Works, near Hawarden, and the iron and steel foundry works of Messrs. Maurice Donne and Morice, at Stevenson, N.B., are to be lighted by electricity.

Digitized by Google

WORCESTER.—The Electric Lighting Sub-Committee have recommended that the charge for electric current for motive power be fixed at 3d. per unit, and that a separate meter be used. It was explained by the Mayor that users of the electric current for motive-power purposes would then be supplied with power at a much cheaper rate than the gas company was able to supply them. The electric lighting mains are to be extended in order to supply current to applicants in College-street and Sidbury. It was stated that the equivalent number of 8-c.p. lamps at present wired was equal to 3,850, this, of course, being independent of the Waterworks pumping and street lighting. The churches of St. Michael and St. George, the Union Club, the Shire Hall, and other important public buildings were now lighted by electricity, and further extensions will be necessary in the immediate future.

LATIMER CLARK, MUIRHEAD AND CO. (LIMITED)

(*In Liquidation*).

The report of the receiver and liquidator in this winding up has just been issued, and discloses a most unsatisfactory condition of affairs. On the January 18th last, the date of the appointment of Mr. J. Worley as receiver and manager on behalf of the debenture holders, no funds have come into his hands as liquidator, as the whole of the assets are claimed by the debenture holders and other secured creditors. The Company's books had to be written up, and owing to complications that existed a long time was occupied in this work. Contracts had been entered into to the extent of fully £100,000 which still required to be completed, involving a considerable outlay for materials and labour, and it was necessary to finish them to prevent heavy claims for damages and loss of sums deducted as retention money. These contracts have now been completed, so far as they can be; but it will be some time before the balances outstanding in respect of them can be got in. The report gives an account of the formation of the Company in 1883, and the steps which were taken to obtain capital from time to time. In all about £19,300 was brought into the business up to 1886 in the form of debentures. In March, 1888, a second issue of debentures was resolved upon, and up to December, 1891, sums amounting to £10,900 were received in respect of the same. In February, 1889, other debentures for £12,000 were issued as security for loans, making the second issue £22,900 in all. The total due in respect of debentures and interest at the date of the stoppage was :—

1st issue.	Principal	£25,000 0 0	
	Interest	6,824 11 10	
			£31,824 11 10
2nd issue.	Principal	22,900 0 0	
	Interest	5,867 17 3	
			28,767 17 3
			£60,592 9 1

The turnover up to the end of last year appears to have been about £437,000. Some of the contracts seem to have been fairly profitable, but others showed disastrous results. The last balance-sheet was made up to June 30, 1893, and covered a period of eight months. It showed a gross profit of £3,501. 12s. on operations amounting to £38,600; but the net result was a deficit of £2,575. 11s. 10d.; after debiting establishment charges and £2,400 for interest on debentures and loans. The deficiency shown in the statement of affairs is £47,022. 9s. 10d. Adding the share capital £47,020, the total is £94,042. 9s. 10d., which is accounted for as follows :—

Losses on contracts, bad debts, &c., &c.......	£24,361 0 0	
" shares in various companies	4,027 1 4	
" patents	795 1 5	
		£29,183 2 9
Interest on debentures and loans, in excess of profits		24,638 2 4
Difference in valuation of plant, &c	13,467 16 10	
" " stock in trade	5,057 13 5	
" " premises, Regency-street	5,781 1 4	
Difference in valuation of furniture, &c. ...	914 13 2	
		25,221 4 9
Goodwill		15,000 0 0
		£94,042 9 10

No dividend has ever been paid on the shares. The Directors of the Company at the date of the stoppage were Mr. J. Latimer Clark, Mr. John Muirhead, Mr. E. Clapham and Mr. D. B. Hall. Mr. Clark and Mr. Muirhead had been on the Board since the formation of the Company, Mr. Clapham joined it in 1886, and Mr. Hall in May, 1890.

It was deemed desirable to sell the entire business and property, as a going concern, by private treaty if possible; but although special efforts were made no offer could be obtained. It was, therefore, decided to offer the plant, machinery, and stock in trade for sale by auction, which was done early this month, notice of the sale having been given to all the creditors. The net proceeds of the sale will not be more than £5,000. For the sub-leases of the premises in Regency-street there were no offers.

The gross liabilities of the Company are £101,728. 4s. 7d., of which £81,697. 10s. is expected to rank for dividend. The estimated assets amount to £34,675. 0s. 2d., of which a considerable portion is payable in debentures and shares of uncertain value, leaving a total estimated deficiency of £47,697. 10s.

A meeting of all the creditors is called for Thursday, the 11th inst., at three o'clock, at Winchester House, London, E.C., to consider the above report and statement of accounts, and to receive from Mr. Worley such further information as he is able to give as to the present position and past transactions of the Company. Mr. Worley adds that there does not appear to be any prospect of the unsecured creditors receiving any dividend.

COMPANIES' MEETINGS AND REPORTS.

Brush Electrical Engineering Company (Limited).

The fifth annual general meeting of this Company was held at Cannon-street Hotel on Monday, October 1st, under the presidency of Mr. J. B. Braithwaite, jun.

The SECRETARY (Mr. B. Broadhurst) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: In moving the adoption of the report I do not think I need detain you more than a very few minutes on this occasion, as the past year with the Brush Company has been one of continuous employment in our factory and one of great commercial prosperity, considering the very keen competition we have had to meet with in our business during the period under review. I will deal first with the balance-sheet, and then with one or two matters which will, I think, interest you with regard to our present position as a manufacturing company. If you turn to the balance-sheet you will see that there has been no change in the capital issued in the past year, and the shares and Debenture Stock issued remain the same. There is an increase in the item of creditors which is balanced by a corresponding increase in the item of debtors, both of which increases are due to the extended business which the Company has done during the past year, an increase amounting to about 50 per cent. The next item is loan from bankers on security, £25,000. You may ask how it is we have arranged for this overdraft instead of issuing further capital in view of the fact that our Debenture Stock is at a good premium, and that our Preference Stock is also at a premium. The answer is that we do not require any additional working capital. The reasons which made it desirable for us to arrange an advance from our bankers are reasons of a temporary character only. There are three reasons. One is the increased overturn of the business, another is the large amount of money that we have locked up at the present moment in retention funds connected with the municipal contracts we are executing. I do not know whether the shareholders are aware of it, but in undertaking these municipal contracts it is usual for a provision to be inserted that a considerable sum of the total amount of the contract shall be retained in the hands of the Municipality until the plant has been set to work, and been running to the satisfaction of the Borough Engineer for a period of three months or six months as the case may be. The same retention clause exists in respect to the large contract we have with the City of London Electric Lighting Company. Therefore, when you see on the credit side of the balance-sheet that we are owed £158,000, I may say that something like £50,000 or £60,000 of that is represented by this retention money, all of which will come in, and a good deal of it very shortly. When it comes in there will be no further necessity for us to have credit from our bankers, so that to issue capital for a purpose like this would be only unduly burdening ourselves. We also hold nearly £43,000 of shares and debentures in other companies. It is probable that during the present year at least half of that amount, and possibly more, will be turned into cash, which would again, by itself, enable us to repay this loan and also have working capital in hand. I think the shareholders will agree with me that under the circumstances it is much better to arrange for the accommodation we require temporarily from our bankers rather than to permanently increase the charges on the Company by issuing fresh capital, and I hope that the shareholders will endorse the action we have taken in this matter. The next item requires a little explanation. If you look on the credit side of the balance sheet you will see an amount of £9,000. Shareholders who have been in this Company for some years will probably remember that for two or three years in succession we wrote off a lump sum of £3,000 out of our profits from the item of property, patents, and goodwill. This was written off in a general way, without reference to any particular item, and appeared in our books as a sort of inner reserve fund. I had a conversation with Messrs. Cooper Brothers, our auditors, this year on this subject, and I pointed out how undesirable it was that this inner reserve fund should exist in our books unknown to our shareholders, and I said that, personally, I should prefer that our balance-sheet should show our position to the shareholders to the fullest possible extent. I therefore suggested that we should bring that £9,000 back on one side, and show it as a reserve against depreciation on the other. You will therefore see that we have brought that figure of £9,000 back, and in the past year we have deducted from it the balance of the cost of the Manchester and Cardiff stations closed during the year, amounting to £3,614, leaving us with an available reserve for depreciation of property, patents, and goodwill of £5,385, in addition to the other reserve, which now amounts to a little over £1,000. The shareholders will therefore see exactly our position with respect to that item. With reference to the closing of the Manchester and Cardiff stations, I suppose we must say that that is the fortune of war. In both those cases the Brush Company pioneered the electric light. At Cardiff we had a station running for a considerable number of years, and we did the work so well that the Corporation there said that it was a good sound business, and that they would do it themselves. When, therefore, we applied for a Provisional Order, we found that our supply had been so excellent

Digitized by Google

that we could not get the Corporation to consent to our having an Order. The same thing occurred at Manchester, where we had a small supply station which had been furnishing current for some years to hotels, &c., in the neighbourhood. When we applied for a Provisional Order the Corporation said, "No, you have done the work well; and shown us that it is quite easy, so we intend to do it ourselves, and keep the profit." There was therefore nothing for it under the circumstances but to close down those stations, sell our property, and write the thing off; and the difference between the cost of these stations, as it stood in our books, and what we realised for them has been this sum of £3,614, which we have written off our depreciation reserve fund. Those two matters are now cleared up, and I need not state that in the present condition of the electric lighting industry there is no necessity for us to pioneer any further stations. We have set the example and done the pioneering work, and municipalities throughout the country are now convinced that it is to their interest to do the work themselves; and I am glad to say that in many cases they are coming to the Brush Company, as the people who are most competent to supply them with the plant they require. On the credit side of the balance-sheet you will see that the item of property, patents, and goodwill is increased by this sum of £9,000, and it is further increased by the additions which have been made during the year to plant, amounting to £3,710. This represents virtually the additional capital expenditure we have incurred in the past year, and it has been almost entirely incurred for additional tools in order to enable us to deal with the large amount of central station plant that we now have orders for. It has also been partly incurred for additional shops at Loughborough, where we have, I suppose I may say, the finest electrical works in the United Kingdom. If any shareholders would like to have an opportunity of visiting our works at Loughborough, we should be happy to give them every facility for seeing the property in which they have invested their money if they will drop a line to the Manager. We have deducted for property and plant disposed of during the year, £5,237, and the usual sum for amortisation of lease, £733; and we bring out then our property, patents, and goodwill at the figure of £287,084. Then we have our stock—goods in hand in process of manufacture, work in progress, and materials in London, at Loughborough, and other places, £114,681. I am very happy to be able to say, as I think I said the same at our meeting last year, that none of the plant represented by that £114,681 as in course of manufacture is being manufactured for stock simply to keep the men employed and our works going. All of this work is in execution of orders that we have received. With regard to the item of debtors, I have mentioned the large sum that we are now owed of £158,691; and then we have our cash at bankers and in hand amounting to about £13,000; share and debentures in other companies about £43,000; and liquidators' balances and suspense accounts £2,110. The balance of foreign and colonial branches accounts stands at £76,258. That gives us a net result, after paying our interim dividends and charging the interest on our Debenture Stock, for the whole year of £15,938, out of which we shall propose, if you approve this report and balance-sheet, that £12,150 be appropriated to paying the second half-year's dividend on the Preference shares, and a dividend on the Ordinary shares at the rate of 5 per cent. per annum, carrying forward £3,788. Probably someone will ask why we do not propose the same dividend as we paid last year, as we have earned it. It is quite true that we have earned it; and paying 7 per cent. per annum instead of 5 per cent. would absorb £2,700, and we could pay that and still carry forward £1,088. It is not unreasonable, therefore, for you to ask whether we have any special reason for not doing so. We have no special reason except that the balance-sheets published by some of our competitors—two of whom, not having even earned their Preference dividends out of trading profit, were of such a character that we thought the present was the psychological moment to increase the amount carried forward. We thought that this was an opportunity which might never occur again, and I hope you will approve of this course, because in an industrial concern like ours you cannot be in too strong a financial position. I believe you will find that the fact that we are in such a solid financial position as to enable us to carry forward so large a sum will do the Company not harm but good. We do not, however, intend to pile up the amount carried forward in this way. If we have another year like this, I hope that we shall be able to pay a dividend of 5 per cent., which I think we will settle on as our regular dividend, and a handsome bonus besides; but I cannot prophecy until the end of the financial year. If you turn to the profit and loss account you will find that our gross profit this year was £57,157, as compared with £49,405 in the previous year. You will therefore see that during the past year our gross profit has improved by £8,000, which, in view of the fact I have mentioned before of the exceedingly keen competition which there has been for these tenders for Municipal stations, cannot, I think, but be considered extremely satisfactory; and in my view it reflects very great credit on our managers, officers, and staff generally, all of whom have worked so loyally and heartily in the interests of the Brush Company in the past year. On the other side of the account the standing charges show an increase of about £2,000. You cannot do 50 per cent. more business without some additional expense. You are aware that last year we wrote off £1,300, the bulk of the cost of the removal to Loughborough. The final concentration of our work there has taken place at an expense of £632, which we propose to write off out of revenue, the same as we propose to do with the cost of removing from the Hammersmith works. We have spent nearly £4,000 more on buildings and plant. This expenditure assures us that our engineers and other officers keep our property in first-rate condition. The net result of the profit and loss account is that there is a profit, after paying the Debenture interest, for the shareholders of £27,280. There is nothing calling for special attention in our foreign business. In Australia the business during the past year has been very much reduced and hampered, owing to the crisis through which the Australian Colonies have passed; but I think the shareholders will be well satisfied with the gentlemen who are managing our business out there in view of the fact that, notwithstanding all this financial depression, the amount of bad debts they have made is less than £50. With respect to our Vienna business, that has made satisfactory progress in the last year. The quality of the work turned out from there is extremely high. Our engineer, Mr. Kremenezky, is a very energetic and talented gentleman, and I think your interests are well served by him in Austria and on the Continent generally. All the plant he turns out is of first-class quality, and the arrangements we have made for the financial management of the business between London and Vienna have proved satisfactory. During the past year the Vienna business has shown us a fair return on the amount of capital invested in it, and I think it is a business that is steadily improving. There is a new item in our balance sheet—namely, the Bonus Fund "Trustees' a/c" in connection with the employés' bonus scheme. The shareholders who have attended these meetings for some years are aware that in 1887 we thought it right to adopt some scheme between the Company and its employés, by which the latter should have some share in the prosperity of the Company, believing that such a course was in their interest as well as in our interest, as attaching them more firmly to us, and encouraging that strong feeling of loyalty and *esprit de corps* which, in such an undertaking as this is of very special value. This scheme has very much extended since it was established. In 1887 the number of participants was only 13, and the amount distributed was £250. We began by making our highest officers participants, but we have gradually extended the scheme downwards. In 1890 there were 25 participants, and the amount distributed was £730; in 1891 55 participants, and the amount distributed was £1,313; in 1892, 67, and amount distributed £1,961; and last year we felt that we must make a stride forward, and include a much larger number of the men in our employ. In doing that it became necessary to draw up a trust deed and appoint trustees, and in 1893 the number of our employés who participated in the scheme was 163, and the sum distributed was £2,488. The trustees consist of the Chairman of the Company from time to time, the two managers, and our works manager at Loughborough. The sum we have had to deal with has been £2,190, out of which we have paid out £872. We have invested £1,196 in the purchase of £889 Four per Cent. Midland Railway Preference Stock, which forms the provident and reserve fund provided by the scheme. I think this disposes of all the points which arise with respect to the balance-sheet, but I shall be very happy to answer any questions which the shareholders may wish to put respecting it. With regard to the general prospects of the Company, it may interest the shareholders to know that during the year the stations we have erected for the municipalities of Lancaster, Huddersfield, and Hanley, have been opened for work. We have also completed the installation for the Duke of Norfolk at Arundel Castle. We have now in hand the fitting up of the Central Station at Worcester, and the works are also in hand for the municipality of Leicester, and these works will be opened before the end of the year. We have also work in hand for the Dover Company. With respect to our City of London contract, you will remember that when we took that contract the largest size of dynamo machine we had made was one of 100 kilowatts, capable of supplying about 3,000 lights. The contract provided for our manufacturing machines of four times that size, and at our meeting the year before last I said that we had successfully manufactured a machine of 200 kilowatts, which proved to be capable of supplying, not 6,000 lights, but nearly 7,500. I told you last year that the first two of the larger machines had been built and erected in the City Station. Those machines were specified for 400 kilowatts, and turned out equal to 500 kilowatts. Each of the machines which we have furnished to the City of London Company is capable of supplying current for 15,000 lights, and the City of London Company has now six of these 15,000 light machines. Three more are on order, and are now in course of manufacture. Each machine supplied by us has exceeded the specification, as proved by the tests taken. The specification stipulated that the combined efficiency of the engines and dynamos should not be less than 80 per cent., and the tests made by Professors Kennedy and Thompson gave a result of 83 per cent. The regulation of the machinery was to be within 10 per cent., and the result was well within that figure. In every case our work has not only come up to, but has exceeded, the requirements of the specification. I think these facts deserve a word of praise from me as Chairman of the Company (and I hope that the shareholders will endorse them) in recognition of the abilities of the technical officers by whom these results have been attained. Our engineer, Mr. Raworth, is responsible for the design of the engines; and our electrician, Mr. Mordey, is responsible for the dynamos; and the fact that these gentlemen should have made designs of machines four times larger than anything previously built, and that those machines should have been built from those designs, practically without modification, is very high testimony to the capabilities of those gentlemen. Although we have had some very large orders from the City of London Company, we are still expecting further orders for another £100,000, and judging from the progress made we shall not have to wait long, for the applications for lighting in the City continue to increase. I do not think it will be a breach of faith to mention that the applications received for the light last week alone exceeded 4,000 in number. Then, with respect to the County of London Company, which we have formed during the past year, we were careful to send a prospectus to every one of the Brush shareholders, wishing to give them an interest in a company which we believe will turn out as successful in its way as the City of London Company. They, however, only responded to a very small extent. I do not think the prospects of the County of London Company are one whit less favourable than those of the City of London Company. The County of London Company hold the district of St. Luke's, joining on to the City boundary, and running up to the Angel, Islington, and the districts of Clerkenwell and Wandsworth. The Bournemouth station is theirs, which already supplies 18,000 lamps, and they also have a station at Dover. In addition to these the Company has secured the outfall o

Digitized by Google

Lake Windermere, which is the finest piece of water-power in the kingdom, equal to 40,000 H.P. The Company is taking the necessary steps to acquire powers to supply an area of ten miles from Lake Windermere, and the Brush Company expect from the County of London Company orders to the extent of something like £1,000,000 in the next few years, and therefore we feel a beneficial interest in their progress. It is impossible to prophesy the financial results of the current year, but so far we have every reason to be satisfied. Our works are employed to their utmost capacity, and we have orders in hand that will keep us employed to the end of the year, while additional orders continue to come in at a satisfactory rate. I think, therefore, that we shall not have a less satisfactory balance-sheet next year than we have this. I now propose

"*That the report of the Directors and statement of accounts to June 30, 1894, now presented to the shareholders, be received, and that the same be hereby adopted.*"

Mr. B. H. VAN TROMP seconded the motion.

Mr. BOYS thought there was a middle course between paying a dividend of 5 per cent. and 7 per cent. on the Ordinary shares, and that was 6 per cent. He had every confidence in the Company as he had always had, and he had been very pleased to hear the remarks of the Chairman.

The CHAIRMAN said there was no reason why they should not pay a dividend of 7 per cent. per annum for the past half-year on the Ordinary shares; but at the same time he thought the shareholders would agree that the present was an opportunity of strengthening their position which they ought not to lose sight of.

Mr. SEWARD asked if the reserve fund was invested separately, or whether it was in the business.

The CHAIRMAN: The reserve stands in our books against our property patents, and goodwill.

The resolution was unanimously carried, as were also resolutions for confirming the payment of the interim dividend at the rate of 6 per cent. per annum and 5 per cent. per annum respectively on the Preference and Ordinary shares for the six months to December 31st last, and for the dividend on the Preference shares at the rate of 6 per cent. per annum, and on the Ordinary shares at the rate of 5 per cent. per annum for the six months ended June 30th.

Mr. Sanderson and Col. F. G. Steuart were re-elected as Directors, and Messrs. Cooper Bros. and Co were re-appointed auditors, and, after a vote of thanks to the Chairman for presiding, the proceedings terminated.

The Fusion of French Cable Companies.

Extraordinary general meetings were held last week of the two French Cable Companies it is proposed to amalgamate—that of the Société Française des Télégraphes Sousmarins on Thursday, and that of the Compagnie Française du Télégraphe de Paris à New York on Saturday. The meeting of the former Company was under the Presidency of Admiral Caubet, the Chairman of the Company, and the resolutions approving the fusion, subject to the Government authorisation, were carried.

The Directors of the Compagnie Française du Télégraphe de Paris à New York, previous to the meeting forwarded to the shareholders a report, of which the following is a translation:—

"The Board of Directors you elected last year would have ill comprehended its mission if it had contented itself with following in the steps of its predecessors and with prolonging indefinitely a situation which for fifteen years has meant for you not only the absence of dividends, but (being without a reserve fund) a diminution, each year more marked, of the value of the property which represents your capital. Naturally, our first duty was to re-establish order on the Board, reduce expenditure, increase as much as possible the traffic, and watch the course of litigation in progress. But we know well that with the best administration a cable placed in conditions like ours—a single cable, without feeding lines, without return traffic—could not possibly realise profits sufficient to lay up a reserve and to distribute a dividend to the shareholders. You have had the situation under consideration at your meetings of 1890, 1891, and 1892—your opinion in 1891 being unmistakable, when, in view of the establishment of a cable from Puerto Plata to New York, you passed a resolution that an issue of debentures sufficient to produce the sum of 12,000,000fr. should be made; and so the junction of our cable with the French system of the Antilles, and the search for a strong and durable support, became rightly the chief object in view. This result, which your isolated efforts were unable to realise, an understanding with the Société Française des Télégraphes Sousmarins might one day permit you to realise; we have, therefore, thought it our duty to pursue the realisation of this object, which appeared to us to be of very great importance for both Companies.

"Separated as they are to-day, left to their own traffic resources in the face of a very powerful combination, they can neither increase nor prosper. The Compagnie Française du Télégraphe de Paris à New York connects France and America without possessing in the latter country any interest capable of bringing traffic to it; while the Société Française des Télégraphes Sousmarins, although owning a system extending over nearly 7,000 kilometres in a region of the New World where it has important monopolies which have a long period yet to run, can only communicate with France and Europe through cables belonging to foreign companies, which have the greatest possible interest in preventing the development of its traffic. To form of these two companies, each of which would be so well the complement of the other if they were combined, one great French Telegraph Company, capable of giving to the correspondence between France and the three Americas the independence and security which it calls for, is the aim of the project now submitted to you.

"In considering this project it is not only a question of the pure and simple union of the present receipts of the two companies, but of the effective junction of the two systems, which, once combined, should lead to an important increase in receipts. This consolidation of the two systems could be effected by the laying of a cable between the Antilles and North America, as in the scheme which you have approved at former meetings. This connecting link once laid, the Company would transmit its traffic by its own cable, and would thus retain the receipts from correspondence exchanged with the countries served by the Société Française des Télégraphes Sousmarins which have now to be divided with the intermediary companies. On the other hand, messages for Europe originating on the system of the Société Française des Télégraphes Sousmarins cross the Atlantic by Anglo-American cables, and not by the Pouyer-Quertier cable. This traffic, which is now taken to Cuba by an English Company whose interests are bound up with those of the Anglo-American lines, will be sent by the P.-Q. cable as soon as a connecting line has made the system of the Sousmarins Company independent of foreign companies. Besides the traffic now existing, which it is essential should go over our lines, the amalgamation of the two systems should lead to a very important augmentation of income, the principal sources of which would be: (1) The traffic between Brazil and the whole Atlantic coast of South America and North America, which now goes *viâ* Europe, crossing the Atlantic twice; (2) The traffic between Europe, Cuba, and the greater part of the Antilles, which would find in the new line a much quicker and cheaper route. Under these new conditions, it will be necessary to consider the question of laying a second transatlantic line between France and the United States, which would not only give security, but would be required for the increased traffic. It is not necessary to say that the laying of a second cable would, even in the conditions which now exist, ensure our line from interruption; but it would not bring any increase of traffic to return the capital which would have to be expended. No project of this kind will stand serious examination in view of the actual condition of our Company's finances.

"We have every reason to believe that the constitution of a grand French system such as we have indicated would be viewed with favour by those in authority, and that the great Company of which you will form a part, if you approve the proposals we make, will receive from the Government support which will permit the realisation of the programme laid before you. The progress of the negotiations has not permitted us to bring this question before you since your last meeting; besides, the litigation with the Anglo-American Company had not then been concluded, and we were precluded from touching on that subject. You are aware of the result of that litigation. The principal demands of our opponents have been rejected, and we wait with confidence the result of the expert inquiry, which is limited to the period 1886-1891. We have to bear the costs. But, since the month of May, the question occupying our attention has made a decided advance, and we find ourselves in presence of solid proposals, which it was our duty to submit to you at the earliest moment.

"You have been furnished with the terms of the provisional agreement between the Boards of Directors of the two Companies, the Compagnie Française du Télégraphe de Paris à New York and the Société Française des Télégraphes Sousmarins, now submitted for your ratification; this will have given you the financial side of the project, and we here give an analysis:—The reconstituted Company will have a capital of 24 million francs, composed thus: Reduction of the capital of the Société Française des Télégraphes Sousmarins from 11 million francs to 7,300,000fr.; capital representing our Company, 14,000,000fr.; shares subscribed for at par by a group of financiers to the amount of 2,700,000fr., which sum would be utilised for carrying out the scheme. To effect this, you will have to vote the liquidation of your Company, and its liquidators must have authority to transfer its property to the Société des Télégraphes Sousmarins at a total value of 14 million francs, which it will receive in fully-paid shares of the Société Française des Télégraphes Sousmarins, reconstructed with a capital of 24 million francs. The number of share warrants will agree with the value of the ceded property, and the exchange for the shares of our Company will be effected by the liquidators after the liabilities are disposed of.

"The estimates of the value of the property of the two Companies appear to us to be reasonable and fair. The American system of the Société des Télégraphes Sousmarins will be represented in the new amalgamation by 14,300,000fr.—7,300,000fr. in shares, and 7,000,000fr. in debentures. This valuation does not appear to us to be excessive. The Company's system in the Antilles and in South America extends over 6,754 kilometres. Its total cost has been 10 million francs, including the concessions, the greater part of which, as we have said before, ensure for many years an exclusive monopoly. In addition, the Société des Télégraphes Sousmarins possesses, by contracts, subventions, and traffic guarantees, a sum of 355,000fr., which will be sufficient to pay the interest on the debentures. We have, therefore, had to consider whether this amount of 14,300,000fr., the estimated value of the system of the Société des Télégraphes Sousmarins in the new amalgamation, corresponded with that of our own property. The system of the Société des Télégraphes Sousmarins, of whose value we had to make a comparative estimate, comprises a group of cables, the first of which was only laid in 1888, their average existence not exceeding four years. If we suppose, following accepted calculations, that they should last 25 years, it is evident that they are almost as good as new. The amount of 14,300,000fr., which represents their estimated value, gives them an average worth of 2,117fr. per kilometre. The same calculations respecting our cables gives an average of 2,163fr. per kilometre for lines which have been laid more than 14 years, and whose initial value has evidently suffered a sensible depreciation. We have also had to recognise the fact that the Société des Télégraphes Sousmarins holds in certain countries privileges which relieves it from all danger of opposition, while with us rivalry is a permanent menace.

"Our property, consisting of our submarine and land lines, our steamer, cable in store, material—everything constituting our assets—has been estimated at 14,000,000fr. Giving our cables an original life of 25 years, and reckoning its initial value at 34,000,000fr., its present worth comes out at about 13,600,000fr.

Digitized by Google

"In valuing the property of the Société Française des Télégraphes Sousmarins, we have left entirely out of the calculation the New Caledonia cable, which was recently laid and is worked by that Company under the law of March 23, 1893. This cable, which is 1,500 kilometres in length, is the outcome of an absolutely distinct operation, and was provided for by the issue of special debentures, the interest on which is guaranteed by the French and the Australian Governments. Receipts are guaranteed of 300,000fr. after deduction of 60,000fr. for cost of working. It is anticipated that the investment of these debentures will exceed the charges they were issued to meet. The two companies have also had to take into account, in making this estimate of value, the appreciation of the new shares taken at par for the sum of 2,700,000fr.

"The meeting of shareholders of the Société Française des Télégraphes Sousmarins will take place before yours. The resolutions passed by them will be communicated to you, and it will then be for you, in your turn, to vote on the preliminary agreement, which we ask you to confirm, relying on your wisdom to take care of your own interests."

The *Bulletin de l'Electricité et de la Télégraphie* has voiced the opposition offered by some of the shareholders to the proposed fusion, and its last issue contained a long reply to the above report, dealing *seriatim* with the points raised, and stating that the Minister of Posts and Telegraph had been petitioned to withhold his consent to the amalgamation. The *Bulletin* also accused the Directors of a desire to take no action in obtaining from Messrs. Siemens Bros. and Co. an amount of nearly 11 million francs, which (according to the *Bulletin*) is due to the Company under the following circumstances:—By the terms of an agreement made in 1878 between M. Pouyer-Quertier and Messrs. Siemens Brothers, the latter were to establish two telegraphic communications between Europe and North America—one from France to the United States, and the other from England to Canada—and to provide a fully-equipped cable steamer; the total cost to be $44\frac{1}{2}$ million francs. The first cable and a portion only of the second (St. Pierre-Cape Cod) have been completed, and the cable steamer provided, of a total value of 12,465,500fr.; but Messrs. Siemens Bros. having received from the Company 33,334,000fr., it is claimed by the dissentient shareholders that the balance should be refunded by them to the Company.

At the meeting on Saturday, M. Etard, a Director, presided, in the absence of M. Lefaivre, the Chairman of the Company, and proposed the resolutions approving the winding up of the Company and the transfer of its assets to the Société Française des Télégraphes Sousmarins. He said that the Government had intimated that the necessary authorisation would probably be granted if the shareholders of both companies voted the amalgamation; and that, with reference to Messrs. Siemens Brothers, negotiations were pending with that firm, and that any sums recovered from them would be expressly reserved for the shareholders of the P.-Q. Company. A lengthy discussion ensued, but in the end the resolutions were passed almost unanimously.

CITY NOTES.

AFRICAN GOLD RECOVERY COMPANY (LIMITED).—At the meeting of the shareholders of this Company held last week, the Chairman said that the results obtained from the MacArthur-Forrest process, of which they are the owners, were eminently satisfactory, and resulted in the production of from 30 to 50 per cent. more gold than was obtainable before the discovery of the process. With respect to the Siemens and Halske process now being adopted to some extent in South Africa, this was, he believed, a process based upon the MacArthur-Forrest discoveries, and was being worked with some trifling addition.

ALUMINIUM COMPANY (LIMITED).—The profit for the year ended June 30th enabled the Directors of this Company, after providing for fixed charges, and allowing for depreciation in plant and buildings, to declare a dividend of 5 per cent. for the year on the "A" shares, carrying forward £1,475.

BIRMINGHAM CENTRAL TRAMWAYS COMPANY (LIMITED).—A meeting is to be held on the 10th inst. at the Queen's Hotel, Birmingham, to discuss a resolution to reduce the capital of this Company from £500,000 to £300,000. A circular accompanies the Directors' notice of the meeting, pointing out that very large sums of money have been spent, some of them most improvidently, which are no longer represented by the assets of the undertaking. A portion of the large sums referred to was spent in the provision of locomotive steam power for working a portion of the Company's system; but the Directors' report that the economies which were anticipated by many eminent engineers have not been attained.

BRITISH THOMSON-HOUSTON (LIMITED).—Mr. Ernst Thurnauer, General Manager in Europe of the General Electric Company of the United States, and a Director of the Compagnie Française pour l'Exploitation des Procédés Thomson-Houston at Paris, and of the Union Elektricitäts Gesellschaft at Berlin, has joined the Board of this Company.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended September 30th, were £881, as against £798 in the corresponding period of 1893, being an increase of £83. The total receipts for the half-year amount to £11,118, as against £10,479 for the corresponding period of 1893, an increase of £639.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of September, are £2,700, as compared with £2,880 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of September, 1894, amounted to £1,898, as against £1,865 in the corresponding period of last year.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend of 2s. per share free of income tax, being at the rate of 2 per cent. per annum, for the quarter ended September 30th, such divided to be payable on and after the 24th instant.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the month of September, 1894, amounted to £57,368, as against £55,997 in the corresponding period last year, an increase of £1,371.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of September, 1894, amounted to £40,178 and to £39,339 in the corresponding period of last year, being an increase of £839.

ENGINEERING AND GENERAL CONTRACT CORPORATION (LIMITED).—At the adjourned meeting of the shareholders of this Company, on Wednesday, the report of the Committee of Investigation, referred to in our last issue, was adopted, but a poll was demanded by the Directors.

W. T. HENLEY'S TELEGRAPH WORKS COMPANY (LIMITED).—Warrants were on Saturday posted for a dividend on the Preference shares of this Company for the half-year ended June 30, 1894, at the rate of 7 per cent. per annum.

MILDE TELEPHONES.—This week the public have been invited to subscribe for a first issue of 5,000 Seven per Cent. Cumulative Preference Shares of £1 each in the Mildé Telephones and Electric Supply Company (Limited), which has a capital of £20,000 in 15,000 Preference and 5,000 Deferred shares of £1 each. The prospectus states that the Company is formed with the object of acquiring the sole right granted to Mr. M. Kotyra by Messrs. Mildé, Sons and Co., of Paris, to all their improved telephones in Great Britain and Ireland and the English Colonies, and to establish local, provincial, and private telephone exchanges, &c., &c. Many claims are made for the Mildé telephones, one being that they are more simple in construction than any other telephones in the market. No date is given for the closing of the lists, and those requiring prospectuses will doubtless obtain copies at their leisure. The Deferred shares will not be entitled to any dividend until these Seven per Cent. Preference Shares have received their full dividend, and any surplus is to be divided between the Preferred and Deferred.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts for this Company for the two weeks ending September 30th were £1,647, as compared with £1,769 for the corresponding period of last year. The receipts for June, estimated at £4,460, realised £4,530.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended September 28th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £3,395.

WESTERN UNION TELEGRAPH COMPANY.—The following is the report of this Company for the quarter ended September 31, 1894:—The condition of the Company at the close of the quarter ended June 30, 1894, was as under:—

Surplus April 1, 1894, as per last quarterly report		$6,937,992 68
Net revenues, quarter ended June 30, 1894		1,455,073 86
		$8,393,066 54
From which, deducting for dividend of $1\frac{1}{4}$ per cent. paid July 16th	$1,185,037 50	
Interest on bonded debt	220,404 50	
Sinking funds	19,991 00	
		$1,425,433 00
Less—Portion of Sinking Fund for the bonds of 1900 (which was set aside previously) returned to the Company by the Sinking Fund Trustees, because of the drawn bonds not being presented for redemption	40,000 00	
		$1,385,433 00
Left a surplus July 1, 1894, of		$7,007,633 54
The net revenues of the quarter ended September 30th based upon nearly completed returns for July, partial returns for August, and estimating the business for September, will be about		1,800,000 00
From which, appropriating for—		$8,807,633 54
Interest on bonds	$223,500 00	
Sinking funds	20,000 00	
Purchase of the telegraph lines and property of the American Rapid Telegraph Company, with 5,500 shares of capital stock, issued out of the increased stock authorised by the stockholders on October 12, 1892	550,000 00	
		793,500 00
		$8,014,133 54
It requires for a dividend of $1\frac{1}{4}$ per cent. on the capital stock issued		$1,192,000 00
Deducting which leaves a surplus, after paying dividend, of		$6,822,133 54

In view of the preceding statements, the Committee recommend the payment of a dividend of $1\frac{1}{4}$ per cent. on the capital stock of the Company on October 15th.—The dividend may be collected through any bank on or after the 15th inst.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 856. Vol. XXXIII. FRIDAY, OCTOBER 12, 1894. PRICE FOURPENCE *Annual Subscription (U.K.), 19/6*

NOTES.

Owing to an unlucky breakdown of some of the switching machinery at the Bankside station, the whole of the supply, with the exception of that for the street arc lamps, had to be stopped for several minutes between two and three o'clock on Tuesday afternoon. The circumstance was rendered all the more unfortunate by the fact that the City was plunged in a fog at the time, and every available artificial light was in use. It seems that the cause of the breakdown was primarily due to the earthing of the switch connections of some of the exciter dynamos. This caused two of the Brush alternators to lose their field, and thus to short-circuit the mains, crippling the armatures by the mechanical displacement of some of their coils. It was considered advisable to shut down the whole station, with the exception of the arc machines, and to overhaul the plant. The trouble was quickly localised and remedied, and the station was in full swing again by a quarter to three o'clock. We understood that an improved switching gear had been invented by Mr. Mordey, for the express purpose of preventing accidents from arising when an alternator, in parallel with others, loses its field. This apparatus was described in *The Electrician*, Vol. XXXII., page 457. We do not know if it was in use at the Bankside station at the time of the accident just referred to; but we remember that it was to have been introduced there immediately after a similar accident which took place some months ago. Mischief must inevitably result from this mishap to other supply companies who have never had a hitch of any sort, and with whom even a flicker is extremely rare, and even to the whole industry, by shaking the confidence of the public in electric lighting.

A correspondent this week calls attention to one of the causes of flood in rivers which might be used for water-power purposes, and advocates as a remedy the construction of reservoirs, in which the storm water might be stored instead of flowing in a swollen and destructive torrent to the sea. We quite agree with our correspondent that "the whole question of conserving our water is fast becoming a national one." But, in the first place, we do not think the question is becoming a national one on account of hydraulic power; but because of the far more vital question of town water supply for domestic use. Nor do we think there is any practical value in the idea that the reservoirs might be built on the capital saved from destruction by floods. The problem would be to get the owners of property to see the matter in this light, especially if they were to have no direct interest in the water-power conserved. To the whole of the proposition put forward by our correspondent it may be urged, that if the civic and municipal authorities of the present day find such great difficulty in adequately meeting the reservoir problem for ordinary water supply, how much more difficult must it be to attack that problem solely in the interests of hydraulic power?

We reprint in our columns this week some remarks which have been made by our esteemed contemporary the *Engineer* on the governing of electric light engines. We do so, not because we are in complete agreement with the conclusions there expressed; but because we feel that this is a matter to which the special attention of electric light engineers ought to be called. Our contemporary sums up the difficulty very clearly; but we doubt whether the remedy it proposes would entirely meet the case. That there does exist the need for more prompt arrangements for keeping the electric pressure steady, every blink in the lights of non-storage systems amply shows. These blinks are, unfortunately, too frequent to admit of being called "accidental"; they are contingent upon the present modes of governing and regulation. It must not be overlooked, however, that only a part of the fault lies in the engine. There is the instantaneous change in the feeder-drop, which also tends to cause a blink whenever a sudden change of load occurs. It is impossible to make the engine governor responsible for an absolutely constant and non-fluctuating pressure on the lamps, if there is a drop of several volts between the lamps and the machines. The regulation to meet this is essentially electrical; and, in alternate-current systems, it is effected by hand in a manner which cannot possibly eliminate blinks.

As regards the part of the problem which may fairly be set down to the engine itself, the solution is to be divided between the governor and the flywheel. Indeed, in those cases where the speed is to be constant at all loads, it is the flywheel which must first encounter the sudden change of load; no mere valve-governor, however sensitive, can do so satisfactorily. Where the speed has to vary slightly as the load varies, the case is different; the flywheel is then rather a hindrance than a help, but the governor is powerless unless aided by electrical regulation of some kind. It is mechanically impossible for any engine instantaneously to change from one speed to a considerably different one; so that,

Digitized by Google

in this case, the engine itself is powerless to prevent a blink in the lights, when a large instantaneous change takes place in the load. Fortunately, we do not, in our electric supply stations, expect the engines to meet sudden loads by sudden changes of speed. The flywheel, therefore, performs the useful duty of combating the sharpness or shock of the change in load. It tides over the difficulty during the brief interval which the valve-governor requires for its re-adjustment. On this account it is impossible to make the governor more sensitive than the flywheel, without introducing serious elements of instability, and causing the governor to hunt. As to the want of isochronism, to which our contemporary refers, inasmuch as it is not a matter of sudden change but of final equilibrium, electrical engineers are not likely to be worried by it; for, even if the governor is a little out of isochronism, it is very easy to compensate for it electrically.

There are few things better calculated to thoroughly arouse the unregenerate savage latent within us than the failure of any one of the much-vaunted mechanical contrivances of modern civilisation to come up to the expectations formed of it. An express train which can be overtaken by a hansom cab, a telegraphic despatch which can be beaten by a cyclist, a "constant" supply of electric energy which justifies its name only from being constantly found wanting, an alternating system which alternates between light and darkness during the busiest hours of a foggy day, are instances. This being so, it is not perhaps so surprising as it might at first sight appear to find that even the natives are unable any longer to put up with the so-called telegraphic service of Spain. The telegraph system of the Peninsula is reported to be in "a most deplorable condition"; the normal time required for a telegram to reach Barcelona from Madrid is said to be of the order of five hours, whilst a day or a day and a half are on occasion needed. Meanwhile, cyclists and pigeons are carrying all before them. It is dangerous to generalise from a single experiment, but the following trial of the efficacy of Spanish telegraphy may at any rate be taken as corroborative of the above. At two p.m. one day last autumn a message was started from Ronda on its weary way to Granada, about one hundred miles distant, and, so far as our informant is aware, it is still *en route*; at any rate, the telegram had certainly not reached its destination three days after its despatch. How it comes about that, with so little apparent capacity present anywhere, the retardation should attain such enormous dimensions is somewhat of a mystery.

Cable Interruption:

	Date of Interruption.
Zanzibar-Mombasa	September 4th.
Macao-Hong Kong	September 25th.

The Vienna Underground Electric Railway.—The concession for an underground electric railway across Vienna, referred to in our issue of July 20th, has been granted by the Minister of Commerce to the Austrian Landbank.

Durham College of Science.—At Newcastle-on-Tyne, on Tuesday, the south-east and south-west wings of the Durham College of Science were inaugurated by the Mayor. A sum of about £90,000 is needed to complete the buildings and to relieve the council of their liabilities.

Niagara.—According to some calculations made by Prof. J. W. Spencer, the human race has for 31,000 years been neglecting the dynamical possibilities of the Niagara falls, and will have only another meagre 5,000 years in which to make up for lost time.

Military Telephony.—The Austro-Hungarian financial statement contains a demand for £2,500 to be devoted to the purchase of 14 complete telephonic equipments to be used for enabling officers commanding army corps to communicate with those in charge of the train.

Institution of Civil Engineers.—We are requested to repeat that the rebuilding of the Institution of Civil Engineers will not affect the place of meeting, as such arrangements have been made as will allow of the theatre and reception rooms under it being retained for use during the approaching session.

Hotly Pursued.—In the last act of a melodrama which was recently produced at a New York theatre, the villain of the piece jumps through a window to escape from his pursuers and lands himself on the live wires of a high-pressure electric supply, where he is roasted to death. In this *fin-de-siècle* manner is virtue triumphant.

An Electric Ambulance.—According to the *Electrical Engineer* of New York, the City of St. Louis has adopted a plan of conveying patients from the Dispensary to the City Hospital by means of an electric car fitted up as an ambulance. It is intended to run the car to all parts of the city in response to ambulance calls, and an average speed of twelve miles an hour will be permitted.

New Books.—The Cambridge University Press will shortly bring out a volume on "Mechanics and Hydrostatics," by Mr. R. T. Glazebrook, and another on "Electricity and Magnetism," by the same author.——"The Electrician" Company will publish next week "Electric Lamps and Electric Lighting," by Dr. J. A. Fleming, and will shortly issue "Electric Motive Power," by Mr. A. T. Snell.

The Hermite Electrical Sanitation Process.—The Ipswich Town Council decided, at their meeting on Wednesday, to adopt the Hermite process. This decision was unanimous, and resulted from the exceedingly favourable report submitted by the Sewerage Committee on the trials which have been made on the main sewers of the town during the last three months. We understand the permanent plant is to be proceeded with as rapidly as possible.

A 7,000-Ampere Switch.—Probably the largest switch, as regards current-carrying power, which has yet been made is the one recently supplied to the Electric Traction Company of Philadelphia. The switch is constructed to operate 7,000 amperes at 500 volts, and is of the "Ajax" pattern. Except the carrier and the stand, the entire switch is built of commercially pure copper; it occupies a space of 14in. by 13in. on the switchboard.

Electric Shocks.—We have received from Mr. W. Langdon, the well-known Superintendent of the Telegraph Department of the Midland Railway Company, a copy of some instructions issued by him in relation to the avoidance of electric shocks, and to the treatment of those who are suffering from the effects of electric shocks. In such instances, as in drowning, time is everything, and a few simple, easily learnt, easily remembered rules very desirable.

Fatal Accident at Boston.—A double fatality through electricity occurred in Boston (Mass.) last week. While a man was employed cleaning an electric light on the top of a high pole he received a shock and was killed. His body was suspended from the wires for half an hour. When men were put to work to remove it one of them came in contact with it, and was thrown head foremost on the sidewalk, and died shortly afterwards.

Institution of Mechanical Engineers.—The next ordinary general meeting of this Institution will be held on Wednesday evening, October 24th, and Thursday evening, October 25th, at 25, Great George-street. The chair will be taken at half-past 7 p.m. on each evening by the President, Prof. Alexander B. W. Kennedy. The following Papers will be read and discussed, as

Digitized by Google

far as time permits:—"The Manufacture of Standard Screws for Machine-made Watches," by C. J. Hewitt, of Prescot; "Drilling Machines for Cylindrical Boiler Shells," by S. Dixon, of Manchester.

Military Telephony.—Passing to non-personal equipment, a novelty, says *The Times* correspondent, speaking of the recent French army manœuvres, was this year presented by the French infantry in the matter of telephone equipment. Each regiment is supplied with two portable telephone instruments, three kilomètres of wire carried on bobbins by men, a light bamboo ladder, and two forked poles. With this material communication can be rapidly established in billets between regimental and brigade headquarters, or from a fraction of the outposts to the rear.

Interurban Telephony.—The Hungarian Minister of Commerce is at present occupied with the elaboration of an extensive plan of interurban telephony, which will shortly be laid before the Hungarian Parliament for approval. Within three years it is hoped that all the large towns in Hungary will be placed in telephonic communication with one another, and with the capital. The first object of this scheme is, it is said, to facilitate interurban communication for administrative purposes, although, of course, it is the commercial community which will have to pay the piper, and will, it is presumed, reap the main benefit.

"Science Progress."—The October number of *Science Progress*, a monthly review of current scientific investigation, contains the first of a series of articles on "Continuous Current Dynamos," by Mr. C. C. Hawkins. The article is admirably and clearly written, and reviews the stages of the development of the dynamo, from the empirical stage in which the Drs. Hopkinson found it, through the generalised mathematical theory which these investigators gave it, to the present complete theory upon which its design and use are based. The writer attaches high but not undue importance to the influence which the publication, in 1886, of the researches of the Drs. Hopkinson exerted upon the progress and evolution of the dynamo; and the article is, in many respects, a tribute to the work of these two men.

Arc Lamp Carbons.—Some tests which have recently been made on the comparative life and efficiency of the "Union" carbon, and some American makes of arc lamp carbon, may be interesting to our readers. The carbons tested were uniformly $\frac{7}{16}$in. diameter, and they were all burned in the same lamp. The longest life attained with a positive cored carbon was 18 hr. 53 min., the horizontal candle-power being 159, and the consumption 361 watts; the shortest life was 9 hr. 14 min., with a positive solid carbon, the horizontal candle-power being 359, and the consumption 445 watts. The former of these was a "Union" carbon, the latter a Washington make. The shortest life of a "Union" carbon appeared to be about 12 hours, when the lamp was giving 316 horizontal candle-power, and absorbing 424 watts.

A Municipal Lighting Plant Investigation.—In its issue of September 5th, the *Electrical Engineer* of New York publishes an elaborate analysis by Mr. Horatio Foster, of the financial position of some 49 American municipal electric lighting plants, about which it may be said that they are mostly small and mainly street lighting plants. "In no respect," says our contemporary, "do these figures justify the statements that have been made as to the superior economy of municipal plants. On the contrary, the private lighting companies operate more cheaply, and when placed on a parity with the municipal plants as to taxation, &c., are able to supply a town with light as cheaply as it can supply itself. The conclusion might be stated even more strongly, but our readers can study the figures for themselves, and draw their own conclusions."

A Chimney Struck by Lightning.—We have received from a Russian correspondent an interesting photograph showing the curious effect of a lightning discharge upon an unprotected factory chimney. The chimney, which is about 180ft. high and a little over 6ft. diameter at the top, was finished on August 17th, and on the 19th of that same month it was struck by a lightning flash, which rent open the brickwork in a vertical line from top to bottom. The width of the gap was in some places as great as two feet; yet the chimney preserved its erect position and remained intact during the subsequent repairs. The photograph shows the lower portion of the rent filled in with new brickwork, and we understand that the structure is now in a perfectly stable condition. The chimney is at the sugar works of Count Branitski, in the province of Kiew.

The "Elektrotechnische Zeitschrift."—The issue of the *Elektrotechnische Zeitschrift* for the 27th ult. contains the farewell statement of Herr F. Uppenborn, who has occupied the editorial chair since the electrically Dark Ages—that is to say, for nearly 13 years—and who has been succeeded by Herren G. Kapp and J. H. West, the journal under their ægis becoming also the official organ of the Verband Deutscher Elektrotechniker. In the issue of October 4th the new editors make their editorial bow. The first number under the new management contains amongst other contributions a well-illustrated nine-column description of the electric lighting of Arundel Castle, six columns on the telegraph service of the United Kingdom, a description of the Duncan alternate-current meter, and a review of Mr. Oliver Heaviside's new book, "Electromagnetic Theory."

Electric Cars and Moving Houses by Trolley.—A novel and successful application of the trolley, says the *Electrical Engineer* of New York, was recently seen in Hoboken, N.J. A good-sized frame house was being moved, and *en route* to its final destination had to cross the electric railway tracks. As the wires, of course, had to be cut and traffic suspended during the passage of the building, it was desirable that this should occupy as little time as possible. A car was therefore put at the disposal of the movers, and when the house had been brought as near the track as possible tackle was rigged about blocks across the street and attached to the rear coupling. The wires were then cut and cleared away, and the car moved off, drawing the house quickly across the tracks and out of the way. The wires were reconnected and traffic was resumed, the whole operation occupying but a few minutes.

Alternate Currents and Fuses.—Some experiments, with a view to determine if an alternating current has any influence on the resistance and fusing point of fusible cut-outs, have recently been made by Prof. D. C. Jackson and Mr. Ochsner, and the results are embodied in the Paper in the *Transactions* of the American Institute of Electrical Engineers, Vol. XI., p. 455. Samples of a number of commercial fuses and wires of various metals were tested; but in no case was any evidence found that an alternating current has any direct effect on the resistance or the fusing temperature of the material. The influence of the alternating current was found to be always the same as that of an equal continuous current; except in so far as secondary actions, such as mechanical shaking, might arise from the alternations of current. The limit of time up to which results are true is 550 hours for the resistance tests, but the limit is not stated in the case of the fusing temperature tests.

Secondary Batteries.—In a Paper read before the American Institute of Electrical Engineers by Mr. W. W. Griscom, "On Some Storage Battery Phenomena," the author arrives at the following conclusions: 1. That the chemical reactions in a storage battery cell must be complex, in order to account for the curves of electromotive force, temperature, and internal resistance. 2. That the current and the electromotive force of the component plates of a cell, and of each part of each plate, are constantly fluctuating, in spite of the fact that no source of electricity can compare with a storage battery for steadiness and constancy. 3. That by reducing the normal output of a battery by about 30 or 40 per cent. the discharge can be mainly confined to one set of chemical reactions, thus prolonging the life of the battery. 4. That the negative and positive plates are apt to get out of step, therefore the battery should be given an occasional overcharge when necessary, but only when necessary to get them in line again.

Transforming Frequencies.—For the laboratory and for experimental purposes a method, by means of which an alternating current of any frequency may be obtained, is of obvious

Digitized by Google

value. Lieut. Patten, in an article in the *Electrical World* of New York, shows how this may be done. The method consists in turning an armature in a rotary field in a direction opposite to that in which the field rotates. If the two speeds are equal there will be a frequency of double the fundamental one, while with the armature at rest it merely acts as a transformer, and gives the fundamental frequency. By means of another combination, any desired frequency below the fundamental one may be obtained, even as low as a single period per second. We may note in this connection that a patent was recently granted in America to Mr. C. S. Bradley for a method of transforming frequencies of alternating currents, which consists in creating an alternating magnetic field and rotating in it a circuit so as to pass the poles at a fractional part of the rate of the alternating current itself. This seems to be somewhat similar to one of the methods described by Lieut. Patten.

High-Pressure Feeders at Worcester.—As we announced last week, the main feeders from the generating station at Powick to the high-pressure distributing sub-station at All Hallows are laid on the Brooks system of oil insulation, which system has proved itself so satisfactory at Chatham, Rochester, Keswick, and numerous other places where it has been in use for some few years. These feeders consist of three heavy wrought iron tubes, the metal having a minimum thickness of 0·25 of an inch, and an internal diameter of 2 inches. The conductors drawn into two of these tubes are made up of two 19/14 and two pilot wires laid up together into one cable, the remaining tube being left spare. Special joint and junction boxes are placed at various points along the line, from which branch connections may be taken as required. Midway along the line an oil pressure tower has been erected, allowing for expansion and contraction (due to variations in temperature) of the thick heavy, insulation oil. During the laying a very careful test was kept on the cable, and they were finally flashed with double the working pressure, namely 5,000 volts. The contract for the supply and laying of these feeders was given to Messrs. Johnson and Phillips, who are the sole makers of this system.

Operating Guns by Electricity.—The Ordnance Department of the United States Navy, says the *Army and Navy Journal*, has practically determined to operate the guns and turrets of some of its ships by means of electricity for the future. "It is not yet intended to actually displace steam by the new motive power; but to so place it that in case of accident it may be switched on, and thus prevent the gun being thrown out of action. It is a wise step to make electricity at first only accessory to steam; but that, on the whole, electric motors are a preferable means of working guns has been determined after a series of experiments, the stringency of which was intended to bring out weak points if such existed. The advantages of the system are considered to lie in the greater simplicity of electric conductors compared with steam pipes, both as regards the ease of carrying them round bulkheads, and the smaller surface exposed to injury, together with the facility with which they can be repaired. Chief of all advantages is considered the greater simplicity of manipulating the controlling switch as against steam valves. A single lever, according to the system devised by Capt. Samson, effects the operations of training and elevating."

"Punch" on the Galvanic Ring.—All persons afflicted with imaginary diseases are earnestly recommended by *Punch*, Vol. VIII., 1845, page 167, to try the galvanic ring. It signifies not whose ring out of the large variety advertised they may select, since the virtues of all are equal. These rings consist of a thin wire of zinc, soldered to a similar wire of copper; hence the quantity of galvanism they generate is next to nothing; certainly much less than that produced by a sixpence and a half-sovereign lying in contact in a gentleman's waistcoat pocket. Its exact amount it would be difficult to compute, as the galvanic fluid has no weight; but, giving a rough guess, we should say that it may be about the decillionth part of a suspicion. The tremendous effects on the system of this strong homœpathic amount of galvanism passing through the little finger may be conceived. But to quiet alarm, we may state that none whatever of this frightful torrent of galvanism developed by the ring passes through the finger at all. To be affected by galvanism, it is necessary that the part to be galvanised should lie between two opposite galvanic poles or extremities; now, as the finger is inside the ring, the galvanism is outside the finger. Thus, the finger is to the galvanic fluid as a person standing on the Isle of Dogs is to the fluid in the Thames. With what power an inappreciable force, ineffectually applied to the extremity of the body, must act in the cure of such a complaint as rheumatism is obvious. In all positive diseases the galvanic ring will afford a negative relief; and those who have nothing the matter with them may confidently depend on being cured by it.

Electric Motors in Workshops.—On the 9th inst. a visit was paid by the Society of Engineers to Messrs. Siemens Brothers and Co.'s works at Charlton. All the machinery in these shops is driven by electric motors. The plant at the electric generating station comprises three tubular boilers of gunboat type (two more in course of erection), each 18ft. long by 9ft. diameter, 400 I.H.P. each, 140lb. steam pressure. Steam is largely used for heating purposes, as well as for the engines. There are four engines. One Belliss compound vertical enclosed, 300 I.H.P., running at 350 revolutions per minute. Cylinders, 15in. and 23in. by 10in. stroke. Three Willans' compound condensing, 300 I.H.P. each, running at 350 revolutions per minute. Cylinders 14in. and 20in. by 9in. stroke. Four dynamos are coupled direct to the above engines, for 120 volts, 2,000 amperes. The distribution of the electrical energy is by means of underground lead-cased cables. Over the boilers are the condensers, consisting of 27 double-concentric cylinders; the steam passes through the annular space, while cooling water runs down inside and out. This water is used over and over again. There are in all 54 electric motors in the works, namely, 13 of 40 H.P. each, four of these in the rubber shop are directly connected by spur gear in the rolls; seven of 20 H.P. each; two of 15 H.P. each: these are directly coupled to a worm shaft driving the calendering rolls in the rubber shop, and are constructed to run at two different speeds; eight of 10 H.P. each, one of these is directly coupled to a cable machine, another works the lift in the rubber shop; 24 of various powers, from 10 H.P. to ½ H.P., mostly directly coupled to lathes and other machine tools.

Inductance and Capacity.—The neutralisation of the inductance of a line by means of a capacity, or *vice versa*, has been the subject of much mathematical writing, says the *Electrical World* of New York. What the average student of electrical phenomena wishes is first an idea of the mechanism of a phenomenon, as without this preliminary knowledge mathematical and graphical references to it will be likely to convey little information. For these the following may convey in a simple manner the idea of the respective action of a condenser and an inductance coil in series in an alternating circuit. Imagine the electromotive force of the circuit to be rising; the result on the one hand will be that the condenser will be unbalanced, and consequently will create a draught, so to speak, for enough current to again balance it; on the other hand, the increasing flow of current due to the increasing electromotive force will introduce into the inductance coil lines of force opposing the flow of the current, or, in other words, lines of force generating a current in the opposite direction to the main current, and in the direction of the draught of the condenser. If now, the condenser and inductance coil are so proportioned to each other that these two effects are equal, the result will be that the flow of current in the circuit will follow the simple form of Ohm's law, the factors in the impedance formula for inductance and capacity cancelling each other. The relative effects of inductance and capacity may also be illustrated roughly by an analogue from steam engineering. In the exhaust pipe of a marine engine there is often a throttle valve, automatically actuated and used to prevent the engine from racing in a rough sea. In this case the throttle corresponds to an inductance and the steam condenser to a capacity. By opening the throttle wider (decreasing the inductance) or increasing the vacuum in the condenser (increasing the capacity) the flow of steam is facilitated; or, by increasing the vacuum and throttling at the same time, one effect will nullify the other.

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(*Continued from page 660.*)

A bar cutter has been patented quite recently by Messrs. T. Heppell and Patterson, which embodies some novel features. One of the special points is the endless chain used to clear away the cuttings. This is shielded by a strong guard. The gearing consists of cast steel bevelled

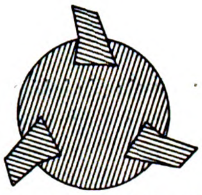

Fig. 121.—Section of Birtley Cutter Bar.

wheels and pinions. The machine is propelled by means of a steel rope which passes round a drum geared to the armature shaft by worm gearing, an eccentric, rod, pawl and ratchet. The design is very compact and appears to be capable of being worked into a less height than the type of bar cutter adopted by other makers; but this remains to be proved, for many alterations may be required before the machine gets

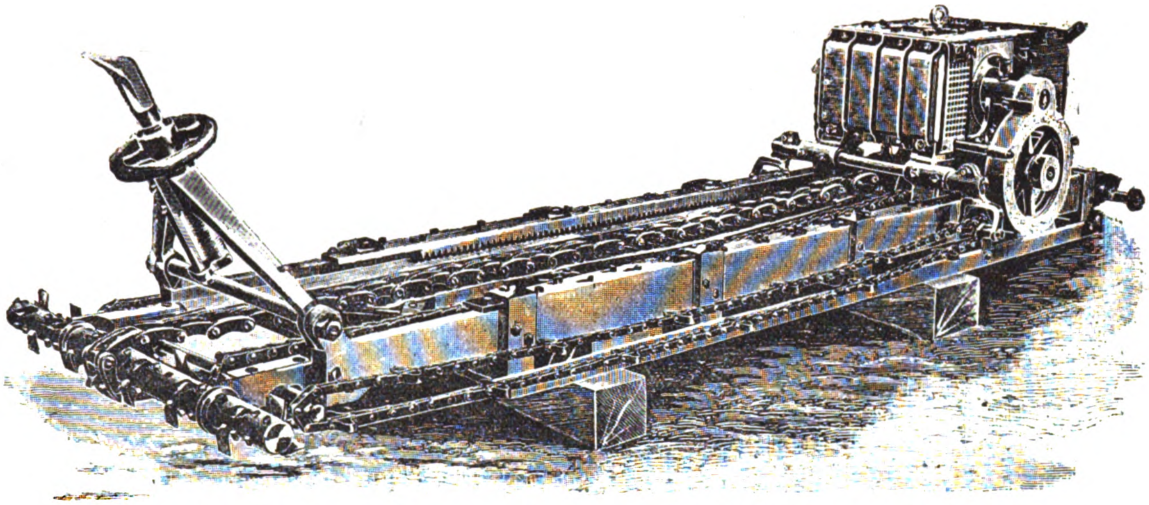

Fig. 122.—Jeffrey Electric Coal Cutter, showing cutter bar and jack for fixing the machine.

into regular work. At present the writer believes that one of these machines is at work in the Cannock Chase district. Mr. Heppell says that one at the Pilner Main Collieries is doing good work, cutting at the rate of about 20 yards per hour, 3ft. under. A sectional view of the cutter bar is shown in Fig. 121. It is arranged to swing about the centre of supports, which permits of the cutters being readily examined and also facilitates the moving of the machine about a coal pit. It has three dovetailed grooves cut along its length. The cutters have corresponding dovetails, and are distanced by suitable pieces of steel. The cutters can obviously be arranged spirally or otherwise, as may be required.

The Jeffrey bar cutter is of different construction from any machine of English origin, and was, no doubt, first designed to meet the conditions of the American coal seams. Special machines are built to suit the conditions obtaining in British mines. The details of construction are shown in Fig. 122.

It will be seen that the bar lies parallel to the coal face when in the cutting position. It is designed to hole as deep as 7ft. Deep undercutting is an especial advantage in pillar and stall working with an average roof. The machine consists of a bed-frame, occupying a space 3ft. wide by 7ft. 2in. long, built up of two steel channel bars firmly braced, the top plates on each forming racks with the teeth downwards. Mounted upon and engaging with this bed-frame is the sliding frame, consisting mainly of two steel bars, well braced, upon which are mounted at the rear end an electric motor. Upon the front end of this sliding frame is mounted the cutter bar, held firmly by two solid steel shoes with brass bearings. The cutter bar receives motion through an endless steel or bronze chain from the driving shaft, and as it revolves is fed forward by means of straight-cut gear and a worm and wheel. The bar is usually 36in. wide. In America the seams are generally much thicker than those here, and the roofs are sufficiently good to enable the face to be kept open for the distance necessary with a 6ft. or 7ft. holing, and pillar and stall working is chiefly practised. But in England the conditions of long-wall working do not, as a rule, permit of such deep undercutting, and from 4ft. to 5ft. is, as a rule, the deepest cut advisable. At the Cannock and Rugeley Collieries, where two of the Jeffrey machines are at work, one holes 4ft. and the other 7ft.

The electric motor occupies a space of about 20 inches square. It is designed to absorb a maximum of 15 E.H.P., and in some veins of coal does not require more than 7·5 H.P. The American standard pressure is 220 volts, but this can be altered to suit circumstances. The armature is designed to run at 1,000 revolutions per minute, and the cutter bar at 200. The momentum of the moving parts is such that the machine overcomes ordinary obstacles without difficulty, and since the motor is not coupled rigidly to the bar the vibrations are not transmitted to it, and the machine runs steadily and comparatively quietly. Two men are required to work the machine, one at the switch at the back and the other as helper to clear the debris and to assist in shifting. The machine is taken from stall to stall on a special truck. When at work it is slid on to two boards or bars of iron in front of the coal, and fastened firmly by means of the front and rear jacks against the face and roof of the coal, which is thus supported to some extent during the under-cutting. When the full depth of the cut is reached the feed is thrown off, and the cutter bar is returned to the starting position by means of reversing gear. The machine is then moved sideways for a distance equal to the length of the cutter bar, and another cut is made in the same manner. Each cut is made in ordinary working in from three to six minutes. The output depends to a great extent upon the skill of the men in moving and jacking the machine, and also upon the hardness of the coal, and whether the cut is made in coal or "dirt." In some seams these machines are said to cut from 40 to 66 linear yards of face to a depth of 6ft. in a shift of 10 hours. Since the depth of the undercut is roughly twice as great as that usually made with a bar machine of the Goolden-Atkinson type, this is equal to a length of face of from 80 to 130 yards, in comparison with the performance of the latter. Assuming these figures to be correct, it would appear that although the Jeffrey machine has to be shifted after every cut, yet it can cut a

* All rights of reproduction reserved.

Digitized by Google

greater area of coal than the Goolden-Atkinson machine in the same time.

In comparing the two types stress must be laid on the relative suitability for different kinds of work. The Goolden-Atkinson machine requires a space between the face and the props at the goaf of not more than four feet at the outside, whereas the Jeffrey machine cannot be worked in a smaller space than six feet; but with the latter the depth of undercut may be nearly double that with the formes, though, of course, the total length of roof unsupported is then nearly twice as great. It is, therefore, obvious that the side cutter bar can be used in places where the front cutter bar cannot possibly be. It must be remembered also that the Jeffrey coal cutter makes a capital heading machine, while the side cutter cannot be used for this purpose. The two machines are not, therefore, rivals for the same work in all cases. They cost in the first instance about the same. The motors are of the same rated capacity, and the actual power required in practice appears to be about the same. Hence there does not seem to be much to choose between them as regards the question of cost, but it is rather a matter of suitability for any particular case.

Mr. Williamson, of Cannock and Rugeley Collieries, who is using one of these machines with a 36in. bar, holing 4ft. in a 5ft. seam, says that the output of round coal is increased 15 per cent. That is to say, hand cutting makes 75 per cent. of round coal and the Jeffrey cutter 90. And that one machine, working single shifts, has increased the output by at least 60 tons per day.

A number of patents have been taken out for machines with rotary wheels. In a few the wheels have been designed to cut vertically, or even at any angle, but in the majority the aim has been simply to make a horizontal cut as near the bottom as possible. The depth of the undercut determines the diameter of the wheel, and is limited in practice to from 39 to 55 inches, the latter being found to be as deep a cut as is desirable. If this depth be exceeded there is a strong probability of the coal shearing at the back, and fouling the wheel before it is clear of the cut, and if the cut be shallower the coal will not break readily by its own weight, but requires wedging down.

Passing by the early inventors of these machines and coming to modern history, the name of Messrs. Gillot and Copley stands in the front rank; but from some cause, which is not very apparent, this firm has not shown a disposition to apply electric motors to their machines, preferring to continue the use of compressed air.

The Yorkshire Engine Company have also built some excellent machines of this type embodying several improvements on those of the former firm. They also have confined themselves to compressed air, although they have built to order a few electrically driven machines. An illustration of one of their machines is given in Fig. 123, in order to show the general requirements of this type of plant, and also because the writer has found from actual experience that they do excellent work.

Fig. 124 is an enlarged view of the cutter wheel, showing the method of supporting it in bearings. The design is arranged to hole at a few inches above the rail tops. Owing to the success which this class of coal cutter has obtained when driven by compressed air no radical change has been attempted by inventors when applying electricity. They have accepted the main principle and have simply changed the motive power.

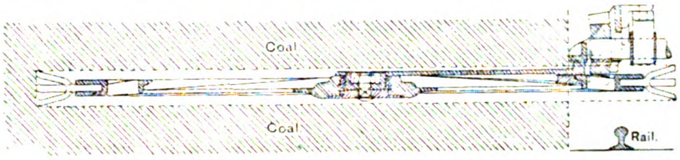

Fig. 124.—Cutter Wheel: Yorkshire Engine Company.

On referring to Fig. 124 it will be seen that the side wheel is fitted with two kinds of cutters. Every alternate one has Y-shaped teeth, while the remainder are straight. The function of the latter is to tear out the centre of the cut, while the former clears it out to the desired width, usually about 3in. In air-driven machines the speed of the wheel varies from 15 to 30 revolutions per minute, according to the kind of dirt and its resistance. This speed is found to be too slow for the electric motor, since the reducing gear is costly and cumbersome. Therefore all who have tried to apply electricity have endeavoured to raise the cutter wheel speed as much as possible. This has necessitated strengthening the machine as a whole, and has increased the dead weight from about 25cwt. to about 35cwt. The increased speed has caused no trouble in working however. In fact, the momentum of the moving parts is so great that obstacles which caused serious shocks at the slower speed are scarcely felt at the higher speed of from 70 to 100 revolutions per minute. And the increased weight tends to prevent derailment.

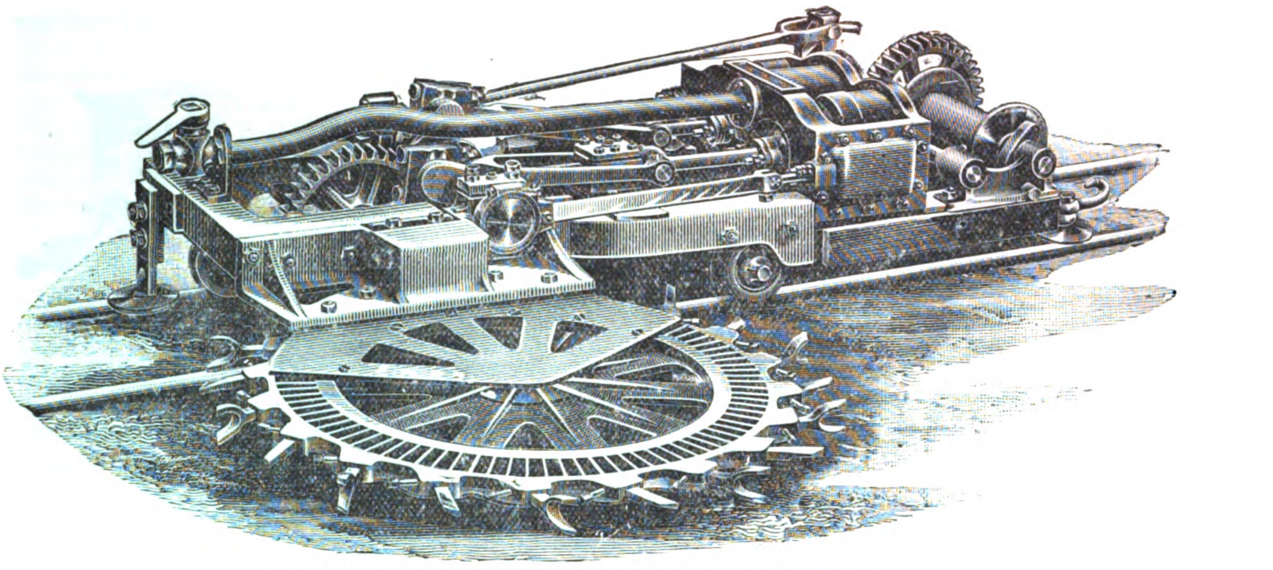

Fig. 123.—Yorkshire Engine Company's Side Wheel Coal Cutter.

(To be concluded.)

THE CHEMICAL THEORY OF ACCUMULATORS.—IV.

BY E. J. WADE.

The only theory that now remains to be examined thermochemically is the generally accepted one of the direct formation of lead sulphate at both electrodes by the abstraction of two molecules of sulphuric acid, which are replaced by two molecules of water. The chemical equation for the ultimate products of this reaction is

$$PbO^2 + 2H^2SO^4 + Pb = PbSO^4 + 2H^2O + PbSO^4.$$

Digitized by Google

It is a little difficult to express these changes in an electrolytic equation, but the following, perhaps, illustrates what apparently occurs

$$\begin{array}{l|l|l} SO^4H^2 & & \\ PbOO & H^2SO^4 & Pb \end{array} = \begin{array}{l|l|l|l} & SO^4 & H^2 & \\ Pb & O & OH^2 & SO^4Pb. \end{array}$$

It will be noticed that the second molecule of sulphuric acid (placed above PbO^2) does not appear to undergo ordinary electrolytic decomposition, but combines what is usually termed a *secondary* reaction, and one which is so often supposed not to contribute anything to the electrical activity of the cell.

The usual form of the thermo-chemical equation for the above reactions is as follows,

$$\left.\begin{array}{l} [2Pb,SO^4] + [2H^2,O] - [2H^2,SO^4,Aq] - [Pb,O^2] \\ 225940 + 136720 - 215060 - 62300 \end{array}\right\} \begin{array}{l} = 85300 \\ = 1{\cdot}855 \text{ volts.} \end{array}$$

This figure, while considerably higher than those obtained from any of the previous equations, and approaching nearer to the observed E.M.F., yet falls short of it by a very appreciable amount, the discrepancy being quite sufficient to suggest that it does not fully represent what actually occurs. It will be noticed, however, that it is assumed that the acid is diluted with an infinite or very large quantity of water; practically speaking, that a very dilute solution of acid is employed. Now Messrs. Armstrong and Robertson and others have suggested that the real electrolyte is either pure sulphuric acid or one of its simplest hydrates, and that the energy absorbed in abstracting this from the solution during discharge is supplied by the cooling of the cell which then takes place. If this is so, it obviously must not be taken into account when calculating the E.M.F., which will be entirely independent of the degree of dilution of the acid.

On this assumption the thermo-chemical equation for pure sulphuric acid is :—

$$\left.\begin{array}{l} [2Pb,SO^4] + [2H^2,O] - [2H^2,SO^4] - [Pb,O^2] \\ 225940 + 136720 - 179360 - 62300 \end{array}\right\} \begin{array}{l} = 121000 \\ = 2{\cdot}63 \text{ volts.} \end{array}$$

This result is of course simply that given by the previous equation, plus the energy liberated by the complete hydration of two molecules of sulphuric acid (2×35700 calories = 0·775 volt), and is about twice as much too high as the preceding value was too low; which seems to indicate that the explanation of the discrepancy does not lie in that direction. Besides this, the researches of Messrs. Gladstone and Hibbert have proved conclusively that, in some way or another, the of E.M.F. of a cell does depend on the strength of acid employed. Their observations included measurements of the E.M.F. in all strengths of acid, from water containing the merest trace up to the very strongest acid that could be procured, and the mean result of the whole of them is embodied in curve *c*, Fig. 1. Most of their values for the higher percentages of acid were obtained with only the peroxide plate in the strong acid on account of the excessive local action that took place at the spongy lead plate under similar conditions, and these figures have therefore had to be corrected for both plates in the same strength of acid from the data they themselves furnish the E.M.F. between two plates of plain lead in different of strengths of acid.

Only the middle portion of this curve can be considered to correspond with the normal reactions represented in the thermo-chemical equation. The rapid fall of E.M.F. which commences with about a 10 per cent. solution, and becomes very marked for strengths below 5 per cent., is due to the formation of basic sulphate and oxide which Messrs. Gladstone and Tribe long ago showed to take place in weak acid. The turning over or flattening of the curve for the highest strengths of acid does not appear to have been specially noticed; but it is, no doubt, due to the local action, which takes place with increasing rapidity in 40 to 50 per cent. solutions (Sp. Gr. 1·300 to 1·400) and upwards, and it might, in fact, have been predicted by *a priori* reasoning from the results of experiments by various investigators on the effects of local action on the E.M.F. of primary cells.

To ascertain how far this curve agrees with the calculated E.M.F. for various strengths of acid, intermediate values must be interpolated between the two extreme values already obtained for pure acid and for very dilute acid by substituting successively the heat formation of $[H^2,SO^4,H^2O]$ $[H^2,SO^4,2H^2O]$, $[H^2,SO^4,5H^2O]$, and so on in the thermo-chemical equation in place of $[H^2,SO^4]$, and the resultant curve is given in curve *a*, Fig. 1. On comparing the two curves A and C it will be observed that, as Messrs. Gladstone and Hibbert have already pointed out, they only coincide at two places—namely, for about 7 per cent. acid and for 100 per cent. or pure acid—and that for all other strengths the observed are considerable higher than the calculated figures. Now both these points of coincidence occur at parts of the curve of observed values where, as has been mentioned above, it corresponds to abnormal reactions whose resultant E.M.F. is lower than that normally to be expected, and it suggests the probability, therefore, that the agreement is only an accidental one and that—except for very weak acid, where the reason for the rapid fall of E.M.F. is known—a discrepancy still remains to be accounted for throughout its length, due perhaps to some portion of the reactions not having been properly or fully stated in working out the thermo-chemical equation.

A further and closer examination, however, of the changes occurring in the electrolyte shows that a reaction does exist which up to the present appears to have been overlooked. Full allowance has been made for the energy required to separate two molecules of acid from the water with which it is diluted, but no account has been taken of the energy due to the further dilution of the remaining acid by this liberated

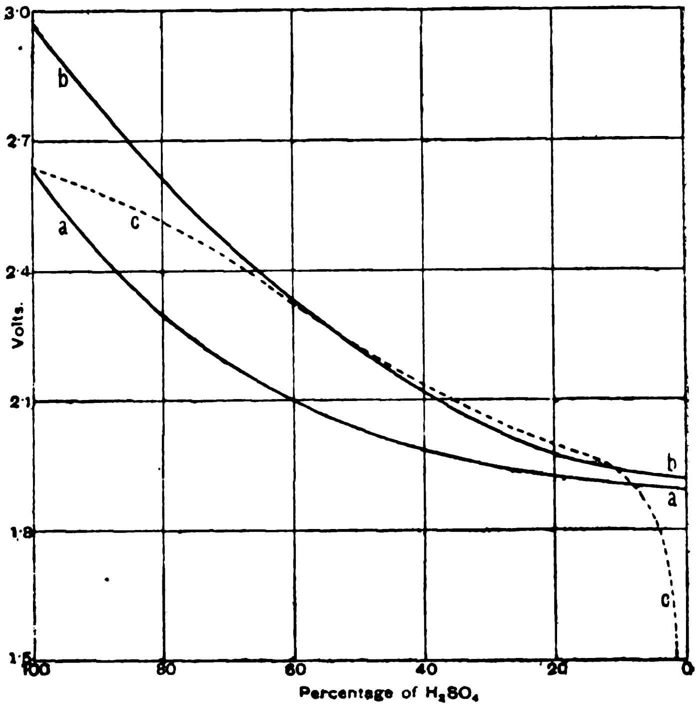

Fig. 1.

water together with the two molecules of water which replace the acid that has been used up. As an example of the difference made by this correction and the way it is applied, the case may be considered of a solution whose strength is represented by the formula $H^2SO^4,19H^2O$, corresponding to 22·3 per cent. of acid by weight or a density of about 1·163. The ordinary thermo-chemical equation, without taking this extra reaction into account, is :—

$$\left.\begin{array}{l} [2Pb,SO^4] + [2H^2,O] - [2H^2,SO^4,19H^2O] - [Pb,O^2] \\ 225940 + 136720 - 211870 - 62300 \end{array}\right\} \begin{array}{l} = 88490 = \\ 1{\cdot}923 \text{ volts.} \end{array}$$

Now the term to be added for the heat generated by the further dilution of the acid remaining is

$$+ [x(H^2SO^4 19H^2O), 2\ (19H^2O + H^2O)] = 3520 = {\cdot}077 \text{ volt},$$

and 1·923 volts + 0·077 volts = 2·0 volts.

x may stand for any quantity or number of molecules of dilute acid so long as it is sufficiently large that the addition of the extra water—in this case 40 molecules—does not sensibly alter its degree of dilution.

If the corresponding correction is made for the extreme case of perfectly pure acid it will at once be apparent that the only water here liberated are the two molecules

Digitized by Google

that replace the decomposed acid, and these combined with the remainder to such good effect that about 20,000 calories are liberated, equivalent to an additional ·435 volt. For the other extreme of a very weak solution, the acid is already so fully diluted that hardly any more heat can be generated whatever further quantity of water is added, and consequently the correction becomes comparatively small; but at the point where the E.M.F. drops off sharply—that is, about a six per cent. solution—it is still sufficiently large to be worth considering. Curve *b*, Fig. 1, gives the calculated E.M.F. *with the above correction* for all strengths of solution, and it will be observed that it practically coincides with the one giving the E.M.F. obtained by actual measurement, for solutions containing from 10 to 65 per cent. of acid, or thereabouts, corresponding to specific gravities from 1·070 to 1·570, which is a far wider range than is ever used in practical cells. Above 65 per cent. the curve of observed E.M.F.'s commences to fall away from the other, and continues to do so right up to 100 per cent., which is exactly what might be expected, and the reason for which has been already explained.

It may now fairly be claimed that the double sulphating theory of discharge does account for the E.M.F. of lead storage cells strictly in accordance with Thomson's law, while none of the others do so even approximately; and, from a thermo-chemical point of view, therefore, its case may be considered as proved.

Although it might not at first sight appear probable that such a minor matter as that of the rate of dilution of the acid in a cell during discharge could have any practical bearing on the design of accumulators, yet it does suggest some considerations regarding the amount of acid required and its best distribution, which are of considerable interest. The results to which they lead have long ago been more or less completely recognised as the outcome of actual experience, without a very clear comprehension of the underlying reason, and they will well bear a little further emphasising and explanation. It has already been mentioned that in the early days of lead accumulators, the only function supposed to be served by the sulphuric acid was to render the electrolyte conductive, and that its presence in large quantities was considered to be actually injurious. But as soon as it was admitted that sulphating was one of the normal processes of discharge, it followed, as a necessary corollary, that at least the theoretical amount requisite for this purpose must be supplied and a little over, to prevent the solution from being reduced to pure water by its complete abstraction. Experience, however, quickly demonstrated that a cell worked far better when a large excess of acid was present so as to prevent the specific gravity from falling too low or varying between too wide limits, and a proportion of from three to five times the necessary amount was finally adopted and has remained the general practice ever since.

Next it was found that not only must the quantity of acid in the solution be large, but it must also have a free access to the surface of the electrodes; and experiment showed that, within certain limits, cells worked more efficiently the further the plates were apart, in spite of the fact that the losses due to internal resistance must be proportionately increased. More recently, the researches of Messrs. Gladstone and Hibbert into the variations of E.M.F. with strength of acid, and of Messrs. Duncan and Wiegand into the rates of diffusion from the active material into the surrounding liquid, have incidentally confirmed the necessity of providing for a rapid diffusion and free supply, not only throughout the main body of the electrolyte at the surface of the electrodes, but also with regard to the whole mass of the active material and the acid contained within its pores. Now, although unconsciously, the tendency and ultimate object of every one of these modifications is to enable the utmost energy to be obtained from the recombination of the liberated water, with the conversion of the largest possible percentage of it into electrical work, and the smallest possible percentage into heat. That an insufficient supply of acid causes a reduction in the practical capacity of a cell, and that a poor circulation throughout the bulk of the electrolyte, or an impeded diffusion within the pores of the active material, causes both this and an actual loss of efficiency as well may be proved by considering the following hypothetical case.

Suppose a set of positive and negative plates are run down in a cell holding very little more acid than is theoretically sufficient for their discharge, but standing in another vessel which contains a much larger quantity of acid of the same specific gravity. The two liquids are completely separated by the inner cell; but when required it can be removed, leaving them in free communication. On the completion of the discharge a certain amount of energy will have been given out in watt hours, and the electrolyte reduced to an extremely weak solution of acid. The inner vessel is next removed and the two solutions allowed to mix. The dilution of the stronger by the weaker acid causes the liberation of a definite quantity of heat, which could be measured by suitable apparatus, and its electrical equivalent in watt hours calculated.

Now, if the dividing cell had been removed *before* the discharge began, and the plates run down in the larger quantity of acid, it is evident that, the final conditions being the same, the total amount of energy liberated must be equal to that given out electrically when the discharge took place in the smaller vessel, plus the heat generated in mixing the liquids; but *the whole of it will now appear as electrical energy*, the difference being shown by the higher and more constant E.M.F. maintained owing to the strength of acid for corresponding periods of the two discharges always being greater in the latter than in the former case.

Practically, then, an insufficient supply of acid means a rapid fall of voltage during discharge, and indirectly, therefore, a smaller output in ampere hours, because the maximum permissible drop of E.M.F. will be reached at an earlier stage.

A consideration, however, of what takes place during recharging will show that the *efficiency* is not affected or reduced. If the cell is charged in the larger quantity of acid, the work that must be done upon it will exceed that necessary if charged in the smaller cell by the amount that was liberated on mixing the two solutions; but this is just the amount by which the energy of the one exceeded that of the other during discharge, and, therefore, the ratio in watt hours of charge to discharge—that is to say, the efficiency—will be the same in both instances. As on discharge so on charge, the strength of acid for corresponding periods will always be greater in the former than in the latter case, so that the back E.M.F. and the charging E.M.F. required to overcome it will also be larger.

The conditions that exist in a cell plentifully supplied with acid; but in which, owing to a poor disposition of the parts or insufficient porosity of the active material, the diffusion is more or less impeded, may be represented in an exaggerated form by supposing that the containing vessel for the smaller quantity of acid is of a porous nature and allows a certain amount of diffusion to take place between the two liquids. Assuming that the rate of diffusion is very slow, the discharge will reduce the strength of the solution in the inner vessel to practically the same degree as before, and the same amount of energy will be given out electrically; while, by leaving them until the solutions in both vessels are equalised, the same amount of heat will be liberated, only more slowly. On proceeding to charge, however, the conditions are different. The strength of acid in the inner is now the same as that in the outer cell to begin with, and, moreover, it concentrates rapidly, so that by the time the charging is completed it is considerably the stronger of the two. On leaving at rest equilibrium will again be restored by diffusion, and a further quantity of heat generated, this time at the expense of the solution in the smaller vessel, which proves that more work has been done than would have been necessary if there had been free communication between one and the other. Imperfect diffusion, therefore, means a loss of electrical energy both during charge and discharge by the direct production of heat, and, consequently, a reduced efficiency, which makes itself apparent in an unduly low E.M.F. when discharging and an unduly high back E.M.F. when charging. No account is, of course, taken in the above examples of variations of internal resistance with changes in the strength of acid, as this would only complicate matters; also, the rate of charge and discharge is assumed to always be the same. It would approximate more nearly to the conditions that actually

Digitized by Google

exist in practice if diffusion through the porous pot were supposed to be constantly taking place during charge and discharge, although not with sufficient rapidity to maintain equilibrium, but it would not then afford such a good illustration from a theoretical point of view.

Curve *b*, Fig. 1, was calculated on the extreme assumption that the quantity of electrolyte employed is so large, and the rate of equalisation of strength by diffusion so rapid, that no sensible weakening is produced during discharge, either in the bulk of free liquid or locally in the portions directly surrounding the active material; and in practice these conditions are very nearly attained in all well-designed cells. The total fall of E.M.F., due to weakening of the acid as a whole, is only about ·05 volt from beginning to end of discharge, and the further loss through imperfect diffusion is not much for reasonable rates of output. The latter loss, however, only appears as a polarisation effect, and must be measured accordingly—that is to say, it is not present on open circuit, and is dependent on the rate of working. If a series of curves, showing the variation of E.M.F. with strength of acid, were constructed on the assumption of various limited quantities of electrolyte, they would all be found to lie below curve *b*, the smaller the quantity the less being the E.M.F. for every given strength and the lower, therefore, the corresponding curve, but none of them would fall as low as curve *a*.

(To be continued.)

THE PHOTOMETRY OF DIFFUSED REFLECTION.*

BY E. LOMMEL.

In a previous Paper "On Fluorescence" I have shown, under the heading "The Principles of Photometry,"† that in theoretical photometry it is not the surface elements of the luminous surface, but the volume elements of the luminous body which must be regarded as emitting light. Accordingly, the following three propositions were taken as a basis for the theoretical treatment of photometric problems :—

1. The quantity of light radiated from one volume element to another is inversely proportional to the square of their distance.

2. The quantity of light emitted from a volume element, and incident upon a surface element, is proportional to the cosine of the angle of incidence.

3. The light radiated by a volume element is enfeebled on its way through the radiating body according to the law of absorption.

Lambert's law of the cosine of the angle of emission was thus eliminated from the set of photometric principles, and its place was taken by the present proposition 3. The cosine law was now obtained as a consequence of the above principles, but only for opaque glowing bodies ; for self-luminous bodies transmitting light, such as flames, the cosine law does not hold.

In the work referred to, the behaviour of none but self-luminous (incandescent and fluorescent) bodies was taken into account, whereas the much more difficult problem of bodies glowing with borrowed light by diffused reflection was left untouched.

For diffusively reflecting bodies also the cosine law had, since Lambert, been taken as determining the intensity of light reflected by them. This assumption could, however, neither be based upon theory, nor did it appear to correspond with the facts of observation. This state of things has recently been emphasised by Seeliger, with special reference to the photometry of the planets. He showed, by a series of observations, that an experimental corroboration of Lambert's law for diffusing bodies cannot be thought of. *Apropos* of these works of Seeliger, I have resumed the work already begun in 1880, dealing with the task of deducing the behaviour of diffusively reflecting bodies from the above-stated principles of photometry.

1. If through the surface $d\,\infty$ of the volume element $d\,\infty\;d\rho = d\,v$ of an illuminated diffusing body, the amount of light $d\,\infty$ (*i.e.*, unit light per unit of area) penetrates perpendicularly, let $l\,d\,\infty\,d\,\rho$ be the amount of light diffused in all directions by the volume element. The quantity l we may call the *diffusive power* of the body. This is independent of the colour of the incident light, and only depends upon the degree of dulness, pulverisation, disintegration, sponginess, cracked structure, &c., of the diffusing body ; for a perfectly clear, limpid body the diffusive power l is zero.

2. Since the beam of light of intensity $d\,\infty$, in passing through the distance $d\rho$, loses the amount of light $l\,d\,\infty\,d\,\rho$ diffused in all directions, it is enfeebled by diffusion according to the same law as holds good in the case of absorption.

* Abstract from *Wied. Ann.*, Vol. XXXVI., p. 473, 1889.
† *Wied. Ann.*, Vol. X., pp. 449 and 631, 1880.

3. At the same time it is enfeebled by absorption proper, both in passing through the diffusing particles themselves, and through the transparent medium in the space between them. By this absorption it loses the further quantity

$$k\,d\,\infty\,d\,\rho,$$

where the absorptive power k is a function of the wave length, since particles and medium may be "coloured."

4. The supposition hitherto made, that the volume element is a rectangular prism with its edges parallel to the direction of the incident beam, is not at all necessary. For, whatever may be the shape of the volume element, it may be supposed to be subdivided in a direction parallel to the rays into narrow right prisms, each of which affects the incident light in the manner specified. By a volume element of any shape, therefore, the quantities of light $k\,d\,v$ and $l\,d\,v$ are abstracted, by absorption and diffusion respectively, from a beam having unit quantity of light per unit of sectional area.

5. The quantity of light $l\,d\,v$ is radiated in all directions by the volume element. If we assume that the radiation takes place equally in all directions, then the surface 4π of a sphere described with unit radius about the volume element is uniformly illuminated by the quantity of light $l\,d\,v$. The quantity of light, therefore, which the element $d\,v$ radiates in any direction per unit of area of this sphere is

$$\frac{l}{4\pi}\,d\,v.$$

. . . . . . For absolutely white bodies (where R = 0), the amount of light radiated by a surface element $d\,\infty$ in all directions, when illuminated by parallel rays at an angle of incidence i is $a\,d\,\infty\cos i$, where a is the intensity of the incident light. The amount of light radiated by a body equally illuminated from all directions in a direction at an angle ϵ to the normal is $a\,d\,\infty\cos\epsilon$. We therefore obtain the following propositions :—

If an absolutely white body is illuminated by parallel rays from any direction, the amount of light sent out in all directions from its surface (its illuminating power) is proportional to the cosine of the angle of incidence.

If the surface of an absolutely white body is equally illuminated from all directions, the quantity of light radiated by it in any given direction is proportional to the cosine of the angle of emergence.

These propositions, enunciated for absolutely white bodies, also hold in coloured bodies, for those colours whose absorption may be taken as indefinitely feeble.

But these two propositions show in what sense, and with what reservations, the cosine law for the angles of incidence and emergence respectively may be taken as valid according to our theory. . . . The intensity of light L radiated in a direction ϵ, by an opaque diffusing body, when the light is incident vertically, is given by the formula—

$$\frac{4\pi}{a\,d\,\infty}\,L = \frac{l}{2\,(k+l)}\,(P+\mu\,Q),$$

$$\text{where } P = \frac{2\cos\epsilon}{\cos\epsilon+1}, \text{ and } Q = P\,(\log 2 + \cos\epsilon\,\log\frac{1+\cos\epsilon}{\cos\epsilon}).$$

[μ is a constant depending upon the physical constitution of the body.]

. . . Of the substances investigated, marble alone approximately follows the cosine law. According to our theory it would only hold in the case of illumination from all directions for a body approaching absolute white.

The numbers for paper and cardboard do, indeed, approach the new law more closely than the cosine law ; but we cannot speak of even an approximate correspondence. But since these substances are translucent, the formula found for perfectly opaque plates cannot be applied to them ; we should have to use the formula applicable to any given thickness of plate. But this would give for a thin sheet the light radiated as being independent of the angles of incidence and emergence. An increase of this amount of light with increasing angle of emergence up to a maximum, as found by observation, cannot be explained on the basis of the new law of emergence, any more than on that of the cosine law.

That the angles of incidence and emergence should be interchangeable, as demanded by Lambert's law as well as the new law, is also contradicted by the numbers obtained for paper and cardboard.

On the other hand, the values found for porcelain agree pretty closely with those calculated by the new law, while they diverge considerably from the cosine law. The "albedo" upon which the calculation was based was 0·4, which Lambert takes as the approximate value for white bodies in general. While the divergences from the cosine law amount to 31 per cent., they do not exceed 4 per cent. in the case of the new law.

In the preceding I have also indicated the method for the theoretical treatment of the diffused light passing through a translucent dull body. A closer investigation of this question is reserved for a future communication.

NOW READY.

Volume XXXII. of "THE ELECTRICIAN," price 12/6; post free, 13/6 abroad, carriage extra.

Cases for binding Volume XXXII., price 2/0, post free, 2/3.

The Publisher is able to supply a set of the Volumes of "THE ELECTRICIAN" complete except for three Nos. Price on application.

STEEL-PLATE PORTRAITS

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field; Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; and Dr. Heinrich Hertz, have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar of Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.).

AMERICAN NOTES.

If funds do not permit or if inclination does not lead the average English electrical engineer to betake himself from time to time across the Atlantic to see for himself all the engineering curiosities that the restless ingenuity of the Americans has prepared for him, the deficiencies of his education in this direction appear likely to be made good in some degree by the disinterested zeal of his more fortunate brethren. Hardly a year now passes without the members of the Institution of Electrical Engineers being enlightened by the American Notes of a brother member; a few years ago it was Mr. ADDENBROOKE, last spring it was Mr. PREECE, this autumn it is Mr. H. D. WILKINSON. The practice is one to be encouraged. A nation which considers that it has nothing to learn is in a parlous state; the bourne to which such self-sufficiency inevitably leads is just now being for the *n*th time made plain by the spectacle presented by the best known exponent of the art of celestial self-satisfaction.

At the same time it is somewhat to be regretted—not, of course, so far as the lucky individuals themselves are concerned—that almost all those who return from a tour in the States come back infected with the optimism, cheery nonchalance, and fondness for "sonorosities," which distinguish the Anglo-Saxons of America from those of Great Britain. Thus, in January last we were solemnly assured that "nothing grander in design or more beautiful in execution has ever been seen in this world," than Rome in the days of ANTONINES, no not exactly, "than the group of buildings situated in Jackson

Digitized by Google

Park, Chicago, and called the 'World's Fair,'" although the world for some reason failed to go there. Nothing but the exuberance of expression begotten of ten weeks' residence in the States could have led to such an entertaining exaggeration. The phlegmatic, critical Briton becomes, to all intents and purposes, a sort of inverted CÆSAR as soon as he sets foot in America; he goes, he sees, and is conquered. It is related of EMERSON, the confirmed optimist, that he was taken by CARLYLE, the confirmed pessimist, to see all the choicest horrors of the metropolis; but, notwithstanding, continued of the same cheerful opinion still. In much the same way, the author of "Notes on Electric Tramways in the United States and Canada" appears to have been taken in hand by his American friends, and to have found everything good. Cars "weighted out of shape and scraping the ground," rails "projecting above the road-bed one or two inches," tramcar lamps brilliantly lighted up by earth leakage, fragments of a flywheel being taken out "through an opening in the station wall," do not distress the translated Briton in the slightest, so long as the end is attained. At home no self-respecting Briton would allow himself to be baulked of a good grumble, if he were taken anywhere in third-class style at first-class fare, by the retort that he had "got there all the same," although in St. Louis or Chicago, apparently, this irrelevancy would completely silence him.

Stay-at-home electrical engineers, however, cannot afford more than other folk to look a gift horse in the mouth, and, instead of deploring this tendency to look at American phenomena through American glasses, they would do well to regard it as an outward and visible sign that a visit to America has in very truth been made. Too many who cross the Atlantic come back with their lips sealed by this or that consideration, or biassed by this or that interest, and apart from its value as a means of promoting discussion, Mr. WILKINSON's paper, which we commence to print in this issue in order that its existence may be brought to the timely notice of those desirous of taking part in the forthcoming debate at the Institution, is a useful index of the impression left by a careful inspection of transatlantic methods of electric tramway working. To paraphrase a remark of the author with regard to electrolytic corrosion in Boston, we may say in regard to electric traction men in the States generally: They have purchased experience at heavy cost, which should benefit us when our turn comes. To that end the author's emphasis of the great importance of rail-bonds of adequate cross section, his toleration of the double-trolley method of working, his favourable opinion of the Love slotted-conduit as judged by its performance at Chicago and Washington, his statement as to the revenue derived by tramway companies from current supplied off the 500-volt circuit to small motors, merit the attention and criticism of those engaged in the praiseworthy task of converting "the Britisher," and adapting the electric car to suit his notions of what constitutes safety, beauty, and an adequate dividend. The task is, indeed, no easy one; and even were it far easier it is a long cry, when there is but little money to spare, from conversion to application. If our leading local authorities take the matter of tramways in hand with the same energy as they have the matters of gas, water, and electric light works, conversion may, it is true, be followed by the immediate application of the new ideas to practical cases, and we may very possibly witness an electric tramway boom comparable to anything of the kind that has happened across the Atlantic. Meanwhile, the only thing to be done is to make due preparation, and as an aid to that end to purchase the dearly-bought experience of others at a cheap rate.

THE BOARD OF TRADE ELECTRICAL STANDARDISING LABORATORY.

(Concluded from page 667.)

The second Standard is that for one hundred volts, and is a specially designed multicellular voltmeter. The following is the official description of this instrument.

STANDARD OF ELECTRICAL PRESSURE.

CONSTRUCTION AND USE OF THE BOARD OF TRADE ONE HUNDRED VOLTS ELECTRICAL STANDARD.

The instrument is shown in plan and sectional elevation on the accompanying drawings. The letters refer to the paragraphs, no reference letters being required on the illustration.

It consists of:

Suspended Vanes.—(*a*) An arrangement of 10 parallel vanes, shaped like the moving portion of Sir W. Thomson's Quadrant Electrometer, fitted on an axis passing through the centre of gravity of each vane and separated by distant pieces to a distance of nine millimetres apart.

Concave Mirror.—(*b*) On the same axis is fixed the aluminium frame of a concave mirror 19 millimetres in diameter and about 61 millimetres focal length, which is held in the frame by means of three light phosphor-bronze springs.

Suspending Wire.—(*c*) This arrangement is suspended by means of a wire 0·05 millimetre in diameter and 18 centimetres in length, formed of an alloy of 10 parts of iridium to 90 parts of platinum, attached to the end of the axis above the mirror so that the axis hangs in a vertical line.

Horizontal Adjustment of Position of Vanes.—(*d*) The upper extremity of the suspending wire is fixed to the centre of a circular brass plate having teeth cut in the circumference, into which a tangent screw is geared so as to enable the end of the wire to be rotated in the horizontal plane for the horizontal adjustment of the vanes.

Vertical Adjustment of Vanes.—(*e*) The vertical adjustment of the position of the vanes is accomplished by the raising or lowering of the platform on which the circular brass plate mentioned above is pivoted by means of three screws for raising and three for lowering.

These screws regulate the distance of the platform above a similar platform fixed by means of three supports to the framework of the instrument.

Quadrants.—(*f*) The vanes are suspended so as to slightly enter at the zero position of the instrument into the spaces between two sets of 11 thin polished brass plates shaped as quadrants of a circle, which are fixed horizontally one above another to a vertical support. These two sets of plates are in metallic connection, and are carefully insulated from the framework of the instrument.

Vibration Checking Arrangement.—(*g*) In order to reduce the vibration of the suspended system, and the time which must elapse before an accurate observation can be taken, a thin horizontal brass disc is suspended in refined mineral oil contained within a glass vessel, by means of a wire attached to the lower portion of the axis of suspension of the vanes.

Outer Case.—(*h*) The suspended system and quadrants, with their supports, are inclosed in a brass case having in front of the mirror a rectangular window of parallel-worked glass. A hole is cut in this case for the insertion of a key fitting the squared arbor of the tangent screw (*d*).

Terminals.—(*i*) The terminals, by means of which connection is obtained with the vanes and quadrants, are fixed on a thick piece of polished ebonite projecting beyond the brass cover (*h*).

One terminal is in connection with the metal framework, the other is entirely insulated; and a tongue of brass or switch connected by means of a brass rod with the two sets of quadrants can be turned so as to make contact either with the insulated or with the uninsulated terminal.

Framework and Supports.—(*k*) The arrangement described above, forming the electrical portion of the instrument, is mounted near the apex of a framework of brass in the form of a circular arc which rests by means of three feet on a horizontal

Digitized by Google

slab of polished marble supported on a large block of Portland stone on a concrete foundation.

A screw thread is cut on the feet for accurate levelling of the framework, to which two spirit levels are attached.

These lines form the fiducial marks; that on the left of the observer giving the zero position, and that on the right the correct position for 100 volts pressure.

The distances from the mirror (b) of these tablets and of the

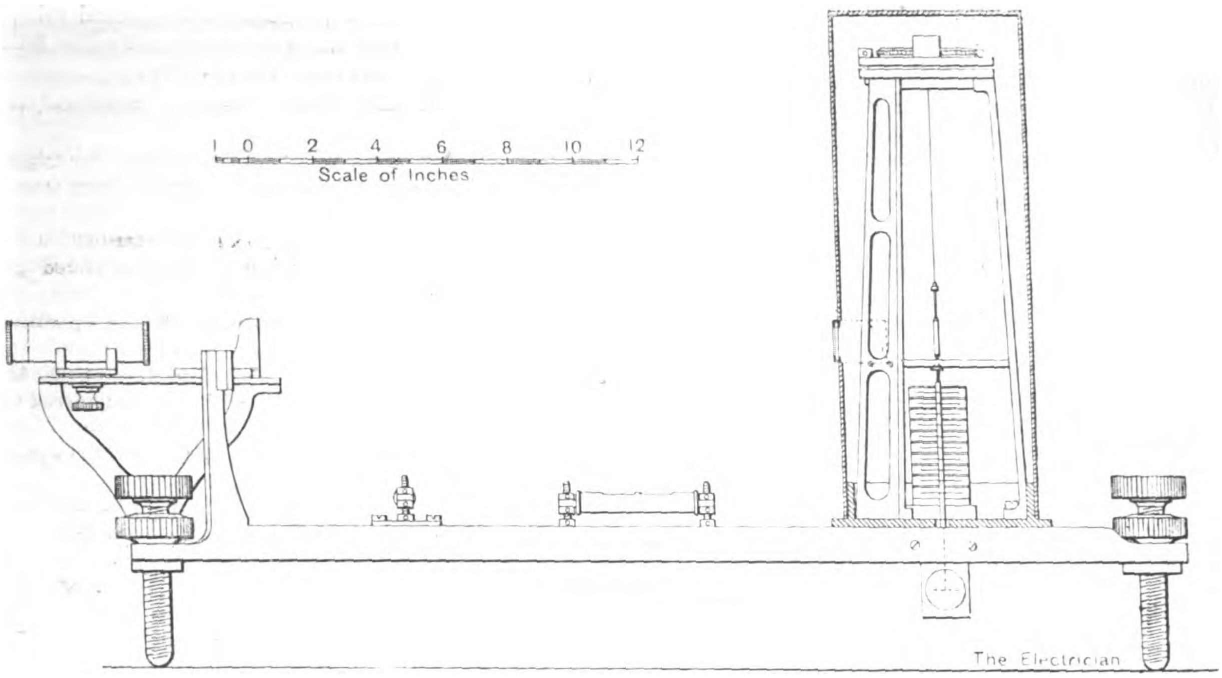

Fig. 1.—Side Elevation of the Volt Standard.

Eyepiece and Cross Wire.—(l) On a support attached to the centre of the curved portion of the framework is fixed the observing portion, consisting of a magnifying eyepiece in front sighting wire (l) is adjusted so that the image of the line on the tablet, when the mirror is at the proper angle, coincides with the sighting wire.

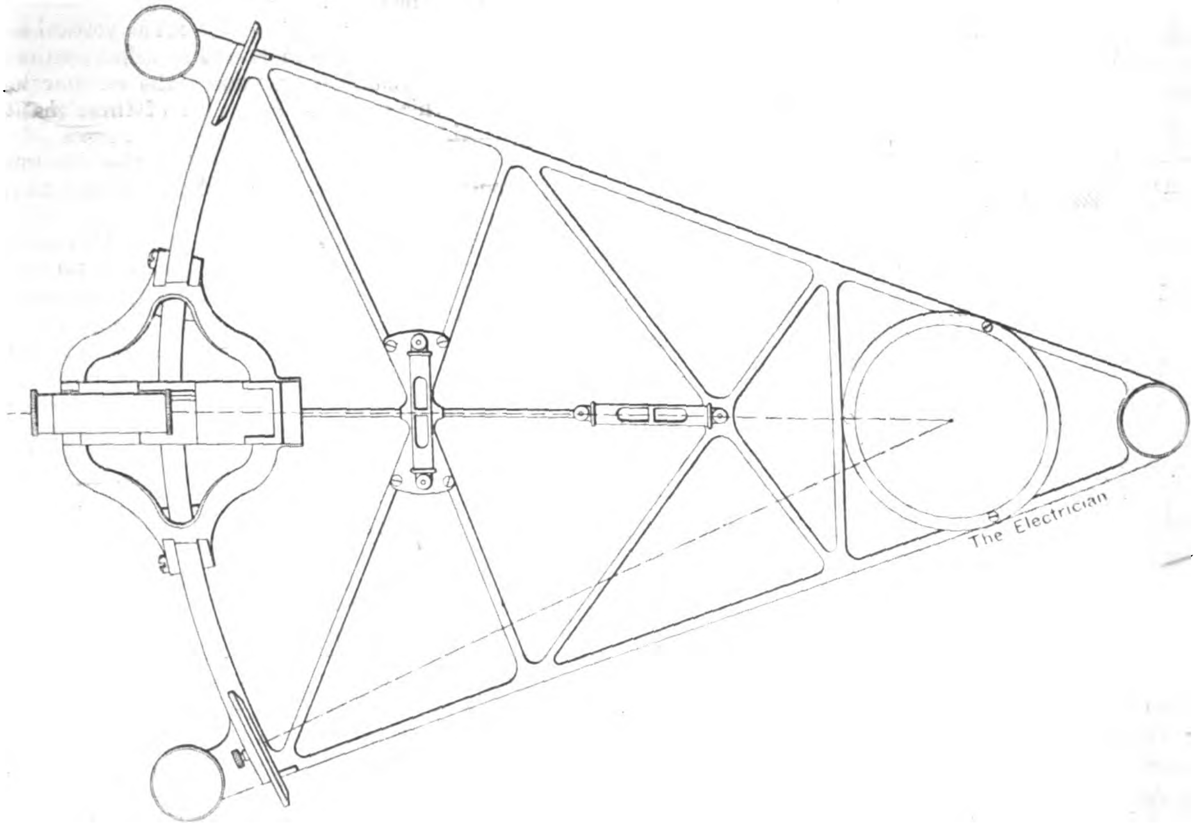

Fig. 2.—Plan of the Volt Standard.

and in the focus of which is stretched a vertical copper wire 0·06mm. in diameter.

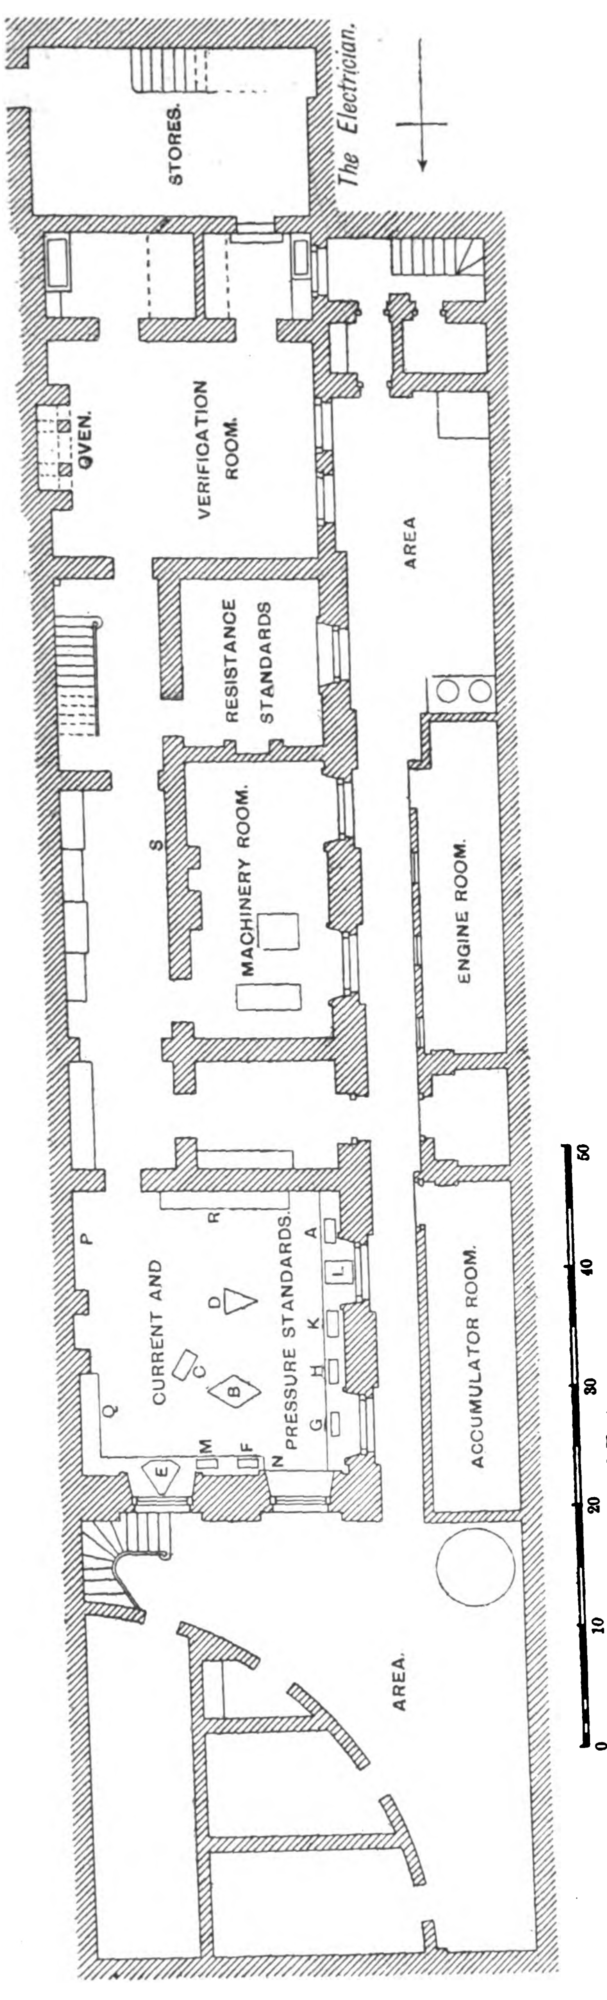
Fiducial Marks.—(m) At each end of the arc is erected a vertical support, to which is fixed a tablet of brass with the surface facing towards the mirror platinised. On each of these faces is engraved a vertical line.

Use of the Instrument.

Adjustments.—The instrument must be in accurate adjustment as regards level and position of the suspended system.

The vertical adjustment of the latter is obtained by trial. The vanes should be at equal distances from the quadrants above and below, this position giving minimum sensibility.

Digitized by Google



Scale of Feet.

FIG. 3.—General Basement Plan of the Electrical Standards Department of the Board of Trade.

The horizontal adjustment of the suspended system is obtained when the image of the zero fiducial mark produced by the mirror (*b*) exactly coincides with the sighting wire (*l*), the switch (*i*) being turned so as to connect the quadrants with the metal framework of the instrument.

(The levelling of the framework and vertical adjustment of the suspended portion of the instrument were carefully attended to when the instrument was first set up, and these adjustments have since that time remained constant. The horizontal adjustment of the suspended system requires occasional attention from time to time.)

Readings.—Arrangements should be made for obtaining a pressure which can be continuously varied from about 98 to 102 volts.

This pressure is applied to the 100-volt standard, and to the instruments to be compared with it, and is adjusted until the image of the fiducial mark indicating 100 volts pressure exactly coincides with the sighting wire (*l*) by observation through the eyepiece.

This coincidence is maintained, by adjustment of the pressure, if necessary, until the expiration of five minutes from the time of first applying the pressure, when, if there is no visible vibration of the mirror, the pressure is exactly 100 volts.

The general arrangement of the Laboratory is shown in the plan Fig. 3, and consists of the various rooms already enumerated (p. 665 *ante*). The accumulators in use consist of a battery of four large 61-plate Crompton-Howell cells, which are generally used two in parallel or the direct production of large currents, and 108 11-L E.P.S. cells. The large cells can supply currents of any amount up to 2,000 amperes for a short time, and are charged in series at the rate of 200 amperes. The E.P.S. cells are used for running the transforming machinery and for supplying continuous pressure up to 200 volts. The discharge rate is never allowed to exceed 22 amperes even for short periods. Current from the large cells is brought into the room containing the standards of current by mains consisting of flat copper strips, the lead and return being sandwiched together to avoid magnetic disturbance. A break is provided just outside this room for the insertion of regulating resistances, which for the most part consist of carbon rods with suitable terminals. The use of carbon in this connection has this great advantage in addition to that of handiness, that as the resistance diminishes with increase of temperature, the fall of current which would otherwise take place from the slight polarisation of the cells and the warming of the metallic circuit can be completely obviated by choosing suitable lengths and cross-sections of carbon. Great steadiness of even the largest currents for an ample time has thus been obtained. Fine adjustments of current are secured by the use of rheostats formed of carbon plates under variable pressure inserted either in the main circuit or as a shunt to the measuring instruments.

A large electric balance (A, Fig. 3), made under Lord Kelvin's supervision, is fixed immediately at the point of entry of the above-mentioned large mains. This instrument can read up to 10,000 amperes. Round two sides of the current and pressure standards room is fixed a concentric main of the same pattern as those used by the London Electric Supply Corporation for trunk mains from Deptford. The outer conductor is cut across at intervals, and large terminals clamped on at each side of these breaks to which the current-measuring instruments are attached, while copper bars are provided for short-circuiting every instrument. The inner conductor is only exposed at the two ends, where it can be similarly connected to the outer conductor, either through an instrument or by means of a short-circuiting strap. A complete anti-induction circuit is thus provided for current. A shelf of enamelled slate is carried on corbels let into the external wall of the building underneath the concentric main as a support for the current-measuring instruments. The Ampere Standard B is placed upon a stone pedestal near the centre of the room, and the auxiliary ampere balance C upon a similar adjacent support. The Volt Standard D, which really measures 100 volts, or one hekto-volt, occupies a third stone pedestal in the centre of the room. Another instrument of the same pattern is placed at E. On the shelves round the wall of the room are five sub-standard

Digitized by Google

Kelvin balances of the following ranges, 1 to 5 amperes (F, Fig 3), 5 to 30 (G), 30 to 120 (H), 100 to 600 (K), and 500 to 2,500 (L). The first two of these have aluminium beams. A composite watt-balance is placed at M. One of the remaining walls, R, is occupied by various pressure-measuring instruments for low pressures, and the fourth wall partly by pressure-measuring instruments for high pressures, Q, and partly by a switchboard, P, for regulating the transforming machinery. A highly insulated platform is provided for standing on when manipulating the high pressure instruments. On this board are a pair of Cardew voltmeters, supplemented by twelve of resistance tubes. Each of these is practically a complete Cardew voltmeter, but without hand movement and dial. Each contains the usual wires and pulleys under exactly the same "live" condition as in a working voltmeter. By means of these resistances, which can, of course, be independently checked and mutually compared, differences of potential up to 2,150 volts can be measured. A number of miscellaneous instruments are left in this room on the table R near the door. A "chain" of voltmeters—that is to say, a set of instruments ,the range of each one overlapping two others, as with the sub-standard ampere balances—will be placed here.

The chief work which has been done in this room is the comparison of the three standards of current, volt, and resistance. The standard ampere, as obtained by many repeated determinations by the silver voltameter, was discharged by the accumulators and passed through the Ampere Standard, the auxiliary balance, and through a hundred ohms in the resistance (N, Fig. 3), and gave a difference of potential of 100 volts, which was observed on the Volt Standard. The 100 ohm resistance is made of manganin, and is maintained at a constant temperature by oil circulated by a small electric motor, and by the circulation of water in an outer jacket. This hundred ohm resistance had to be compared with the Ohm Standard, the value of which was accepted from the British Association determinations. The volt was thus deduced from the corelation of the Ampere and the Ohm. The scale of the Volt Standard is long enough to include the pressures due to 69, 70 and 71 Clark cells, and by direct comparison, the value of the cell was thus determined. The work of carrying out this triple comparison occupied many months.

It may be said that while the Imperial Standard Yard and Pound have to be most carefully treasured, and if destroyed can never be actually recovered, physical units are not equally precious, and may be re-determined. All that is necessary for re-determining the ampere is to remember "three noughts three ones and an eight"—0·001118—the electro-chemical equivalent of silver, a formula not unlike "three feet three inches and three-eighths," the length of a metre. A current of about 0·8 ampere is kept continually passing through the Ampere Standard to keep it warm and dry. The period of a complete swing of the standard of current is about half a minute, and hence the need for an auxiliary balance, to act as the "finder" of a telescope.

Among the instruments at present in construction is a huge Cardew voltmeter of the horizontal pattern, with compound iron and brass tube, 10ft. long. This is fastened to the wall at S. This instrument will have no gear, and will be read optically.

The transforming machinery consists of a continuous current motor and an alternator with shafts in line and both keyed to a common pulley, while a continuous current high pressure dynamo can be run from this pulley by means of belting. By varying the exciting currents of these different machines a very delicate adjustment of the transformed current or pressure is obtained. There are, in addition, various alternating current transformers for giving a range of current up to 500 amperes and of pressure to 10,000 volts.

The room containing the Standard of resistance and Clark cells is a small room arranged to be kept at a uniform temperature of 16°C. In this room is a Carey Foster bridge, and Thomson reflecting galvanometer with a transparent scale. Profs. Kahle and Lindeck worked in this room for several weeks on the comparison of standards of resistance under the direction of Prof. von Helmholtz, and were quite satisfied with the agreement of the Standards with those of the Reichsanstalt. Prof. Carhart also made comparisons for the U.S.A. Standards Bureau.

The Verification Room is fitted with a concentric main running around three sides, slate shelves for the support of instruments; and a large fireclay oven 2ft. 3in. wide, 2ft. 6in. deep, and 3ft. high, with plate glass front perforated with holes for leads, is heated by gas, for testing instruments at various temperatures. It has been run to a very high temperature, but it is not proposed to use it for more than 30° C. This room is fitted up with secondary standards for the measurement of current and pressure up to the limits of instruments in common use. In this room calibration and tests of meters have been carried out. This work has nothing to do with the calibration and sealing of meters which is carried out by the London County Council, but relates to the approval of the patterns. Some twenty-four meters are now under test. In this room deci-ampere deka-ampere, and hekto-ampere Kelvin balances are employed.

Ammeters and other instruments will be calibrated here when the laboratory is ready for this branch of work. No official tests of this kind are at present carried out, but since the issue of the Order in Council, the question of opening the laboratory for the commercial verification of instruments has been under consideration, and a scale of fees is being prepared.

In the verification of instruments in this laboratory definite units and multiples of those units are dealt with. For instance, if an instrument reading to 100 volts is sent for verification at certain points, say 90, 95, and 100, the readings of those instruments when pressures of those amounts are applied are given, and not the values of the indications 90, 95, and 100 on the instrument. It is obvious that where a large number of instruments have to be checked this method is necessary for economy of time and power.

NOTES ON THE ANGLO-AMERICAN TELEGRAPH COMPANY'S 1894 ATLANTIC CABLE.

BY ARTHUR DEARLOVE.

The successful completion of this cable may be considered a fitting opportunity to review the progress made of late years in cable design as represented by the construction of this, the fifteenth, Atlantic cable. The development of telegraph traffic between Great Britain and America has rapidly increased, and the public demand for the quickest possible service has always been fully recognised by the Anglo-American Telegraph Company, who, to ensure such a service, recently determined to lay a new cable of exceptionally high working speed.

The Company's consulting engineers, Messrs. Clark, Forde and Taylor, were requested to design and make estimates for such a cable, and their instructions were that it should be capable of transmitting not less than 40 words per minute.

Since the introduction of automatic transmission on their cables, at the instance of the Company, by Mr. Herbert Taylor, early in 1888, the speed of working which, till then, had been governed by the rate at which the sending clerk could efficiently manipulate the keys, has been increased more nearly to the limits imposed by the electrical "constants" of the lines. In a core of given materials these "constants," as is well known, depend upon the dimensions assigned to the conductor and insulator respectively, and it is a matter of great importance commercially that their relative weights should be judiciously chosen.

Broadly speaking, the cost of the core is governed by the weight of the dielectric, and the working speed by the weight of the conductor, the latter, however, being limited by the necessity of maintaining, for mechanical and manufacturing reasons, a sufficient thickness of the insulator.

Subject to these conditions, the problem, therefore, is to provide the required working speed at a minimum cost, and the solution arrived at by the engineers was that the core should have a conductor weighing 650lb., insulated with gutta-percha weighing 400lb. per nautical mile.

Next, with regard to the mechanical construction of the cable, the sections given below (Fig. 1) are from photographs of the types actually laid.

Digitized by Google

The length manufactured was 1,952 knots, the total weight of which was over 5,000 tons. The most important type to which I shall specially refer is, of course, the one designed to be laid in deep water of from 1,000 to 2,500 fathoms (see Fig. 1).

For very good reasons the endeavour of cable engineers has been to combine great tensile strength and low specific gravity with durability, and until some new material other than steel and possessing the requisite properties is introduced, no marked improvement on the type referred to appears probable.

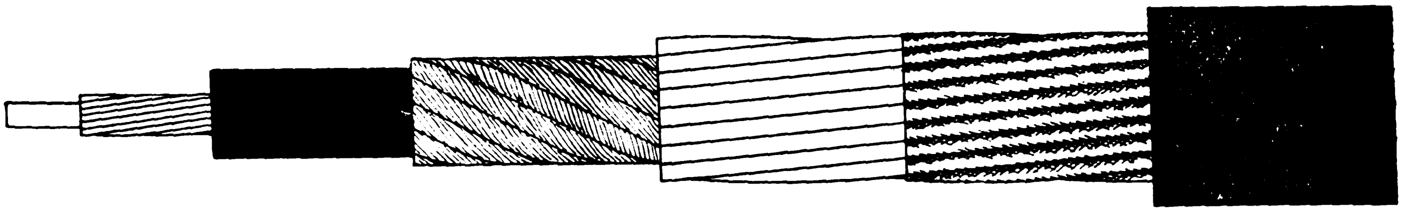
In the Sixties and Seventies the question of supreme importance was how to construct a cable that could be successfully laid in deep water, and on this point Company and contractor were of one mind; but in more modern practice, besides the above requirement, the telegraph companies and their engineers have insisted upon the necessity of a type which, though less easy to lay, is likely to possess greater durability and be more easily raised for repair after many years' submersion.

Formerly, it seems to have been considered that the merits of a deep sea type could be expressed in terms of the number of fathoms of its own length, hanging vertically in water that it could support without fracture. Now, the information so so-called "light cable" the strain due to friction may easily be greater than that due to the dead weight of the cable itself.

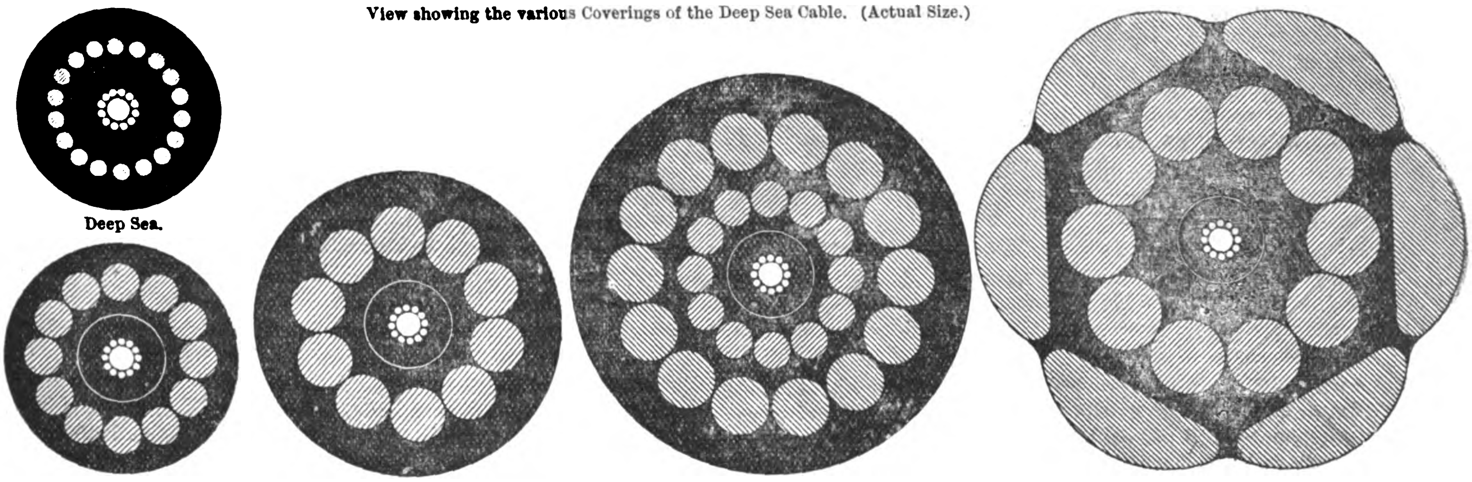
The following table gives the mechanical data of the Atlantic deep-sea types adopted in 1894 and in the seventies by the Anglo Company:—

1894 cable.		Atlantic deep-sea type of 20 years ago.
Sheathing.	18/14 steel, each wire compounded & taped.	10/13 homo., each wire covered with compounded hemp yarns.
Outer serving	Two tapes & compounds	One jute yarn whipping
Breaking strain	8·2 tons.	6·4 tons.
Elongation	4 per cent.	—
Weight in air	40·2 cwt.	45·0 cwt.
„ „ water	22·75 „	18·6 „
Specific gravity	2·30	1·70

The available strength of the 1894 cable is nearly 30 per cent. higher than that of the type composed of a combination of hemp and iron. Moreover, in the former each wire is guarded from corrosion by a gutta-percha compound, and further pro-



View showing the various Coverings of the Deep Sea Cable. (Actual Size.)



Deep Sea. Light Intermediate. Heavy Intermediate. Newfoundland Shore End. Irish Shore End.

Fig. 1.

expressed is no doubt of value, and a large number of fathoms (say, from 5,000 to 10,000) implies excellence from a paying-out point of view; but for picking-up operations the actual breaking strain of the cable as expressed simply in tons and hundredweights is regarded as being of at least equal importance.

Cables are not laid in water from 5,000 to 10,000 fathoms deep, and for obvious reasons never will be, and the condition on which the possibility of the recovery of a cable from existing

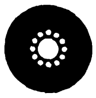


Fig. 2.—Core.

depths really depends, is the margin of strength between the actual breaking strain and the weight of the suspended portion of the cable.

The weight itself is only one of the factors of the picking-up strain; another factor is the friction between the cable and the water, which depends on the rate of picking up, and on the nature and area of the surface of the suspended part, but is quite independent of the specific gravity of the cable. In a tected by a separate tape. It is contended that for these reasons the chances of successful recovery after years of submersion have been materially increased.

As previously mentioned, a core of 650lb. copper and 400lb. gutta-percha was adopted. The section of it is shown in Fig. 2. The data below apply to this core, and, for comparison, corresponding data are given of the earlier core used for Atlantic cables.

——	1894.	1873 Atlantic.
Weight of conductor	650lb.	400lb.
Weight of insulator	400lb.	400lb.
Res. per knot in ohms laid	1·682	2·93
Cap. per knot in microfarads	0·420	0·353
Diameter of core	0·475in.	0·460in.
Breaking strain	1,000lb.	—
Relative earning power per unit of cost	1·55	1·00

Until it is shown how practically to construct a core having the properties of Mr. Oliver Heaviside's "distortionless circuit," a step in the right direction has been taken by liberally increasing the weight of the conductor.

Digitized by Google

With gutta-percha at six or seven times the price per lb. of copper, the advantages of restricting the weight of the former material are obvious; but another point which might be lost sight of is that the heavier conductor hardly affects the diameter of the core, so that its adoption does not sensibly increase the cost of the sheathing, or of the shipping.

It should, however, be borne in mind that the principle must not be pushed too far, and that suggestions in this direction should only be acted on under the advice of those having a practical acquaintance with the details of the subject.

A contract for the work was made between the Anglo-American Telegraph Company and the Telegraph Construction and Maintenance Company, on February 23, 1894, and the cable was manufactured and the ships loaded and ready for the laying of the main section on the 30th June.

The heavy types of the Irish shore end were laid in May. The expedition was in charge of Mr. F. R. Lucas, the engineer-in-chief to the contractors, whose steamers, the "Scotia" and the "Britannia," were employed to lay the cable.

Mr. Herbert Taylor and staff accompanied as engineer to the Anglo-American Company. The cable was laid from Newfoundland homeward, the operation being conducted by Mr. Lucas with great skill and judgment, under somewhat adverse conditions as regards weather. A very unusual amount of ice was met with, and the great prevalence of fog made it at times difficult, or impossible, to fix the position of the ships by observation. An average of 9 per cent. of slack was laid, and the retarding strain carried, when paying out at the rate of seven knots an hour, was between 17 and 18 cwt. per 1,000 fathoms of depth.

It will be seen that in dealing with this heavy type of main cable, it is necessary to have machinery provided with ample brake power, as in 2,500 fathoms the strain to be carried is 45 cwt., which, at a speed of seven knots, implies the absorption of energy by the brake equivalent to over 100 H.P. The cable was completed on July 27th, and the subsequent tests with galvanometer and electrometer showed it to be in a perfectly healthy electrical condition. Its length is 1847·54 nautical miles. During the thirty days after completion a large number of tests were taken, the general result of which is given below.

With the galvanometer the mean dielectric resistance during half-an-hour's test with both currents was } 55,580 megohms per knot.

With electrometer. After charging with 100 volts for half-hour. Mean of both currents.

Time, mins.	Loss of charge, per cent.	Calculated Res. per knot, megohms.
5	0·85	83,225
10	1·64	86,270
15	2·49	85,700
20	3·33	84,360
25	4·06	86,140
30	4·83	86,530

The average resistance of the core when tested at 75° F. was 686 megs. per knot after one minute's electrification.

The electrometer tests were taken with Ayrton and Mather's electrostatic voltmeter, designed for electric lighting measurements. This instrument was found to be very suitable for cable testing. Unlike the quadrant electrometer, it is quite portable, and will be found extremely useful on cables like the Atlantic, in which the prevalence of strong earth currents makes tests taken with the galvanometer extremely tedious and difficult.

The conductor resistance of the line was obtained by joining the distant ends of the four cables between Valentia and Newfoundland two and two, and measuring the resistance of the metallic circuit.

The total C R of the new cable thus determined is 3,107 B. A. ohms.

Having taken a special interest in the determination of the capacity of long cables, I give the results obtained. The method is now well known to cable electricians.

The following table of figures is typical of the whole series of 60 observations which were made, approximately 10 for each period of charge, the total mean is given. This mean gives a total capacity for the laid cable of 775·26 microfarads, or 0·4196 microfarad per knot.

Standard Cap. 80·1 Microfarads. E.M.F. 30 Volts.

Time of charge. secs.	Pole of Battery applied.	Slide reading at balance.	Earthing period secs.	Disch'rge in scale divisions D.	Equivalent value in slide reading of D plus or minus.	Corrected slide reading.
5"	Z	939	5"	20 L	4 R	935

50 words of five letters per minute. The theoretical speed of this cable, with a K.R. of $2{\cdot}42 \times 10^6$, taken from the writer's "Tables,"* is 48·8 words of five letters per minute.

Speed of Anglo-American Company's Cables in Five-letter Words per Minute.

	Attainable speed.	Actual working speed.
1873	30	28
1874	30	28
1880	25	24
1894	50	47⅗
Totals	135	127⅗

The whole four cables are duplexed, which practically doubles the working power of the lines.

The Anglo Company have, by adding this new cable to their system, placed themselves in a position for transmitting an immense amount of traffic with the least possible delay, and the Company are to be congratulated upon the recent addition to their property.

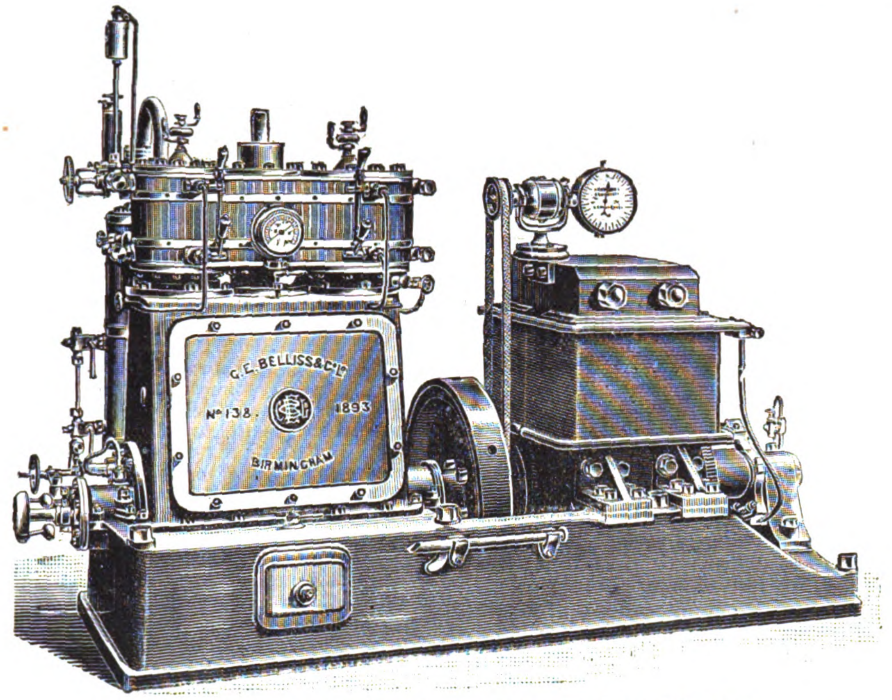
* "Working Speed of Submarine Telegraph Cables, &c." By Arthur Dearlove.

HIGH-SPEED DOUBLE-ACTING ENGINES.

The accompanying engraving illustrates one of the high-speed self-lubricating type of engines manufactured by Messrs. G. E. Belliss and Co. (Limited), Birmingham. These engines are used chiefly for electric lighting purposes, both for central stations and for ship work; and, at the present time, they have in hand a number for central stations, including Kingston-on-Thames, St. James and Pall Mall, Kensington and Knightsbridge, St. Pancras new station, Bedford, Ayr, &c., and, in addition, a number of other similar engines for driving direct fans and centrifugal pumps where high speeds are required.

The makers claim for this engine distinct advantages over the ordinary single-acting engines in both efficiency and simplicity. As will be noticed from the engraving, the working parts of the engine are enclosed by a neat cast-iron casing with large door, this being one of the chief features of the engine, whereby the working parts are readily accessible when required, and at the same time, by enclosing the engine, all the dirt and dust are kept from the bearings, and the oil, which is usually splashed about with an open engine, all passes down to the bedplate below. By means of a special system of lubrication, the oil is used over and over again, and a copious supply under pressure being delivered to every bearing, the engine works noiselessly and with very little wear, this being borne out by the statement of the makers that their engines have been at work for years without any necessity for adjustment of the brasses.

Another feature of the engine is the single valve gear with the two-crank compound engine, which makes a simple and compact arrangement, and allows of prompt governing. The point of cut-off, release, and compression, are all equally affected in both cylinders at the same moment. The makers state that at trials made with engines fitted with this type of valve, and an automatic expansion governor, the speed of the engine, on the whole load being suddenly removed, increases only about 5 per cent., and immediately settles to what it was with full load, being, it is said, absolutely isochronous. For the same reasons the powers are maintained practically equal in both cylinders under varying conditions of load, and, combined with the single-valve arrangement, the governing is necessarily prompt and effective.



Belliss Self-Lubricating Central Station Engine and Dynamo.

GOVERNING ELECTRIC LIGHT ENGINES.*

At various times and from different quarters we receive letters complaining of the difficulty which the writers find in obtaining governors which will satisfy the demands of the electrician. Apparently every centrifugal governor in the market has been tried, and not one gives complete satisfaction. Are we to assume that the governor wanted cannot possibly be made, or that it is beyond the powers of inventors to produce one? We think neither solution of the difficulty is sound. The much-desired governor is not forthcoming because the electric light engineers have not explained fully what they want, and—which is perhaps more to the purpose—why they want it. Let us endeavour to make good this deficiency.

The conditions under which electric light engines run are very trying. It is essential that they should always run at precisely the same speed, no matter what the load; or else the speed must be varied with the load in some definite ratio. Then the load varies from time to time through enormous ranges, and with great rapidity. Thus, for example, we have an engine of, say, 350 H.P. It is developing 150 H.P. Suddenly, by the turn of a switch, perhaps a mile away, the load is doubled. Now, if the engine is not prepared to take this instantly, without a check, the lights already on absorb-

* From the *Engineer*.

Digitized by Google

ing the 150 H.P. first named will blink, and possibly drop very considerably in intensity, for some seconds. This blinking the pubiic will not stand. It is a thing of all others to be avoided. Under some conditions of working, this engine, now with a load of 300 H.P. instead of 150, must make precisely the same number of revolutions as before. If it runs a little faster the first lights may have too much current; if a little slower, too little. Under other conditions of working, the engine must run faster with 300 H.P. than it did with 150, but the new speed must bear a precisely definite ratio to the old speed. Thus, then, we have two diverse sets of conditions. Under the first, the number of revolutions made per minute must remain unaltered, no matter what the load; under the second, the speed must bear an invariable ratio to the power. It will be seen that in either case the conditions are extremely trying.

When the ordinary centrifugal governor is used, no matter whether it acts on the throttle valve or on the expansion gear, a definite speed of engine accompanies each position of the governor balls. If the engine is making 100 revolutions and indicating 150 H.P., the circumference of the circle described by the centre of gravity of the balls has a given dimension. If the engine takes more steam and develops 200 or 250 H.P., then the circumference of the circle must be larger, for unless it is larger the throttle valve will not be opened further, but the balls cannot remain further apart unless the number of revolutions is augmented. Clearly, therefore, such a governor cannot comply with the condition of constant velocity of rotation of the crank shaft. Consequently, a centrifugal governor will not comply with one set of conditions. On the other hand, however, it might be made to comply with the second set of conditions, under which the speed is to vary with the power, if only a definite relation between the speed of the governor and the power could be commanded. It will not suffice to have a definite relation between the speed of the engine and the position of the governor balls. Only those who have tried to get a throttle valve or a Corliss governor to bear a definite relation in position to the power and the speed of the engine, can realise the difficulty of the problem to be solved. In practice a great deal has after all to be left to the engine driver, and he has to do the work that a properly-made governor would perform. All this, it will be seen, applies to the action of the governor in keeping the engine to the normal rate and correcting the small changes in speed due to a thousand and one trifling irregularities of load, friction, steam pressure, &c. The great initial difficulty remains untouched; namely, the power of the governor to deal with lightning speed with large alterations in load. What appears to be needed is a governor which the moment the speed drops or rises—say 1 per cent.—will open the throttle valve full or shut it absolutely, and will then by a series of very rapid alterations or oscillations open and close it through smaller and smaller arcs until the new position suited to the load has been attained. Something quite analogous to this is found in the gas engine, and it is by no means certain that the same principle might not be applied with advantage to the steam engine. Messrs. Brown Brothers make an anti-racing gear for marine engines. Mr. Weir has, we fancy, something of the same kind. The moment the engine tends to race, the inertia of a small moving weight opens a trigger, and the throttle valve closes. We have here the fundamental idea of a governor for electric light engines. The isochronal governor complies well enough with the conditions up to a certain point. The balls will remain in any position independent of the speed; it is only a change in speed that will cause them to move in or out, to or from the central spindle; but the isochronal governor is altogether too delicate a plant for the engine-house of an electric light station, and, besides, it is prone to "hunt" to a most distressing degree. On the whole, it appears to us that a modification of Pitcher's governor would best satisfy the conditions. This governor was at one time largely used by Fairbairn for regulating cotton-mill engines. The principle involved is very simple. A piston driven by the engine works up and down in a cylinder, and pumps air under another piston in a second cylinder. The air escapes through a snifting cock. The piston rod of the second piston is jointed to the throttle valve. If the engine runs too fast the air cannot get away in sufficient quantity through the snifting cock; the second piston rises and shuts off steam. In the same way, if the engine runs too slowly, the second piston sinks and opens the throttle valve. By substituting water for air the whole apparatus can be reduced in dimensions, and a very obvious modification will put the governor into such a condition that the opening of the throttle valve may be anything for any speed, its position not depending on the speed, as is the case with the centrifugal governor, but on change of speed.

Whether the governor acts on a throttle valve or on the expansion gear seems to be a matter of no consequence, as far as governing is concerned. We have seen an expansion gear governor taken off and replaced by a throttle-valve governor with excellent results, and no appreciable difference in steam consumption. Throttle-valve governors generally fail because the valve is not properly constructed. There is no sort of relation between the area opened and closed and the position of the governor. The result is, of course, disappointing. The best arrangement, it appears to us, would consist in passing the steam through a circular orifice in a plate in which moves a cone. If this cone is sufficiently tapered a very long range of motion will be required to make any material alteration in the area opened for the steam to pass through. But if, instead of making the sides of the cone straight, we curve them, then it is obvious that we can establish what relations we please between the position of the governor and the area for steam admission.

It is quite beyond our purpose to go into matters of detail, our principal object has been to direct attention to a much-felt want. Some electric light engineers are, no doubt, satisfied; but we often find that the satisfaction is based on ignorance. They do not know what a first-rate governor could do for them. Engine builders, again, often say that if the engine does not govern properly, the conditions under which current is generated are at fault and should be changed. The electrician's answer is simply, in some cases, that he cannot change them, and in others that he will not. We have ourselves no doubt that any competent inventor who would take the trouble to master the whole question could produce what is desirable. But the thing will never be done if a cotton mill engine is taken as a standard. The conditions to be satisfied are in essential particulars totally dissimilar. In what respects, the would-be inventor will do well to find out before he does any scheming.

SIR: Your article upon this subject is valuable and interesting, but it may be doubted whether the subject is so much in need of the "competent inventor" as is assumed. It is right to say that "the thing will never be done if a cotton mill engine is taken as a standard" but there are high-speed engine makers who have given as much attention to the subject of governing as cotton mill engineers, and, as they believe, with as much success: it is only necessary to refer to the late Mr. Willans. You, apparently, intending to take a typical electric light engine, select one running at 100 revolutions per minute. Your argument is, of course, unaffected by the number of revolutions, but does not the selection suggest a turning of the eyes towards the cotton mill engine after all, in forgetfulness of the fact—about which, I believe, there can be no doubt—that of all the public electric lighting work in Great Britain, very much more than half is performed by high-speed engines running at from 350 to 400 revolutions per minute, and standing on a much better footing as regards governing than an engine designed to run at 100 revolutions only? Surely it would not be unreasonable to take an engine of the high-speed class as the typical electric light engine. The first point I would refer to in your article is the very useful demonstration of the inevitableness of some change of speed with a change of load, owing to the different position necessarily assumed by the governor balls. It were well if this fact were generally understood; there would be less asking for impossibilities. It is, however, easy to give an accuracy of governing quite sufficient for the purposes of an electric lighting station; a total variation of 2 per cent. between full load and a very light load—which means a variation of speed of less than 1 per cent. through any variation of load likely to occur in practice—is easy of attainment. The change from 150 H.P. to 300 H.P., which you consider, need not involve a greater change of speed than this, and certainly, if in any station the engines are run with a much greater variation of load than from full load to half load, there must be something so radically wrong, either in the design or in the management of the station, that all governing questions sink into insignificance beside it. The Continental blunder of using a very few large units of power, instead of a greater number of small units, is happily understood, and is generally avoided in this country.

Having in view important stations where direct-coupled alternators of large power are driven at high speeds by Willans engines, and where the working is reported to be absolutely satisfactory, one is tempted to wonder what class of plant it is which gives rise to the complaints of the electrical engineers which you refer to. If closer governing than is above described is required by any electrical engineer—though it is hard to understand why—the means for attaining it are quite well understood. It is only necessary to fit a Knowles supplementary governor to bring the main governor balls away back to the original position. There are places where this is worth doing, but surely electric light stations are not amongst them.

Of equal interest are your remarks upon sudden changes of load, and the avoidance of "blinking" in connection with them. You advise a governor which on a small change of speed shall absolutely close the stop valve or open it wide. Now this is what any really well-designed governor, such as that originally schemed by Mr. Willans, does; except that, for the avoidance of hunting, it never absolutely closes, but always leaves an opening sufficient for the passage of steam enough to run the engine light. The throttle valve is of such proportions that a very small travel covers its whole range from closed to open, and is produced by a correspondingly small movement of the governor balls. Your picture of the desired effect—"a series of very rapid alterations or oscillations"—suggests rather what one tries to avoid, though it is very likely to ensue if the change from full open to closed, or nearly closed, is produced by too small a movement of the governor balls. In other words, if the apparatus is too sensitive it will also be too delicate; it will move too easily, and the governor will hunt upon small provocation. To avoid this we must govern a little more coarsely, and substitute, say, 2 per cent. for 1 per cent. Nevertheless, it is comparatively easy to work to the 1 per cent. standard so long as disturbing causes, like varia-

Digitized by Google

tion of boiler pressure, grit in the valve, &c., are absent. But what should be pointed out is that when we have thus been given exactly what in your article is asked for we shall be no nearer to the desideratum—viz., the power to instantly increase the load from 150 H.P. to 300 H.P. without causing the lights to blink, and possibly to drop in intensity. No quickening of the governor action will help, for it already acts so quickly that in a slow-running engine the throttle valve may be shifted long before the next cylinder admission comes round.

The truth is that the interesting point you have raised is not a governor question at all; it relates solely and only to the flywheel. With such an increase of load as you suppose no augmentation of the next supply of steam to the first cylinder, in a compound or triple engine, can produce power enough at once to prevent a check to speed. That can only be avoided by storage of power. For the moment the full power cannot be obtained from the engine; it must be obtained from a heavy flywheel, and there is no other way of preventing the drop in intensity of the lights. Needless to say, the whole matter is merely one of calculation when the data are given. The smaller the permissible drop in speed, for a given change of load, effected with a given quickness, the heavier the fly-wheel must be. As a fact, there never ought to be a serious "blink" in the lights, because there never ought to be a change both great enough and sudden enough to cause one. An instantaneous addition of 150 H.P. power to the load is scarcely conceivable in any lighting station, or if conceivable, it implies a plant of great size, giving an output compared with which 150 H.P. is small. Let it be borne in mind that the supposed difficulty hangs upon the word "instantaneous"; if the change is spread over a few seconds even, the difficulty vanishes. An hotel or other large building may be brought on very rapidly, but scarcely instantaneously.

Engineers should recognise that in a great number of cases where they speak of good or bad governing, they really mean sufficient or insufficient flywheel power for the particular work in view, and nothing else.

Thames Ditton, October 2nd. MARK ROBINSON.

NOTES ON ELECTRIC TRAMWAYS IN THE UNITED STATES AND CANADA.*

BY H. D. WILKINSON.

During the period of the Chicago Exposition last year I had opportunities of looking into systems of street traction in that city, and of discussing points of immediate interest with engineers from different cities whom it was my privilege to meet.

For several weeks previous to the opening of the Exposition the scene for miles round was one of the greatest activity in the construction of street tramways, centring from all districts on the south side, and forming connections from the city main cable car line. The continuation of the elevated steam road to the Exposition along Sixty-fourth-street was also a smart piece of work, including the erection of six stations and a pin-connected truss bridge across the Illinois Central Railroad track without obstructing traffic. Immediately this line was finished, trolley wires were strung underneath the girders, and the previous horse car lines, which had grown totally inadequate to the traffic, were converted into electric lines. The motor cars were rarely without trailers, and in the busiest times of the day two, and sometimes three, fully loaded passenger cars were hauled. The term "fully loaded," when applied to cars in America, must be understood in its most literal sense. Besides all standing and sitting room being taken up inside, the drivers' and conductors' platforms are closely packed, and people cling to the outsides wherever there is the smallest foothold. More than this, I have seen cars on busy days with people sitting on the window ledges and climbing on the roof, and the back end of the car framework weighted out of shape and scraping the ground. After seeing one motor car hauling two or three trailers, with 250 people, at the rate of 10 miles an hour, on roads with no drainage and covered with mud, I was convinced that the practice of putting two 25 or 30-horse motors on one car—which would otherwise seem a waste of material and power—was not unreasonable. The full power is, of course, not always wanted, and can be regulated by the controller to suit the traffic; but it is most important to have motors that will stand extra heavy work when required, and need no attention. During the year the number of passengers on all lines in Chicago was about 288 millions, or an increase of 55 millions over the previous year.

The general type of construction in wide thoroughfares is with poles planted in the centre of the road between the double track, carrying iron brackets for the support of trolley and feeder wires, and the general appearance is far from unsightly. This is specially the case when every other post supports an arc lamp or cluster of incandescents and the brackets are ornamental. Span wires are only necessary at curves and in narrow thoroughfares. The entire track construction, including rails and wires, costs about £1,400 per mile, and the car bodies, with motor trucks complete, cost about £800 per car. For a line, say, of 5 miles of track, with 15 cars, the power station, including building and machinery, would cost about £5,000, and real estate and car barns about £3,000—bringing the total cost of equipment to £27,000. The revenue per car mile was from 20 to 30 cents, and the total running expenses 14 to 16 cents, or, on the average, about 60 per cent. of revenue.

The very energetic body of the American Street Railway Association is thoroughly representative, and its members, who are all engaged in tramway work, think nothing of travelling 1,000 miles to be present at their annual conventions. At these gatherings, which occupy three or four days, original papers and reports of investigations consigned to committees at the previous meeting are read and discussed. An exhibition of manufacturers' supplies is also held at the same time, and new electric cars of all kinds are put on the town lines and run on regular service. Members practically own the town during their stay; the largest hotels are full, rooms being taken by representatives of different concerns as temporary offices. The various companies and firms in the town send in invitations to visit power houses and works, books of tram tickets are distributed gratis, and the telephone companies place their lines at the disposal of members. Time will not allow me to do more than refer to the very pleasant participation I enjoyed in the last convention at Milwaukee, Wisconsin. The Papers read have appeared in our own technical Press, and are consequently well known. The supplies comprised car bodies, trucks, motors, controllers, fuses and heaters, track scrapers and sprinklers, steel rails, points and crossings, compressed mica, and overhead line gear of all descriptions, everything that could be put in motion being supplied with electric current. Each member received a small choice souvenir of his visit, the gift of the newly elected president, Mr. Henry Paine.

I now pass on to some of the questions which are absorbing attention, and to describe what I saw of the working of different systems.

The directions in which improvements are sought comprise chiefly—

1. Better construction of road beds and tracks;
2. Better provision for the return circuit;
3. More uniform distribution of potential along the route.

Further, in the power house, the chief questions are in the driving, governing, and safety devices, the best proportion of power between engine and generator, and the problem of fly-wheel inertia.

Beyond these there are the questions of practical and economic systems of delivering energy to cars in cities and crowded portions of towns, such as by the storage battery or underground conduit; and for long-distance transit the use of synchronous or of two or three-phase motors with transmission of current by underground feeders at high-tension.

Some of these questions have given rise to much discussion in America, and most of them have more or less a bearing upon the development of electric traction in our own country. It appeared to me, therefore, that I could in some measure further the progress of the industry in this country by making such observations and inquiries on the present working of tramways in the States and Canada as affected the immediate future; and I looked forward, on my return to the duty as well as the pleasure of bringing the results of these investigations before the members of this Institution.

During the summer of last year I visited the cities of Detroit and Milwaukee, and in November—on the completion of my official duties at the Exposition—the cities of Toronto, Montreal, Buffalo, Cleveland, Cincinnati, Pittsburg, Washington, and Philadelphia; making also a complete examination of the electric railroad recently erected on the Canadian side of the Falls. From the officials of the various companies whose lines and plant I investigated I met with the greatest courtesy and cordiality, and the expressed wish, not only on the occasion of my visit, but at any future time, to furnish such information as might be desired.

With regard to road bed and track construction there is not much to be said, as the general conditions in America differ considerably from those in our own country. In many cities, and especially in the suburbs of large western cities, the rails are allowed to project above the road bed 1in. or 2in., making very rough travel for other vehicles. In fact, the iron road is counted of the first importance in inducing people to live further out of town and build on the prairie, while the road for the use of ordinary vehicles is of only secondary consideration. After a few years, as property goes up in the district, a better foundation is put in, and the roads are levelled up to the metals by paving blocks or glazed bricks. Whole suburbs spring into existence in the wake of the electric tramway. Enterprise in promoting schemes is chiefly due to estate holders seeking to raise the value of their property, and it is remarkable that municipal corporations have given away important concessions for very trifling sums. These concessions after a few years generally become very valuable, and bring a good return to those who have sunk capital and taken risk; but it is now becoming

* This Paper will be discussed early in the course of the next session of the Institution of Electrical Engineers.

Digitized by Google

more usual for corporations to look ahead and put in clauses that shall let some percentage of the profits come in for the improvement of the streets.

Practice in the western cities of America is chiefly with T, flat, or step rails, spiked down to wooden cross-ties or sleepers; but on the best lines and in most eastern cities the channelled girder rail as used in England has been adopted on account of smoother travel, less noise, and a flush road surface. The English construction of concrete foundation has been followed on some lines, using a 9in. or 10in. girder rail. The tendency now in the States is to put in very heavy girder rails (90lb. or 100lb.), spiked to wooden sleepers placed at about 2ft. centres, which allows a good deal of spring in the track, and tends to loosen the bond contacts. Some 72lb. channel girder rails I saw in progress of laying had grooves 1⅛in. wide by 1in. deep. The height and base both measured 6in. There was first an 8in. foundation of concrete, upon which the sleepers (6in. by 8in.) were laid at 2ft. 3in. centres and then grouted in. Sand was then tamped round the base of the rails to the depth of 2in., upon which the paving blocks were laid. The points and special work were of cast steel.

The question of returning the current direct to the power house with as little leakage and loss in voltage as possible, is one of the most important in street railway problems. Excluding for the moment insulated returns, the paths open for the return current from the cars to the power house are—

1. By the rails and return feeders;
2. By supplemetary wires;
3. By the earth;
4. By metallic pipes and cables laid in the earth.

The return feeders include not only those cables connecting the nearest point on the rails to the generators in the power house, but cables brought in from more distant points of the line, as the configuration of the same and the load may require. In this matter everything depends on the position of the power house with regard to the route of the line. The primary object in their use is to lessen the voltage losses at the distant portions of the line; but in some districts their use has been largely extended, in order to prevent electrolytic effects on gas and water pipes. The remedy for the latter is clearly to provide a metallic return of ample conductivity, and while on modern lines improved bonding has done much to effect this, the addition of return feeders has had the desired effect in older and badly bonded lines. In Cleveland, Ohio, for instance, I found a very extended use of return feeders, and I was informed by Mr. Charles W. Wason, Vice-President and electrical engineer of the East Cleveland Railway Company, that he had resorted to their use entirely on account of electrolytic troubles with the water pipes of the city, with the result that the action ceased, and, in addition, about 25 per cent. of the voltage was saved. Some idea of the advantage of a saving in volts, apart from the consideration of speed of cars, can be gained from the fact that the current reached 3,000 amperes, and that for, say, 50 volts lost on the line every 1,000 amperes means a continuous loss of 70 H.P. The return feeders in this city are carried overhead, and are connected by riveted joints to the rails at about every 500ft. In Buffalo, also, I observed an extensive use of return feeders, carried undergound with the outgoing feeders within the city limits, but overhead further out.

Coming now to bonding, I have seen many different specimens of this work, and have some samples here to-night for the members' examination. One form of bond joint (Fig. 1) consists of a steel nipple bored to fit the bond wire, and tapered and slotted at one end. This screws into the rail, and the nut screwed up tightens the wire in the nipple, and the nipple in the rail. This was introduced by Messrs. Stern and Silverman, of Philadelphia, and is used on the lines of the Electric Traction Company of that city, the bond wires being passed two or three times through the rail outside the fish-plates to obtain the necessary conductivity.

There are still many very imperfect bonds in use, such, for instance, as that with copper or iron rivets, and soldered bond wire (Fig. 2), of which I have a specimen here. In heading the rivet the soldered joint is frequently loosened, and the bond rendered useless. The channel pin bond (Fig. 3), of which I have a specimen here, is in very extensive use; but a great defect in this device is that it cannot be riveted or made to completely fill the hole, and corrosion takes place in the interstice. The channel pin is used for the double bonds on the Lynn and Boston line, as shown in the illustration (Fig. 4). Another bond is the taper spring steel cap (Fig. 5), which is fitted on the end of the wire and driven into a hole in the web of the rail slightly less than its own external diameter. A similar bush joint, but formed as a sleeve or socket, has been in use some time on double bonds, as in illustration, and promises well (Fig. 6). A considerable improvement consists in making the bond wire in one piece, with shoulders for riveting formed at each end on the wire itself. This device (shown in Fig. 7) is due to Mr. McTighe, of New York, and has been very largely used. The advantages of this plan are that clean, water-tight, and air-tight solid metallic joints are obtained, and that the bonds can be made of any size wire. Mr. McTighe prefers to use these in short lengths of 12in. inside the fish-plates instead of the usual length of 30in., thus saving 40 to 50 per cent. in bond resistance. The short bond cannot be fixed to the web of the rail on account of the fish-plates, but is either attached to the tread or the base, the latter being the better point of attachment, as the bonds are soon worn away when on the tread. This bond, however, sooner or later becomes loose, owing to the difference in the coefficient of expansion of copper and steel, and, this being followed by galvanic action, the resistance, which at first is slight, rapidly increases at the joint. Some provision by which solder could be run in might add to the certainty of this joint, the ductility of the solder taking up the unequal expansion and contraction.

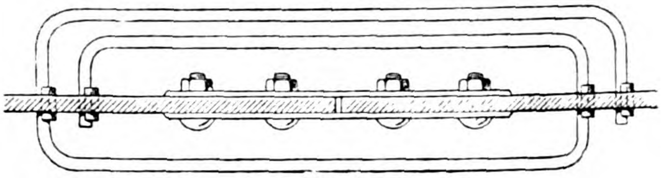

Fig. 4.

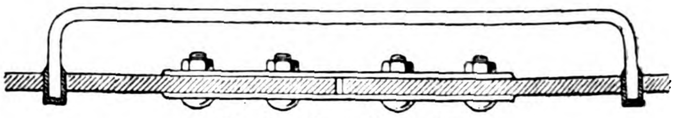

Fig. 5.—Taper Spring Cap.

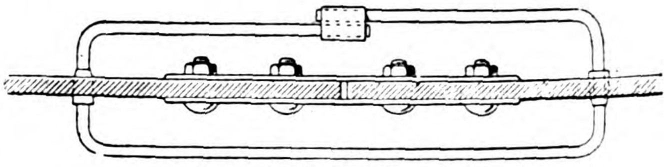

Fig. 6.—Split Steel Sleeve Bond.

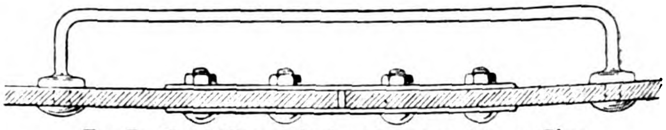

Fig. 7.—Bond Wire with Shoulder Riveted in one Piece.

Some of the older lines in the States, laid before the value of good bonding was appreciated, show an enormous loss of voltage from this cause. I was informed that on an old line in Richmond, Virginia, the bonding was done by No. 6 iron wires, and the same bonds used for a recent extension of 2½ miles, with the result that of 500 volts put into the line not more than 210 appeared at the distant end. The matter was investigated in consequence of bad working, and good copper bonds substituted for the iron wire, with the result that the loss was reduced to 5 per cent.

Bond wires are subject to corrosion by electrolytic action, especially in alkali soils. The wires, consequently, become thinner and conduct badly, and some of the current is shunted round the joint to earth, thus increasing the corrosion. Again, when the wires get very thin they become heated and fuse, thus throwing extra load on other feeders. I was informed that the action was

Digitized by Google

prevented by painting the wires, or coating them with shellac and asphaltum. The section or number of bond wires has, of course, to be increased nearer the power station.

The conductivity of the return circuit has been increased on some lines by the use of a supplementary wire, which is usually of bare copper ⅜in. or ½in. diameter, laid along the centre of the track. Cross connections from all bond joints are made by copper wire twisted and soldered to the supplementary wire, and on double tracks the supplementary wires of each track are connected every 30 yards. I saw new lines being laid with these wires in Chicago and Detroit, but I have also seen lines freshly opened up where the supplementary wires were considerably corroded, and was informed that their life was about two years. There were so many joints in the system, the wires used were so small, and were of such poor conductivity in comparison with a well-bonded rail, that the expedient appeared to me to be temporary and unreliable. In fact, I gathered that one of the chief uses of the wire was that its presence allayed to some extent the anxiety of the city authorities, otherwise harassed by water and gas pipe corrosion.

I next come to the earth as a return. I found that earth connections were made on most lines at their lowest points and at the power house. Such connections were made by sinking old car wheels or driving rails or pipes in moist earth, and making as good a connection therefrom to the rails as possible; but, from all I could learn, not much reliance was placed on such returns. The extremes of weather no doubt have something to do with it, as hard dry earth is a bad conductor. Even wet mud, in comparison to the rails, is a poor conductor, as is evidenced by the brilliant arcing at the wheels of cars running on a muddy rail. In the *Street Railway Journal* for last December, some tests by Mr. James D. Rostron, chief engineer of the Union Railway Company of Chester, Pa., bearing upon the conductivity of the earth as a return, were published. Mr. Rostron obtained an average of 285·5 amperes through the track and supplementary wires, 12·8 amperes through the city water mains, and only 0·51 through the earth plates sunk in creeks. If this is confirmed by further tests, it shows that the conductivity of the earth as a return is not high, but depends upon

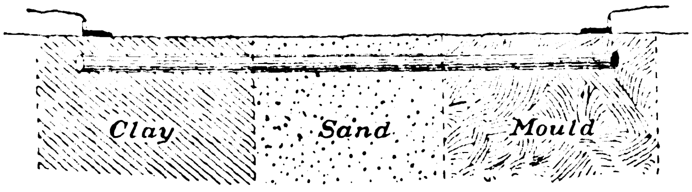

FIG. 8.

the presence of metallic conducting matter within it. While in Chicago, I made some tests to ascertain the approximate conductivity of the earth, and the difference of potential required to force current through pipes not metallically connected to a circuit. I laid some lead and iron pipes in earth, and at 1½in. distance above them I placed two iron plates as electrodes, 6ft. apart. Each plate offered 20 square inches of surface, and the current passed partly through the 6ft. of earth from plate to plate through clay, sand, and mould, and partly through 1½in. of earth at either end (clay and mould), and along the pipes (Fig. 8). I expected the resistance of the latter part would be almost nil, and, as I had 120 volts at disposal, I first put a resistance in series of four 105-volt lamps in parallel. I found, however, that the earth resistance was far more than I anticipated, and I removed three lamps with very slight increase of volts on the remaining one. The current was then half an ampere, and the earth absorbed 20 volts. A few days after, I obtained current from a 200-volt circuit, and put the four lamps on again. I then had 2½ amperes, with 100 volts absorbed by the earth. After keeping the current on for two weeks, the pipes were taken out, and were found to have a pitting of white scale in places at the negative ends. The scale was in white lumps, which, upon being scraped off, revealed the starting of little holes about 3-32nds of an inch diameter. This proved that some of the current, if not almost all, had passed by the pipes through the 3in. of clay and mould. While I attribute this high earth resistance to the clay, which had set hard, I am still of opinion that the earth has more resistance than is generally imagined, and that to attract current in anything but very minute amounts from a well-bonded rail to earth requires special conditions, such as deeply sunk plates, metallic connection to pipes, the ground saturated with moisture, or an excessive density of current in the bonds. I was informed by Mr. C. H. Morse, the city electrical engineer of Cambridge, Mass., that in some tests he made at Saginaw, Mich., for the gas company there, he was surprised to find that pipes were eaten away in two or three months under a return current which did not exceed 500 amperes. The soil was, however, very moist clay, and the rails were connected to earth plates.

(*To be continued.*)

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *September* 28, 1894.

Fundamental Street Railway Patents.—The Courts have just disposed of the claims of Stephen Field and Dr. Wellington Adams as inventors of street railway traction. In the former case the claim was made for a combination of a dynamo, a circuit of conductors, a wheeled vehicle, an electric motor to propel the vehicle, and a circuit-controlling device on the vehicle. The Court decided that the improvements covered by the patent were only such as the public might have obtained by presenting its wants to a skilled mechanic. In the Adams case the application of an electric motor to an axle was broadly claimed, but the Court decided that none of the elements were new; the motor and its several parts, the car axle, the axle boxes, the field-supporting frame, and all other things mentioned in the claims were in use before the time of the patent. In the decision in the Field case the Court, by implication defines invention as follows: "But if the result of the skill of the artisan still shows the barrier of impracticability between the end sought and the result attained, an interval between theory and practice, a limitation upon further development; while the alleged inventor, by the exercise of a discriminating faculty, distinguishes difficulties and estimates their proportions, and breaks down the barrier, or bridges the interval, or stretches beyond the limitation, by an instrumentality which, in the very facts of its construction and operation, by the adaptation of its mechanism to the end sought, suggests design; then he has contributed something of creative thought, he has invented this new instrumentality, his contract is valid, and his monopoly should be sustained." The above patents, particularly that of Field, were but a few years ago considered of value. Since then, however, the courts have taken a more just view of what constitutes invention, with the consequence that the professional inventor finds himself becoming more and more restricted in the exercise of his vocation. By professional inventor is meant one of the class which came so strongly to the front during the palmy days of electrical development, and whose skill lay in drawing up and passing through the Patent Office claims on obvious applications.

CORRESPONDENCE.

WATER-POWER IN GREAT BRITAIN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As a constant reader of your valued journal, and one who has been for many years interested in hydraulics, I read with great interest your article on "Water-Power in Great Britain" in your last issue, and I send you a reprint of a few notes I made on the same subject to the Royal Scottish Society of Arts. From your description of the water-power at Powick, it certainly does not seem to be so favourably situated for the continuous production of power as one might expect; but this is, as you say, not from want of water, but from excess during floods. Now the whole question is, why the floods? As a resident on the banks of the Severn for a number of years, I am well acquainted with these periodic ebbs and flows.

It is simply a question of storage. The damage done every winter by one of these floods would go a long way towards the cost of reservoirs, that would make excessive flooding a thing of the past. I would that everyone that is interested in water power could know what has been done at the Shaw's Water Works, Greenock, and the great source of revenue that has resulted from a judicious water storage. The rain fall is greatest in the hill districts, where the facilities for constructing reservoirs are greatest, and the whole question of conserving our water is fast becoming a national one. We have done less as a nation than any other, I believe, to make use of the forces of nature, and I hope that the engineers of the Worcester lighting scheme, who have been bold enough to make such an advance in the utilisation of water power may be rewarded with success.

Digitized by Google

As a case of what may be done in an entirely different direction, I have recently erected a turbine not 30 miles from Edinburgh, with a fall of 800ft. A reservoir was formed on the hill side, the average flow of water being about 50 cubic feet per minute. This water is brought 1¼ miles in a 6in. pipe for distillery purposes, and, by simply connecting a special high pressure turbine to the end of the pipe, 30 to 40 H.P. is obtained nearly all the year round, and the water after delivering up its power is allowed to flow into tanks for use in the works. The power alone at the low value of £8 per horse power per annum, is worth over £300 per year, and nearly double this if the power could be used night and day.

This is a solitary instance of what could be done in hundreds of cases did proprietors realise the value of water for power.—Yours, &c., JOHN RITCHIE.

Waverley Engineering Works, Edinburgh, near Abbeyhill Station, Oct. 9, 1894.

LEGAL INTELLIGENCE.

Braulik v. Sharp and Kent.

The proceedings in this matter were fully reported in *The Electrician* of September 7th. The plaintiff, Mr. G. Braulik, of Upper Thames-street, London, claimed in the City of London Court the sum of £2. 2s. 6d. for goods supplied to the defendants, Messrs. Sharp and Kent, of Connaught-mansions, Victoria-street, Westminster. The defendants' answer to the claim was that the goods were bought "on appro.," and this was admitted by plaintiff's traveller, but his evidence was to the effect that it was explained at the time the goods were left that if the defendants wanted to return the goods this must be done in a fortnight or three weeks. The defendants had, however, kept the goods for twelve months, and plaintiff held that this was quite contrary to the undertaking given to his representative at the time the goods were left with the defendants. A witness for the defence said that when goods were bought "on appro." in the electrical trade, they frequently remained with the intending customer for a period of six months. After hearing further evidence, the jury characterised the contention of the defendants as absurd, and not in accordance with the practice of the electrical trade. A verdict was, therefore, given in favour of the plaintiff for the full amount claimed, with costs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The 1894 Edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK contains 1,000 closely-printed pages, and several new and useful features have been added. The price of the Directory and Handbook, from October 1st, is 5s. post free; abroad 5s. 6d. *The 1895 edition is in active preparation.*

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell, with this title, will be ready in October. It will contain the latest information respecting the application of electric energy to mining purposes, in which the author has had much experience. The book is well printed, on good paper, and will contain nearly 250 illustrations, a large proportion of which have been specially made for the book. The price is 10s. 6d., post free 11s. (abroad 11s. 6d.). Orders can now be sent in.

"THE WORK OF HERTZ."—The lecture delivered by Dr. O. J. Lodge at the Royal Institution on June 1st is reprinted with corrections and additions, and many original illustrations, price 2s. 6d. net.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., will be ready next week, handsomely bound, full of original illustrations, designs, initials, &c. Price 7s. 6d.

TENDERS INVITED.—The Postmaster-General invites tenders for the supply of red fir telegraph poles, and for creosoting the same. Further particulars are to be found in our advertisement columns; and forms of tender, containing all particulars, can be had on application to Mr. Charles E. Stuart, Controller of Stores, Telegraph-street, London, E.C. Tenders have to be in by noon on Wednesday, the 31st inst.

——— Mr. John Annan, manager for the liquidator in J. W. Hobbs and Co. (Limited), invites tenders for the supply and erection of boiler house plant, engine house plant, switchboard, instruments, &c., for the electric light and power installation at the large block of hotel buildings now erecting on the Salisbury Estate, Victoria Embankment, and Strand, London, W.C. Plans and specification, &c., can be obtained of Mr. R. Hammond, consulting engineer, Ormonde House, Great Trinity-lane, E.C., on and after October 5th; and tenders must be sent in before Friday, October 26th.

TENDERS ACCEPTED.—Messrs. Crompton and Co. (Limited) have secured the order for the whole of the arc lamps for the Edinburgh street lighting.

——— The Halls Committee of the Southport Town Council have accepted tenders for the electric lighting of the Cambridge Hall and the Town Hall at a cost of £862.

——— The Southport Town Council have accepted the tender of the Fowler-Waring Cables Company (Limited) for the supply of 1,200 yards of high-tension cable for laying down in the Scarisbrick New-road, at £57 per mile.

——— The Bedford Town Council have given the contract for fitting up the Town Hall for the electric light to Mr. H. Bacchus, for the sum of £126. 18s., and that for similarly fitting up the Corn Exchange to Messrs. Kilpin and Billson, for the sum of £166. The Electric Light Committee made no recommendation to the Council on the tenders received, as they thought it better first to have plans prepared by Mr. F. H. Medhurst, and a resolution was proposed to that effect by the Chairman of the Committee, but was afterwards withdrawn in favour of an amendment that the work be divided as above mentioned.

——— The Free Libraries and Museum Committee of the Sheffield Town Council have accepted the tender of the Sheffield Electric Light and Power Company (Limited) to supply the cable, and to fix all necessary cable, wire, switches, distributing boards, &c. (not including fittings), for the electric lighting of the Weston Park Museum, for the sum of £174.

——— The Worcester Town Council have accepted the tender of Messrs. Paterson and Cooper for wiring and fitting up the waterworks for the electric light for £100.

TENDERS RECEIVED.—At a recent meeting of the Electric Lighting Committee of the Bury County Council, the Borough Engineer reported upon the tenders for the electric lighting plant and machinery, and it was resolved to give an opportunity to the whole of the persons originally tendering to submit fresh tenders for the continuous-current plant already adopted, and to extend the time for tendering to the October 15th.

SALE BY AUCTION.—Readers are reminded that the sale of modern fixed plant and machinery at York-street Works, Lambeth, S.E. (owing to the removal of Messrs. W. H. Allen and Co. to their new works at Bedford), takes place on Wednesday next at 11 o'clock prompt. The sale will be conducted by Messrs. Wheatley Kirk, Price and Goulty. Further particulars will be found in our advertisement columns.

——— Mr. Geo. N. Dixon has received instructions to sell by auction, on Friday next, the 19th inst., at the Angel Hotel, Dolgelly, Merionethshire, the whole of the electric lighting plant used for the lighting of the town of Dolgelly, particulars of which are given in our advertisement columns. Further particulars can be had of Messrs. Harmood, Banner and Son, 24, North John-street, Liverpool, or of the auctioneer, 66, Hanover-street, Liverpool.

PLANT FOR SALE.—Messrs. Morgan Williams and King, of 39, Victoria-street, S.W., have for disposal electric lighting plant, of which further particulars are given in our advertisement columns.

APPARATUS FOR SALE.—An advertiser desires to dispose of some nearly new electrical instruments, particulars of which are set out in our advertisement columns. The instruments are all in the best condition.

APPOINTMENT.—We are pleased to learn that the Electric Light Committee recommend the City Council of Coventry to appoint Mr. G. S. Ram clerk of works to superintend the engineering portion of the contract for the equipment of the electric lighting station. Mr. Ram is well known as the author of "The Incandescent Lamp and its Manufacture."

APPOINTMENT VACANT.—The Electric Committee of the Belfast Corporation are prepared to receive applications for the post of assistant electrical engineer, at a salary of £120 per annum. Some further particulars are given in our advertisement columns, and applications must be sent in to Sir Samuel Black, town clerk, Belfast, not later than Tuesday, the 23rd inst.

REMOVAL OF WORKS.—Messrs. W. H. Allen and Co., of York-street Works, Lambeth, S.E., announce that they have removed their works to Queen's Engineering Works, Bedford.

REMOVAL.—Mr. Edward Robins, Assoc.M.Inst.C.E., F.S.I., late of Robins, Snell and Gore, has removed to 8, Craig's-court, Charing Cross, London, S.W.

AGENCY.—Mr. Geo. Schultz writes to us that he has terminated his connection with Messrs. Fossick and Co. (Limited), and has started in business as an iron and steel merchant and manufacturers' agent, under the style of George Schultz and Co., at 90, Cannon-street, E.C., where he will conduct the agencies of Messrs. Edgar Allen and Co. (Limited), John Bilsland and Co., W. Smith and Sons, &c., and will continue the business in electrical engineering material.

Digitized by Google

BANKRUPTCY.—A receiving order has been issued in the affairs of John Henry Brown, electric cabinet case maker, 16, South-street, and 16, Archer-street, Halifax. The first meeting of creditors is to be held at the Official Receiver's Offices, Townhall-chambers, Halifax, on Oct. 19th, at 11:30 a.m., and the public examination on Nov. 12th, at 11 a.m., at the County Court, Prescott-street, Halifax.

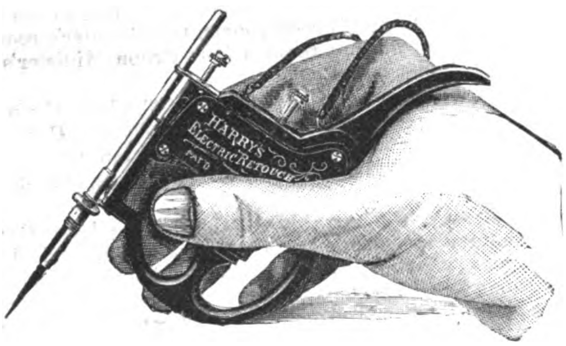
——— Mr. Arthur Shippey was publicly examined before Mr. Registrar Hope, at the Bankruptcy-buildings, London, last week. An account of the debtor's liabilities appeared in a previous issue of *The Electrician*. The examination was ordered to be concluded.

LIQUIDATIONS.—At a meeting of the shareholders of the Practical Electro-Plating and Enamelling Company (Limited), on September 22nd, at Coventry, it was resolved to wind up the Company voluntarily, and Mr. J. O. Asquith, 26, Trinity-churchyard, Coventry, was appointed liquidator.

EXHIBITION AWARDS.—The Elektrizitäts - Aktiengesellschaft vormals Schuckert & Co., of Nuremburg, have been awarded gold medals for their electrical exhibits at the Antwerp and Lyons Exhibitions.

TURBINES AND OTHER WATER MOTORS.—Messrs. Carrick and Ritchie are issuing an illustrated pamphlet describing their new turbines and other water motors for the utilisation of water for power purposes. The quarto pamphlet of 16 pages contains illustrations of vertical and horizontal arrangements of the Waverley turbine, and a table of powers and prices for single and double-discharge machines. Descriptions and similar tables are given of Ritchie's new patent double-gate turbine, the Gerard turbines, jet water-wheels and motors, sluice valves, &c., and an illustration is shown of a Waverley horizontal turbine with dynamo combination.

A PHOTOGRAPHER'S RETOUCHING TOOL.—In retouching photographic negatives the pencil will only mark well when stippled, and many mechanical devices have been tried for giving a reciprocating motion to the pencil. Nearly all of these are too heavy to hold



freely in the hand, but the little tool shown in the accompanying illustration is a marvel of lightness. A little electromagnet vibrates a keeper in the electric bell fashion, and sets the pencil in rapid motion. The instrument may be seen at the office of the *Photogram*, Farringdon-avenue, London, E.C.

INVALID PRINTERS.—The electrical and associated industries are probably as much interested in the printing as in any trade outside their own sphere, and it may be that a paragraph in *The Electrician*, calling attention to the needs of a very deserving charity, may meet the eye of some reader disposed to help. On Saturday last the foundation stone of a convalescent home was laid at Oxted, Surrey, by the Lord Mayor of London, in the presence of a large gathering, amongst whom was a gentleman known throughout the country for his thoughtful charity—Mr. Passmore Edwards. This home, when completed, will provide accommodation for 60 sick members of the printing profession, and funds are urgently needed to complete the structure. Mr. Passmore Edwards has generously given largely towards the building, and it now only remains for those in the printing trades and sympathisers from outside to complete the good work. The offices of the Caxton Convalescent Homes are situate at 33, Chancery-lane, London, W.C., and the secretary is Mr. Irvine.

"THE ENGINEERING MAGAZINE."—The October number of this magazine, now ready, contains articles on "The Evidences of a Revival in Business;" "The Cost of Living in Great Britain and the United States;" "Industrial Development of Chile" (illustrated); "The Ideal Steam Engine Governor" (illustrated); "The Management of Men in Mills and Factories;" "Modern American Machine Tools;" "Review of American Mining Law;" "Lightning and Lightning Conductors;" "Recent Architecture in Philadelphia" (illustrated); and "Probable Evolution of the Electric Railway." The editorial departments have been added to in number, and now include "Electricity," "Architecture and Building," "Civil Engineering," "Marine Engineering," "Municipal Engineering," "Mechanical Engineering," "Industrial Sociology," "Mining and Metallurgy," and "Railroadings," each under the charge of an expert, and containing notes (many illustrated) on subjects of interest. The Index to Current Technical Literature continues to form a feature in the magazine. The book is splendidly produced, and the illustrations are better printed, if that be possible, than hitherto. The October number commences a new volume (the eighth), and this is therefore a good time to make aquaintance with America's leading illustrated industrial magazine. The annual subscription is 12s. 6d. (U.K.), and 14s. abroad; single copies being 1s., or 1s. 3d. post free.

"TECHNICAL WORLD."—Under this title Messrs. Whittaker and Co. are publishing a weekly journal devoted to the advancement of technical education and to the recording, from week to week, of matters of interest to technical instructors and governing bodies of educational establishments throughout the country. The journal at present consists of 16 large pages, and is published at the popular price of 1d. In the current issue Sir Philip Magnus contributes an article entitled "Examinations: Are they a Mere Necessary Evil?" and Prof. Mullineux Walmsley an article entitled "Technical Education for Bakers." The *Technical World* meets an undoubted want, and should have a large sale.

NON-MAGNETISABLE WATCHES.—We have received from Messrs. Samuel Smith and Son, of 9, Strand, London, W.C., their newly-issued illustrated catalogue of watches, clocks, &c. This is one of the very few firms in this country who devote a special branch of their business to the manufacture of non-magnetisable watches, especially designed for use by electricians, electrical engineers, and others engaged in the construction and erection of electrical plant and apparatus. The catalogue is beautifully printed and well bound. Instructions are given to guide the purchaser in providing himself with the best watch for his special requirements, and the book, which consists of nearly 150 large quarto pages, contains, in addition, "wrinkles," with which watch buyers would do well to acquaint themselves. Particulars are given of tests made at Kew Observatory with Messrs. Smith and Sons' non-magnetisable watches, for which the firm have received the highest possible certificates. The firm have succeeded in obtaining the formation at Kew Observatory of a special class for the testing of non-magnetisable watches, and the Kew Committee have erected very powerful dynamos for the purpose. It would appear that watches under the new test undergo a 45-days' trial. Prices are given for converting ordinary watches into non-magnetic and magnetic-current-resisting.

ELMORE'S PATENT COPPER DEPOSITING COMPANY.—This Company inform us that they are now very busy in the manufacture of Elmore copper tubes for Her Majesty's Government and the leading railway companies. The Company claim that they are now able to supply Elmore tubes of 4in. diameter and upwards at a much lower price than brazed copper tubes. Copper sheet is also now manufactured by the Elmore Company.

"SAFETY" STAMP AND POSTAGE BOOK.—Mr. A. A. Coxe, of Ordsal Electrical Works, Salford, Manchester, has just introduced a safety stamp and postage book for general office use. The book is divided into compartments for the various stamp denominations, and claims to have the advantage of reducing labour and time in checking and balancing the use of postage stamps. It is further claimed to be a simple and effective check on stamp peculation.

OIL LAMPS.—Messrs. A. C. Wells and Co., of Midland-road, St. Pancras, London, send us descriptive circulars of their patent "Industrial" oil lamp, which is recommended as a cheap portable light for workshops, offices, factories, warehouses, &c. For positions and under circumstances where oil lamps are required, there are certainly many features of this lamp which take it out of the category of dangerous oil lamps. There are no glass chimneys used, and the lamp is entirely self-contained. By a simple contrivance the oil-well and wick can be lowered for refilling and lighting, so that the lamp has not to be taken to pieces. Mica is used in place of glass, and the container holds sufficient oil to last from eight to nine hours. Ordinary petroleum or kerosine is used for these lamps. By pressing the spring at the bottom of the lamp, the reservoir drops down and rests on the cross-bar, the spring at the same time entering the central-draught tube. After cleaning and lighting, this is lifted again, and the spring returns to its original position. The price of the lamp is 25s., and it is claimed to be of about 100 c.p. Many thousands are in use.

ACTON.—At the last meeting of the Local Board the Chairman said they had many inquiries from private individuals as to whether there was any probability of the electric light being installed in Acton, and that several firms had made tentative offers for the purchase of the Board's Electric Lighting Order. It was decided to allow the competing firms a month in which to send in their final tenders.

Digitized by Google

ALDERLEY EDGE.—The Local Board have decided to apply to the Board of Trade for a Provisional Order.

AUCKLAND (NEW ZEALAND).—The Brush Company are supplying a complete electric lighting plant for lighting the *Herald* office at Auckland, and the General Electric Company are supplying the whole of the fittings for the installation, which consists of 300 incandescents and 2 arcs. The specifications were prepared by Mr. J. Darling, of the Union Steamship Company's fleet, and the work is being carried out by Mr. A. G. Horton.

BARROW.—At the last meeting of the Town Council it was moved that the Selection Committee be instructed to take into consideration the question of electric lighting. It was urged that the Gas Committee was not the proper body to have the control of the electric light question, but that a new and representative committee should be appointed to go into the question impartially. After some discussion the motion was lost.

BASINGSTOKE.—At the monthly meeting of the Town Council on Thursday last week, Mr. Hammond's report on electric lighting was referred to the Electric Lighting Committee.

BOLTON.—Wednesday, the 24th inst., has been fixed for the formal opening of the new electricity works in Spa-road, and the turning on of the electric current from that station. Mr. Alderman J. Miles, J.P., Chairman of the Gas, Electricity, and Street Lighting Committee of the Town Council, will perform the opening ceremony.

BOMBAY.—The Crawford Markets have been fitted with an electric light installation by Messrs. John Fleming and Co. Twenty arcs and about 60 incandescents light the buildings, the current being obtained from two dynamos in the municipal workshops.

BRECHIN.—At a meeting of the Police Commission on Monday a report was submitted from the Lighting Committee in reference to the offer of Messrs. D. and R. Duke, to supply electricity to the extent of 1,000 c.p. from their dynamo for the lighting of St. Ninian's-square. The Committee had ascertained that the cost of cable, lamps, &c., would be between £40 and £45. The Committee recommended that the Scottish House-to-House Electric Supply Company having written offering, in the event of the town accepting the terms of that Company for the introduction of the electric light into the burgh, to take over the cable, lamps, &c., and to pay down full value for them, the Board should accept Messrs. Duke's offer, and vote £10 from the improvement fund towards meeting the cost. These recommendations were unanimously agreed to. The Chairman suggested that, in view of the electric light being brought in, the municipal buildings should now be wired, which could be done now for a cost of about £5, but which, if delayed, would cost a good deal more; and this suggestion was agreed to. Dean of Guild Ferguson also reported that correspondence had taken place with the Scottish House-to-House Electric Light Supply Company in regard to the proposal of that Company to apply to Parliament for a Provisional Order to supply electricity to the city. He had received a letter giving the terms at which the Company would be prepared to supply the light, and he moved that a special meeting of the Board be held on Monday to consider and dispose of the whole matter, and that meantime the Company's letter and terms be circulated amongst the members. The motion was unanimously adopted.

BUENOS AYRES.—The rumour is again afloat that a syndicate of British capitalists has been formed to start in Buenos Ayres works for the electric lighting of the city on an extensive scale.

CARDIFF.—The Town Council met on Monday, when it was stated that, although the electric light installation was on the point of completion, but very few applications had been received by the Corporation from private consumers. The Mayor complained of the delay that had been experienced in finishing the installation; the scheme had involved a great outlay, and entailed a serious loss on their capital expenditure. There was an unaccountable apathy on the part of the public in the matter. The Chairman of the Electric Lighting Committee confessed himself disappointed with the delay that had occurred, and with the small number of applications that had been received, but hoped that when the public buildings were illuminated with the new light a larger number of applications would come in.

CHURCH LIGHTING.—The electric light has been installed in the Bayswater synagogue by Messrs. Bergtheil and Young. The previously existing candelabra on the reading desk and in front of the ark are utilised as electroliers, and there is a total of 100 lamps of 16 c.p.——At Worcester, among the most recent customers for the electric light is St. George's Church, the wiring of which is being done to the specification of Mr. F. R. Davenport.——Messrs. Laurence, Scott and Co. have arranged and carried out the lighting by electricity of the "Chapel-in-the-Field" and several other churches and chapels in Norwich and district.——The parish church of Bexhill, Sussex, has now been fitted for the electric light, largely at the expense of the rector, the Rev. W. L. Grane.——A permanent installation of the electric light has been effected at St. Paul's Church, Church-street, Nottingham. Ninety 16-c.p. lamps are used, and several modifications of the usual switching arrangements have been adopted. The work has been carried out by Mr. J. Blackburn, of Nottingham, and has proved very satisfactory.——The Castle-gate Congregational Chapel, Nottingham, was reopened on Sunday after having been closed for decoration and the installation of the electric light. The work has been carried out by Messrs. Thomas Danks and Co. (Ltd.), of Nottingham, a total of 132 16-c.p. incandescents being distributed throughout the building.

COLCHESTER.—The Lighting Committee of the Town Council recently issued a circular to the inhabitants of the district proposed to be lighted in the first instance if the electric light were adopted, for the purpose of ascertaining whether the probable demand would justify the Council in laying down an electric light plant. The Committee reported at the last meeting of the Council that replies received were such as to cause them to recommend that no further steps be taken at present to carry out the provisions of their Order, and the recommendation was adopted.

DARLINGTON.—At the meeting of the Town Council last week the minutes of the Gas Committee included one referring to the Provisional Order the Council had obtained for the electric lighting of the town. Councillor Barron said they had been in communication with the Local Government Board, whom they had assured that when there was any demand for the electric light which seemed to warrant the outlay they would either supply it themselves or arrange for some company to do so under their control. He believed there was no danger of the Provisional Order being revoked.

DOUGLAS (ISLE OF MAN).—The *Isle of Man Times* calls upon the local authorities to set about introducing the electric light at once, in the best interests of the city. It appears that the electric tramway company have added an electric lighting installation to their service, and the advantages of the electric light over gas are at once apparent. The tramway company have lighted by a number of arc lamps a portion of their track at the north end of Douglas Bay, and the insufficiency of the gas lighting along the promenade is painfully apparent by comparison.

THE ELECTRIC LIGHT AT DOWNING-STREET.—The electric light was used for the first time on Wednesday evening in the Cabinet Chamber, the private secretaries' rooms, the Premier's rooms, and in the large hall and waiting rooms in the Prime Minister's official residence in Downing-street.

FAREHAM.—The sanction of the Board of Trade to the purchase of the undertaking of the Fareham Electric Lighting Company by the Local Board, has been received, on condition that the wires referred to in the 22nd section of the Order be placed underground.

FARNWORTH.—At the monthly meeting of the Local Board last week, an inquiry was made as to whether the Electric Lighting Committee was ever going to be convened. Another winter was at hand, without anything having been accomplished, and twelve months would have to elapse before application could be made for a Provisional Order. The Chairman said there would be a meeting of the General Purposes Committee shortly, when the matter would be considered.

HULL.—The Property Committee of the Corporation have decided to fit up the police-court for the electric light, at an estimated cost of £10.

INTERNATIONAL EXHIBITION AT AMSTERDAM.—It has been decided to hold at Amsterdam next year an international exhibition, illustrating hotel arrangements and accommodation for travellers generally, as well as means of transport by sea and land. One of the features of the exhibition will be a reproduction of the old "Nieuwmarkt," or New Market, and another an "electric restaurant" without waiters, in which visitors, by pressing an electric button, will be automatically served with a complete dinner.

KEIGHLEY.—The Town Council at their last meeting had under consideration a proposition that application should be made to the Board of Trade for a Provisional Order; but after some discussion the matter was referred back to the Committee, which, it was understood, is tantamount to shelving the question for another year.

LIVERPOOL.—The *Echo* derives cold comfort from the scheme submitted to the Watch Committee by the Liverpool city engineer, Mr. H. P. Boulnois, by which the ratepayers are to be saved the sum of £7,000 per annum. This is to be effected by curtailing the number of public gas lamps during the "burglar hours." In a city which in many things is progressive, this certainly appears a strange resolve, and it may be it is only the forerunner of an opposite policy, under which the electric light will be introduced to serve as an object lesson to the ratepayers. Mr. Charles Rettie is of opinion that the Liverpool municipal authorities must sooner or later—and the sooner the better—adopt the electric light, and ridicules the reasons given for postponing the matter.

LEEDS.—The new Medical School and the College Hall of the Yorkshire College at Leeds, opened on Friday last by the Duke

Digitized by Google

and Duchess of York, are lighted throughout by electricity, the entire installation having been carried out by Mr. T. Harding Churton, of Leeds.

METER TESTING.—The London County Council announce that they are now in a position to test electric light meters. Communications in respect to this matter must be addressed to the Engineer-in-Charge, London County Council Testing Station, 42, Cranbourn-street, W.C.

MILL LIGHTING.—The electric light has been fitted throughout Commercial Mill, Slaithwaite, near Huddersfield, the property of Messrs. Pearson Brothers, the work having been done by Mr. Holmes, of Huddersfield.

MONTROSE.—At a meeting of the Town Council on Monday, Mr. Whiteman moved that the Council support the Scottish House-to-House Electric Lighting Company (Limited) in applying for a Provisional Order to supply electric light to the burgh. A long discussion ensued, and an amendment moved that the matter be delayed until after November, but Mr. Whiteman's motion was carried by a large majority.

POPLAR (LONDON, E.).—The Poplar Board of Guardians have referred to a Committee a letter from the Poplar Board of Works, asking whether, in the event of the Board installing the electric light in the district, the Guardians would be prepared to take current for their offices and buildings for a stated period.

SOUTHPORT.—The Electricity Committee of the Town Council have resolved to illuminate the public buildings and fountains on the inauguration of the electric light on November 9th and 10th, and Councillor Boocock has given notice to move that the electric lighting of Lord-street and the Promenade be at once agreed to.

ST. BRIDE'S INSTITUTE.—This is the name given to a palatial building just erected as a home of technical instruction and physical relaxation for lads and young men engaged in the printing trades in the neighbourhood of Fleet-street, London. On Monday last the first of the technical printing classes was opened. The building is admirably adapted for the purpose, and is to be lighted throughout by electricity. A portion of the installation is already complete, the work being carried out by Messrs. Edmondsons, of George-street, Westminster.

WELLS.—At the last meeting of the Town Council a letter was read from the Gas Company with reference to the proposal of the Council to adopt the electric light in the city, in which the company asked the Council to let them know before taking any action to promote the introduction of the electric light. Some discussion ensued, and eventually the letter was referred to the Lighting Committee to act upon it as they thought best.

WHITECHAPEL (LONDON, E.).—At the meeting of the Whitechapel District Board of Works, last week, the report of the Streets Committee with regard to the scheme for lighting the district by electricity came up for discussion. Mr. Catmur, L.C.C., referred at some length to the three alternative schemes submitted in the report, and pointed out that the only resolution the Committee had passed was one in favour of a comprehensive scheme to light the whole parish, rather than a scheme to light only a portion. He moved that the report be received and adopted, and that the whole question be referred back to the Streets Committee for further consideration and report. The Committee would then recommend the adoption of one or other of the schemes, and that would bring the whole matter before the Board for consideration and discussion. The motion was carried unanimously.

WHITEHAVEN.—At the last meeting of the Trustees of the Town and Harbour of Whitehaven the Chairman laid before the Board some particulars with regard to the progress of the electric light financially for 12 months from September 2, 1893. The expenditure during that period for maintenance and sundry payments had been £1,213. 13s. 8d., and interest on capital had been £1,500. 13s. 4d. The revenue from the electric light was £744. 3s. 4d. The average cost for gas per annum for five years had been £909. 17s. 11d., but for exact comparison the cost must be added of 30 extra lamps which had been provided since electricity had been adopted. This would raise the average cost of gas to £984. Taking the actual sum, however, at £909, the profit on electric light for the year had been £103. 7s. 11d. The estimated working expenses of the station were £990, and the total annual expenditure £2,015. The receipts from the harbour for lighting were £220, and for private lighting, based upon actual present supply, the receipts equalled £1,028. 8s. 6d., making a total income from the harbour and private lighting of £1,248. 8s. 6d., and if they got £909. 17s. 8d. (which would be the cost for gas for the town) showed a profit of £143. 6s. 5d. per annum. It was absolutely necessary to provide two more dynamos, costing £1,479. Taking credit for the output of one more dynamo, and leaving the other dynamo for emergencies, this would give receipts amounting to £1,443. 16s. 6d., or a profit, charging public lighting as before for the last five years, of £232 per annum.

WOLVERHAMPTON.—A question was put at the meeting of the Town Council on Monday as to when the electric light installation would be finished. In reply, the Mayor said that the contractors were to have completed their work before September 18th last; but, owing to the carpenters' strike and other causes, they got behind. The work would, however, be finished in a few weeks.

WORTHING.—The Town Council on Tuesday adopted a recommendation of the Electric Lighting Committee that a consulting electrical engineer be instructed to furnish plans and information respecting the electric light installation.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

LATIMER CLARK, MUIRHEAD AND CO. (LIMITED).

Convened by the receiver and liquidator, Mr. James Worley, F.C.A., a meeting of the creditors of this Company took place yesterday (Thursday), at Winchester House, Old Broad-street.

Mr. WORLEY stated that there were about 250 persons who were returned as creditors of the Company, and that being the case, they would observe that there was only a very small attendance. He felt that he was placed in a very peculiar position. There was no obligation on his part to convene a meeting, but he had felt that it was the right course to take. Nor was there any obligation on his part to publish any statement of affairs; but naturally every creditor desired to have reliable information as to the position of the Company, and he had thought that the "shortest cut" would be to make up the books and to issue a statement, which he had accordingly done. Alhough he had called them together he had no proposal to make; but he was ready to give any further explanations that might be required respecting the transactions and the present position of the Company. He regretted extremely that he had felt obliged to say in his report that he saw no prospect of the unsecured creditors receiving any dividend. Against net liabilities put down at £81,697, the assets were returned only at £34,675, leaving a deficiency of about £47,000. There was no doubt, too, that when they came to wind up the estate they would find that the actual deficiency was even more than that, because the values put upon several of the principal assets were merely nominal—book values—and it would be impossible for anyone to say what they would produce until the actual realisation took place. Soon after his appointment as liquidator it became his duty to make a special report to the judge with respect to the issue of debentures, and they would agree with him that, so far as the unsecured creditors were concerned, this was a most important matter, because the claims under the debentures amounted to no less than £60,592; in other words, the debenture claims were so heavy that if the assets were even double what they were, the whole amount would be required to satisfy these claims. The debentures had been issued in regular order, and money was received for them, excepting an amount of about £5,700, representing debentures issued in part payment to the vendor for the original concession. The interest on the debentures had been allowed to accumulate for a considerable time. Many of these, no doubt, had naturally thought: Why did the Company keep on trading so long? Did they not know some time ago that they were insolvent? He might say that, so far as his investigations went, it would seem that the Company was never very flush of money, but there were gentlemen on the Board who possessed considerable means, and who appeared to have taken from time to time a very hopeful view of the prospects of the Company. Hence they were induced to make advances as required from time to time, and it seemed that so recently as last year they quite thought that the Company would be able to retrieve its position. Negotiations had been going on for some time for the reconstruction of the Company—the intention, he understood, being to take over that portion of the business which had been found to be profitable, and to abandon other work which had not been found profitable. It was thought that arrangements would be made on such a basis as would enable the old Company to pay all its creditors in full, and it seemed that the Directors were particularly anxious that something should be arranged on that basis, for the reason that they wanted to finish the contracts they had in hand. If these contracts had been stopped the result would have been even more disastrous than it was now. He was also told that they believed that when these contracts were finished there would be a fair profit to come to the Company; but, as frequently happened with contracts—particularly those with public bodies—when one got to the fag-end of them, claims were made, and requisitions were sent in, which altogether destroyed the reasonable expectations of profit accruing from the work. That, to a great extent, had been the case with this Company. When he was appointed to the dual capacity of receiver and liquidator of the Company, he found that there were several contracts which had to be finished, and he had no alternative but to complete them, because there were considerable sums due to the Company in connection with them. Having given particulars of the contracts in question, he stated that the terms were most oppressive. They were all in favour of the different authorities, and the risk run was considerable, and out of all proportion to the narrow margin of profit on which the estimates were made up. That, in fact, seemed to be "the order of the day." Firms took contracts with little or no margin of profit, and if anything went wrong there was a heavy loss at the end instead of a profit for the heavy responsibility which had been incurred. The heaviest contract of all was that connected with the electric lighting at Richmond. The Company undertook this work direct from the Corporation of Richmond, and then, about two years ago, arrangements were made for the formation of an independent company for taking it over. This was done, but this Company had to subscribe largely to the shares of the Company which took over the business. It was only recently that the contract had been completed. The prospects of the Richmond Company, so far as he had been able to gather, were fairly good, but at the moment they were not doing very well, and, like many other companies in the same position, they required additional capital. It was owing to the money that was locked up in these different contracts that the suspension of this Company last January was due. They could not get in the money owing to them, they were face to face with these contracts, and no course was open to them but to wind up the Company. So far as he could gather there was nothing at all to conceal. No doubt many grave mistakes had been made in the Company, but he had seen no reason to doubt the *bona fides* of those connected with it. The Directors themselves had embarked considerable sums in the Company, and he could not see that they had ever gained anything by it. They had not even had their interest, and, as regarded Directors' fees, for the last seven or eight years no such fees had been paid. It seemed that they had carried on the Company in the expectation that things would "take a turn," and in that case they would have surmounted their difficulties; but, unfortunately, things had gone the other way. No doubt their attention had been drawn to the form of the debenture. It was very comprehensive, and seemed to give the holders a first charge on the undertaking, and all its assets. At the date of the suspension the Company held shares in two or three other companies, to the amount of £16,000, and for this purpose he had taken these at their nominal value, but there did not seem to be any satisfactory market for them at the moment. The value of shares depended on the dividends that were paid on them, but in these cases no dividend had been paid.

In the course of the discussion which followed the action of the Directors was severely criticised. One creditor stated that he was "trapped" into £650 only two days before the failure.

Mr. WORLEY, in answer to questions, stated that the interest on the debentures was originally 5 per cent., and, latterly, 6 per cent., and on loans the interest was also 6 per cent. Quite four or five years' interest on the debentures was unpaid: in some cases seven years' interest was due. About £12,000 or £13,000 in cash was received under the Richmond Contract, but out of this they had to invest £6,000 in the shares of the Richmond Company. As regarded the issue of debentures for £25,000, Mr. E. Clapham, a Director, held £11,200; Dr. Muirhead £14,000, Mr. H. J. Muirhead £1,200, Mr. F. L. Muirhead £1,100, Mr. John Muirhead £3,200, Mr. Arnold Trinder £100, Mr. Latimer Clark £1,800, and Mr.

Digitized by Google

Douglas B. Hall £5,000. As regarded the second issue, Mr. Clapham held £2,800, Dr. Muirhead £400, Messrs. H. J. and F. L. Muirhead £4,000 jointly, Mr. H. J. Muirhead £200, Mr. F. L. Muirhead £300, Mr. John Muirhead £2,600, Mr. Clark £400, and Messrs. Trinder and Romer £400. A further sum of £12,000 had been issued to Mr. Clapham and others as security for advances and guarantees given to bankers. The Legislature had not imposed the duty on companies of publishing a balance-sheet. This Company was more in the nature of a private than a public company, and the former were generally the more successful. The debenture register was open to the creditors. He thought he ought to say that the bulk of the unsecured creditors seemed to be firms who had transactions with the Company for years; but there were a few creditors whose cases were hard.

Mr. F. DAWES said that if he was rightly informed Mr. Clapham believed in the concern up to the very last, and he was one of the largest unsecured creditors, if not the largest.

Mr. WORLEY replied that that was so.

Mr. HALL observed that he appeared to be the only Director present, and he could only say that he had been induced to put £5,000 into the concern.

Mr. SPENCER asked whether Mr. Hall, in his capacity of a Director, received a financial statement.

Mr. HALL replied that periodically there was a balance-sheet.

Mr. SPENCER: Was it certified by any you could rely on?

Mr. HALL: I do not know.

Mr. WORLEY, in further reply, said that Mr. Clapham's advances amounted altogether to £24,000, and the trade creditors had had the benefit of all the money which this gentleman had put into the undertaking.

On the motion of Mr. SPENCER, a vote of thanks was passed to Mr. Worley, and the meeting then separated.

NEW COMPANIES, STATUTORY RETURNS, &c.

"LA BOITE MAGIQUE" (LIMITED).—This Company was registered on September 27th, with a nominal capital of £3,000, in 2,500 Preferred and 500 Deferred shares of £1 each, to carry on (*inter alia*) the business of electricians, electrical and mechanical engineers, and manufacturers of and dealers in all electrical apparatus.

T. AND R. BOOTE (LIMITED).—This Company was registered on September 29th, with a capital of £50,000, in £10 shares, to carry on the business of manufacturers of and dealers in electrical appliances and apparatus, carried on at Burslem, Staffs.

BOWES-SCOTT AND WESTERN (LIMITED).—This Company was registered on October 5th with a capital of £10,000 in £1 shares, to acquire the business of Bowes-Scott and Western, mechanical engineers, of Westminster, and to carry on the business of iron founders, mechanical engineers, manufacturers of mining implements and other machinery, tool makers, brass founders, metal workers, boiler makers, millwrights, electrical engineers, &c.

ROBERT HALL AND SONS, BURY (LIMITED).—This Company was registered on October 4th, with a capital of £75,000 in £10 shares, to acquire the business of Robert Hall and Sons, Bury and Manchester, and to carry on the business of manufacturers of and dealers in textile machinery and apparatus, mechanical engineers, metal workers, tool makers, millwrights, electrical engineers, &c.

LLANBERIS WATER AND GAS COMPANY (LIMITED).—This Company was registered on October 4th with a capital of £5,000 in £1 shares, and, as is now usual with provincial gas companies, includes among its objects the establishment, working and maintenance of electric light works for the supply of light to the parish of Llanberis, in the county of Carnarvon.

DIXON AND CORBETT AND R. S. NEWALL AND COMPANY (LIMITED).—The annual return of this Company, made up to August 22nd, has been filed. 6,000 Ordinary and 1,957 Preference shares have been taken up. out of a nominal capital of £120,000, in 6,000 Ordinary and 6,000 £5 per Cent. Preference shares of £10 each. All the Ordinary and 250 Preference shares have been issued as fully paid, while £13,648 has been received in respect of a call of £8 per share on 1,707 Preference shares, leaving £8 in arrears.

EXETER ELECTRIC LIGHT COMPANY.—The annual return of this Company made up to June 26th, has just been filed. The nominal capital of £20,000 is divided into 1,500 Ordinary and 500 "A or £6 per Cent. Preference shares of £10 each; 1,125 of the former and 73 of the latter have been taken up, and 305 Ordinary have been issued as fully paid. The full amount has been called on 820 Ordinary and 58 Preference shares, and £1 per share on the remaining 15 "A" shares, resulting in the total payment of £8,795.

FORD-LLOYD MANUFACTURING COMPANY (LIMITED)—The first annual return of this Company, made up to August 30th, has been filed. 4,707 shares of £1 each have been allotted, out of a capital of £10,000, in £1 shares, and 4,000 of these have been issued as fully paid, while the full amount has been called and paid on the remaining 707 shares.

IMMISCH ELECTRIC LAUNCH COMPANY (LIMITED).—The statutory return of this concern, made up to August 11th, has just been filed. The nominal capital is £12,000, in 10,000 Ordinary and 2,000 £8 per cent. Cumulative Preference shares of £1 each. 8,965 Ordinary and 1,507 Preference shares have been taken up, of which all the former have been issued as fully paid to the General Electric Power and Traction Company (Limited), of Queen street-chambers, London, E.C. Upon the Preference shares a call of 5s. per share has been made, resulting in the payment of £301, and leaving £75. 15s. in arrears.

SAYCEE ELECTRICAL SYNDICATE (LIMITED).—An agreement, dated September 18th, between William H. Longsdorf (the vendor), George M. Gordon (the trustee), and the Company, states that, whereas, by an agreement dated August 16, 1894, the vendor agreed to transfer to the Company certain inventions and patent rights relating to "improvements in primary batteries," in consideration for fully-paid shares, it is, therefore, agreed that the Company shall take over the provisions of that agreement, and allot 6,000 fully-paid Ordinary shares and 500 Deferred shares to the vendor, in full satisfaction for the said transfer of patents.

WALSALL ELECTRICAL COMPANY (LIMITED).—The first annual return of this Company, made up to September 13th, has been filed. Out of a nominal capital of £10,000 in £10 shares, 683 have been taken up, of which 200 were issued as fully paid to Frederick Brown, electrical engineer, of Highgate-road, Walsall (the vendor); upon each of the other shares the full amount has been called and paid.

CITY NOTES.

ALUMINIUM COMPANY (LIMITED).—Mr. G. W. Balfour presided over a meeting of shareholders in this Company, at Cannon-street Hotel, on Wednesday, and said that at the last meeting he placed before the shareholders certain anticipations as to the profits likely to be made, and he was pleased to say these anticipations had practically been verified. He had estimated a profit of about £25,000, whereas the actual profit made was between £19,000 and £20,000. This profit, after the payment of all proper charges, depreciation, &c., enabled the Directors to declare a dividend of 5 per cent. on the A shares, absorbing £3,000, and to carry forward £1,475 to next account. During the past year their sodium business had been maintained, and steps had been taken to cheapen the manufacture, and their efforts with the caustic process had been entirely successful. With regard to the name of the Company he pointed out that this was a misnomer, as they no longer continued the manufacture of aluminium.

BIRMINGHAM CENTRAL TRAMWAYS COMPANY (LIMITED)—At the meeting of this Company, held at Birmingham on Wednesday, the proposal to reduce the capital from £500,000 to £300,000, was carried unanimously.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The accounts of this Company, subject to audit, show a profit, which justifies the Directors in recommending a final dividend of 3s. per share, making with previous distributions a total dividend of 6 per cent. for the year ended June 30th last, and also the payment of a bonus of 1s. per share (both free of income tax), which together will amount to £26,000, leaving a balance of £16,501, of which amount £15,000 has been placed to the reserve fund and £1,501 carried forward. These payments will be made on and after the 25th inst. The register of transfers will be closed from the 16th to the 24th inst. inclusive.

CENTRAL CHILI COPPER COMPANY (LIMITED).—Sir John Pender G.C.M.G., M.P., presided on Wednesday over the statutory meeting of the above Company, which was formed some time back to take over the Panulcillo Copper Company, with which the Chairman had been for so many years associated. He said that he had seen the old Company in considerable prosperity and in very great adversity. More than once he had been called upon to lift the concern out of adversity into prosperity. He had himself subscribed, and was the largest shareholder in the new Company in the honest belief that better times were in store for them. The time had expired when shareholders of the old Company might become shareholders in the new, but the Directors were willing to extend this period to the 20th inst. They did not anticipate any difficulty in placing the shares, and over 300 out of the 500 shareholders in the old Company had taken up a financial interest in the new enterprise. He hoped to be able at a future date to announce a dividend. Mr. Collins, one of the Directors of the new Company, expressed his belief in its prospects.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended October 7th, were £892, as against £816 in the corresponding period of 1893, being an increase of £76. The total receipts for the half-year amount to £12,011, as against £11,295 for the corresponding period of 1893, an increase of £716.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—The revenue return of this Company for the quarter ended September 30, 1894, is as follows:—Sale of current for public lighting, £3,141. 19s. 2d., against £3,027. 10s. 9d., in the corresponding period of 1893; private lighting, &c., £7,676. 14s. 9d., against £3,551. 15s.; other sources, £416. 12s. 5d., against £441. 12s. 11d.—total, £11,235. 6s. 4d., against £7,020. 18s. 8d., increase of £4,214. 7s. 8d. The equivalent of 8-c.p. lamps connected on September 30, 1894, was 114,031, against 53,445 in September 30, 1893.

ENGINEERING AND GENERAL CONTRACT CORPORATION.—The poll demanded by the Directors of this Company has resulted in the acceptance of the Directors' report and accounts, and the rejection of the report presented by the Committee of Investigation.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for the month of September, 1894, amount to £25,200, and from January 1st to September 30, 1894, £207,400. In the corresponding months of 1892 and 1893 the amounts were £199,600 and £203,600 respectively.

SUBMARINE CABLES TRUST.—Notice is given that on and after the 15th inst. the sum of £1. 15s., on account of the coupon due October 15th, will be paid by Messrs. Glyn, Mills and Co., of 67, Lombard-street, between the hours of ten a.m. and two p.m. Coupons must be left with the bankers for examination four clear days before payment.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended October 5th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £3,186.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 857.—Vol. XXXIII. FRIDAY, OCTOBER 19, 1894. PRICE FOURPENCE. *Annual Subscription (U.K.), 19/6*

NOTES.

An impartial and thorough discussion of the problem of replacing factory gearing by electric motors, by one who is practically conversant with this class of work and has had many years of experience in the running of an engineering works, should be welcomed by everyone who is desirous of seeing the matter placed on a sound practical footing. Mr. Thomas Richardson, in his Presidential address delivered before the North-East Coast Institution of Engineers and Shipbuilders, an abstract of which we publish this week, attacks the problem from this standpoint; and it is gratifying to find that he can speak so favourably of the transmission of power by electric current in factories and mills. In reading Mr. Richardson's address the conviction is forced on us that we are listening to no mere enthusiast, but to a man who is carefully weighing the *pros* and *cons* of the question. "Particulars such as these," he says, referring to the examples he has cited, "are always of general interest, but any radical change made in existing works involves a very considerable outlay, and extreme care is necessary to be certain that such a change would be commercially successful."

Disregarding those people who look unfavourably on the use of electromotors in any form or shape, the opinions of experts may be divided into two classes: firstly, that the utmost subdivision of the power should be carried out, each machine tool or separate plant having its own electromotor; secondly, that the power should be electrically subdivided only between the various shops, and that a single electromotor in each shop should drive the machines in that shop by ordinary belts and countershafts. On the one hand we have only half measures, on the other whole measures; but cases are conceivable where half measures would be the better of the two.

Speaking broadly, it is probable that the half measure is the more suited to existing shops or works, while the more thorough system might more economically be adopted in cases where an entirely new shop or works is to be erected. To alter every machine in a large shop, so as to enable it to be economically driven by its own electromotor, would swallow up such a large capital sum as might entirely spoil the value of the change; for the mere cost of the electrical plant would be small compared with the cost of removing the old gears and properly adapting the new. On the other hand, where an entirely new set of plant is to be erected in an entirely new building, the adoption of the whole measure has the advantages that the cost of countershafting and belting is entirely saved, and the structure in which the machines are to be placed may be made much lighter and cheaper in construction, owing to the absence of the weight and stress of the gears from the walls and columns. To engineers, however, it is unnecessary to say that each particular case must be judged according to its individual conditions; for it is very probable that many existing works might be more profitably fitted on the complete system than on the alternative plan of putting only one motor in each shop. Useful provision for this class of work is being made by more than one machine-tool manufacturing company, the electromotor being built on and adapted to the machine in such a manner as to make a most compact, handy, and efficient plant. For, indeed, whatever may be said as to the exigencies of the problem, there can be no doubt that the ideal system is one in which a corporate part of each machine is the motor which drives it, and the switch which regulates it; or, in the case of very complicated machines, there might even be more than one motor incorporated with each separate plant.

It may have been a great thing to stand on a tight-rope over Niagara Falls and cook an omelette the while; but it had been an infinitely greater thing for the acrobat to have made the Falls cook the omelette. At the banquet in celebration of the opening of the Worcester electric supply station, several of the "viands" were cooked by means of a waterfall at a distance of about three miles from the banquet hall. Of course, there is nothing really wonderful in this achievement. Nothing is wonderful when it has been explained, and any "second year student" could explain how water power may be used for electric cooking. The Worcester Corporation is doing its best to find work for its turbines and dynamos during the daytime; for not only has it thus advertised the usefulness of the electric current for heating and cooking, but it has also found actual work for the electric power at some of the Corporation works, notably at the waterworks. Worcester, too, is a town in which there are a number of various manufactories, almost every one of which requires highly-subdivided power during the daytime; and this class of power can be much more conveniently supplied by means of a number of small electric motors than by means of a single large steam engine. Altogether, the prospects of an even and fairly large day load are better at Worcester than at the average district under electric supply.

Digitized by Google

A few more circulars such as that just issued by the Isle of Man Electric Tramway Company, and the forthcoming discussion on Mr. Wilkinson's Institution Paper on American electric tramway practice will fall through for lack of debaters; they will all be engaged in advising town councillors, drawing up reports, drafting prospectuses, and estimating *in futuro* dividends, being themselves divided between the advisability of figuring out an attractive 10 per cent. or a modest 5 per cent. per annum. The circular in question states that the Directors of the Company, having carefully considered the profits for the past season, and having consulted with the auditors, are enabled, after providing a large sum for the reserve and renewal fund, and making provision for further dividends at the end of the year, to pay an interim dividend at the rate of 7½ per cent. per annum on the Ordinary shares for the six months ending October 31st. If only it were possible to do likewise in South London!

Although the Welsbach gas burner has proved a formidable rival of electric lighting in Germany and in one or two places in this country where active agents have taken it up, it is probable that the gas companies rather than the electric supply companies will suffer from the renewed efforts which are being made to popularise it. The Incandescent Gas Light Company may well be proud that, in spite of its many disadvantages, their burner, when it is in order, is the most economical means of producing light from gas, or probably from any other artificial source. The latest circulars announce the price of the cheapest burner at 15s., the mantles at 1s. 10d. to 1s. 3d., and the annual cost of keeping a burner in order at 4s. to 5s., "or even less if the user is willing to look after the light himself." The consumption is given at 3¼ to 3¾ cubic feet of gas for "about 50 to 60 candle-power." Those who do not want 50 or 60 candle power will do well to buy a thick shade, and cut down the light to a reasonable amount, or to wait for a week or two until the candle-power falls off of its own accord, as it readily does. Attempts are made to disguise the Bunsen burner and stem and the long chimney by all sorts of shades and globes, but the inevitable ugliness of shape is realised at once when an attempt is made to fit one of these burners on a handsome wrought-iron gas fitting. One of the distinct advantages of electric lighting, which it is impossible to estimate in money value, is the convenience of switching on or off without having to hunt for matches; but with a Welsbach burner a spirit lamp or electric lighter is recommended. The one is, of course, generally empty, and the other almost invariably out of order; but, of course, such trifles are no obstacle to the publishing of startling comparisons between costs of lighting by this bilious-looking contrivance and by electric glow lamps.

The "average man," like everyone else in this world, has his uses, and when he happens to be a consumer of electric energy, it seems to us that his usefulness is of a very high order, and for this reason: He is absolutely proof against the angry eloquence of the advocates of this or that electrical nostrum. He cares not whether the current comes to his lamps *via* two, three or five wires, provided he gets it. So long as his filaments steadily glow, they may be traversed, for aught he cares, by true sine curves, battered tall hat curves, or blunted saw-tooth curves. He is absolutely indifferent whether alternators are run in parallel or on separate circuits, though he has a decided aversion to a throbbing and bobbing light, like unto the uneasy motion of a storm-tossed sea. The virtues or vices, merits or demerits, of water-tube *v.* Lancashire boilers, double *v.* single-acting engines, direct *v.* rope driving, high-speed *v.* slow-speed running, india-rubber *v.* paper insulation, are beyond his province. He only asks for light. And his usefulness lies in the very simplicity of his demand. Emphasised by threats to "go back to gas" or "to write to the papers," it brings home to us the elementary fact that the whole duty of an electric supply station is to give its customers day after day, year in and year out, all the current they desire at the pressure their lamps require. The difficulties of providing a continuous supply of electrical energy at a constant pressure are, owing to the lack of storage capacity, far greater than is the case where gas is concerned. No one, however, is under compulsion to supply electric current; but the obligation once entered into, he is under statutory compulsion to fulfil the contract. And, as a measure of this fulfilment, it is sheer waste of arithmetical brain-power to express the few odd moments during which the light is out as a percentage of the time it is not out. There, again, our faithful friend, the "average man," comes to the rescue with the painfully unscientific retort that the failure which left his dinner-table in the gloaming is not compensated for by the fact that the light is always there to assist Buttons in cleaning the boots of a winter's morning. These are truisms, we know well; but an impression which has gained strength of late, that central stations are principally intended to illustrate the glorious uncertainty of all things human, was thought to need a decisive negative.

Cable Interruption:	Date of Interruption.
Zanzibar-Mombasa	September 4, 1894.
Macao-Hong Kong	September 25, 1894.

University College of North Wales.—The calendar for the year 1894-95 is just issued, and contains full details of the educational courses at the University, which now include a day training college for men and women for training as elementary teachers.

Electrical Utilisation of Water Power.—A company has just been formed in Zurich with a capital of £30,000, to be known as the Electricitätswerk Rathausen. It is proposed to establish a central station near Rathausen, where water power to the extent of 1,200 H.P. will be utilised.

Physical Society.—The first meeting of this Society will take place on October 26th, at 5 p.m., at the rooms of the Chemical Society, Burlington House. A Paper "On the Thermal Constants of Aniline" will be read by Mr. Griffiths, and Mr. Naber's voltameter will be on view.

Lightning on an Underground Cable.—The cable running through the St. Gothard tunnel from Airolo to Goeschenen was recently severely damaged by lightning. This unusual occurrence of lightning injuring such a cable is attributed to the bad earth made by a lightning guard (?) common to the cable line and to the overhead line leading up to it.

Aluminium.—The Aluminium Manufacturing Company of Neuhausen is now turning out three tons of aluminium a day, and the selling price has come down to 3 marks 20 pfennigs,

Digitized by Google

say, three shillings per kilogramme, or about 16 pence per pound. This is a long way from the promised twopence per pound; but, remembering that the bulk of aluminium is 3 times that of copper, for equal weights, the cost of aluminium is only 33 per cent. greater than copper, for equal bulks.

The Indo-Chinese Telegraph Line.—The connection between the India and Chinese telegraph systems will be made from Nampoung to Momein, the distance between these two places being between 60 and 70 miles only. The alignment, says the *Indian Engineer*, will thus be along the valley of the Taeping River, which is the caravan route for trade between Burma and Yunan. The posts and wire for the whole of the new line will be sent from India to Bhamo and thence onward to Nampoung, where work will be begun.

Cheltenham.—We hear from a correspondent that the Corporation are pushing ahead with the laying of mains in the principal streets, and that the station and plant are well in hand. It is doubtful, however, if the current will be available before December 1st. The light is being pushed very hard in the town by contractors, and the competition in wiring, &c., will be extremely keen, eight local firms having taken up electric lighting, and several engineers from other towns are contemplating opening branches there. We may add that the capacity of the station is only about 5,000 8-c.p. lamps fixed.

Telegraph Statistics.—In 1870 the number of telegrams transmitted in the United Kingdom was 9,350,000; in 1892 the total had risen to no less than 69,908,000. The Americans received and despatched 9,157,646 telegrams in 1870; in 1892 (notwithstanding the enormous increase in the population of United States during the 22 intervening years) the corresponding total did not exceed 62,387,298. France ranked third among telegraphing countries in 1891, her telegraphic movement in that year comprising 32,397,000 messages. Germany comes fourth, her latest annual telegraphic budget exhibiting an aggregate of 31,175,100 telegrams. Austria ranks fifth, but cannot muster a larger aggregate than 10,835,302 despatches. Italy is sixth, with 8,322,925.

The French Telegraphs.—M. Maurice Faure, in the recent discussion of the telegraph estimates by the Budget Committee, animadverted on the practice of communicating private telegrams to Government departments, and urged that this should only be done in the case of telegrams of interest to the State. The *Temps* points out that the abuse is much more extensive. "Telegraph clerks frequently divulge messages to their acquaintances, so that a whole village is informed of the contents of a telegram even before it reaches the recipient." Prefects, moreover, make copies of all messages, and "in Paris the duplicates sent to the Ministry of the Interior afford much amusement to the clerks." Expensive telegrams from distant countries to the *Temps* have been communicated to other newspapers on friendly terms with telegraph clerks. The *Temps* might have added that in Paris every telegram addressed to, or sent by any prominent man is communicated to the President and six or seven of the Ministers. It may be remembered that during the crisis of 1877 the Paris newspapers in this way professed to quote from *The Times* a telegram which, though sent to it, had not been published by it.

Horse Racing by Electric Light.—The racecourse at Maspeth, Long Island, belonging to the Newtown Jockey Club, has been lighted by electricity, and is the second American course where the electric light has been introduced, the first being that at St. Louis. The novelty is reported to have proved a complete success. The Maspeth racecourse is half a mile long, and closed in by a high fence of white board. The track is lighted at night by clusters of glow lamps suspended over the middle of the course, the light being thrown down by reflectors. The horses as they run round are followed by powerful search lights. Arc and glow lamps light up the grounds and grand stand. The electric plant includes two 115 H.P. engines, and two Edison 100-kilowatt generators. There are 200 clusters of four 32-c.p. lamps each over the track, 100 32-c.p. lamps distributed about the entrances, betting ring, offices, &c., 50 16-c.p. lamps, 28 arc lamps, and three 6,000-c.p. search lights. During the race the load is 1,050 amperes at 135 volts. The track is wired in three sections, and these sections in turn are wired so that, if one machine were to break down, alternate clusters of lamps would burn, so that the chances of the course being thrown into total darkness are very remote.

Areas of Circles.—The area of a circle = diameter squared × ·7854. To facilitate the calculation, Mr. J. Macfarlane Gray many years ago published the following remarkable rule for multiplying by 0·7854:—Multiply by ·7, repeat, double, repeat; writing each successive product one place to the right.

```
·7    = 1 × ·7
 7    = repeat
 14   = double
  14  = repeat
─────────────────
·7854 = 1 × ·7854
```

or again:—

```
432
 ·7
───
302·4
 30·24
  6·048
  ·6048
──────
339·2928 = 432 × ·7854
```

The M'Evoy Submarine Detector.—It is now a little over a year since the Russian monitor "Rusalka" foundered with all hands in a storm in the Gulf of Finland. Steps were subsequently taken by the Russian Government to discover the precise locality of the ill-fated vessel. The expedition consisted of a flotilla of several vessels, equipped with divers and all necessary apparatus, including one of Capt. M'Evoy's submarine detectors, which was specially made for the purpose. The precise position has now been localised in 30 fathoms of water by means of the submarine detector, a brief description of which has appeared in our columns. The apparatus is based on the principle of Prof. Hughes's induction balance. There are two primary coils and two secondary coils, one pair being on deck, the other in the sinker which is trailed along the bottom. The two primaries are in series, and are traversed by an intermittent current, the two secondaries are in opposition. Before being used the apparatus is adjusted so that under ordinary circumstances little or no sound is heard in a telephone placed in the secondary circuit. Three hundred feet of electrical cable were employed with the detector in searching for the "Rusalka," and the depths searched varied from 15 to 50 fathoms. The search was continued for several weeks, and the exact position of the foundered vessel was at length placed beyond all question, as every time the searching steamer passed over a given spot the electric indicator of the detector sounded loudly, thus affording evidence that a large mass of iron was submerged below. After the vessel had been located the divers descended and examined her. Although most appropriate for the purpose of searching for wrecks of iron ships, the submarine detector was not primarily designed by Capt. M'Evoy with that sole view. His main object was to provide a means of indicating the approach of iron ships to anchored torpedoes, as well as of searching for stray torpedoes, lost anchors and chains, telegraph cables, and the like. The approach of a mass of iron, such as an enemy's ironclad, to the torpedo disturbs the balance and causes the sounds to become audible in the telephone. The torpedo may then be fired electrically by means of the cable connection, the invention thus presenting itself as an important adjunct of coast defence.

Light Railways.—An interesting example of the manner in which light railways may be successfully equipped and managed is, says *Engineering*, afforded by a line of this character which has been at work for two years in the department of Loiret, in France. It has termini 22 kilometres apart, at Pithiviers and Toury, both of which are stations of existing railways. The Conseil Général, or County Council, decided to construct the line out of their own funds, primarily for the development of the beetroot industry, and also because it promised to save the roads by transferring part of the heavier traffic to the railway. After construction the line was leased to contractors, an

Digitized by Google

arrangement being made that the department should contribute half the difference when the receipts fell below a certain minimum, the Company, on the other hand, to pay over half the excess of receipts above a specified maximum. The line essentially differs from the railways of this country. It is laid at one side of the highway, without any kind of separation from the rest of the road reserved for cart and carriage traffic. But though thus similar to, it is different from steam tramways, for the rails are of the ordinary railway pattern, laid on steel sleepers and ballasted. The gauge is only 2ft. One great advantage of this narrow gauge and the portable permanent way adopted, is that farmers and others can readily lay down a temporary siding, which can be easily moved about to any field or barn where there are a few loads to be picked up, an advantage which has been largely realised. The passenger carriages are of the tramway type, and the waggons for goods are constructed to carry 10 tons each. Stations are represented by a weighing machine and a small office to hold parcels. Tickets to passengers are issued on the train by the guard, so that the working staff is small. The cost of building and equipping the line was £1,555 per mile, and it appears to have rendered nearly all the services to the district which a line costing £10,000 a mile could have afforded. Last year it carried 27,225 passengers, and during the beetroot season it carried in two months over 15,000 tons of beetroot—a smaller quantity than will probably form the average, the crop being a very poor one. The department had to pay the contractors a small sum last year, but they hope in a few years to realise 4 or 5 per cent. on their small outlay.

Engineering as a Learned Profession.—It is not so long ago that the claim of the engineer to be considered a professional man received, says *Engineering*, but a grudging assent, and that he was treated merely as a superior kind of mechanic. That time is now past, but even at the present day the public does not exactly class his calling among the "learned professions." The lawyer, the divine, and the doctor all stand on assured ground in the public imagination, but the engineer comes under a different classification. This results, we take it, from the scant literature associated with the science of engineering. Every clergyman is supposed to have a study filled with the "Fathers," and other ponderous tomes, and it is imagined that the greater part of the time is spent in that apartment in the perusal of erudite works, both ancient and modern. The lawyer brings his books into court with him, and sometimes the benches are completely covered with records of cases and expositions of principles. Whole libraries are composed entirely of legal works, and grow daily larger with the reports of voluminous judgments, incomprehensible to the lay mind. The doctor, too, has his books, and if these are not so large and numerous, they are still more difficult of comprehension than those of the lawyer. But the public knows nothing of the engineer's books. They look upon him, if he be more than a manufacturer, as a kind of genius who arrives at his results by inspiration, aided by a certain amount of mathematics. They regard his abilities as something that he was born into, like the colour of his hair or the size of his feet, and while they admire the results of his work, they do not feel that he deserves any special personal reverence. The engineer suffers, too, in the popular esteem, as compared with the members of older callings, in having no professional manner. He is too like other men to strike the popular fancy. The judge on the bench, even the family solicitor in his office, is something above and apart from ordinary humanity. The parson never forgets his calling, and seldom discards his uniform. The doctor, although often a jolly good fellow away from home, cannot afford to gain a reputation for levity in his own district; an imposing deportment is of more use to him in securing patients than the closest study. And so it follows that all these men are called "learned." They have their books, and they never let anyone find out how much—or how little—they know of them. Their demeanour is a coat of mail against the shafts of curiosity, and they are judged by the ponderousness of their armour.

The Minimum Current Audible in the Telephone.—In a Paper read before the British Association at Oxford, and published in the *Philosophical Magazine* for September, Lord Rayleigh states that the estimates which have been put forward of the minimum current perceptible in the Bell telephone vary largely. Mr. Preece gives 6×10^{-13} ampere; Prof. Tait, for a current reversed 500 times per second, 2×10^{-12} ampere; De la Rue gives 1×10^{-8} ampere; Prof. Ferraris, 5×10^{-9} ampere for a frequency of 514. The telephones employed by Lord Rayleigh in his experiments were two, of which one (T_1) was of 70 ohms, and the other (T_2) of ·8 ohm. In order to keep clear of complications due to self-induction, in the earlier experiments a resistance coil of 100,000 ohms, constructed, as usual, of wire doubled upon itself was employed. But it was found that the sound was nearly as loud when the 100,000 ohms was included as when a 10,000-ohm coil was substituted for it. Inquiry showed that the anomaly was due to condenser action of the doubled wire. To obtain electromotive forces of the necessary harmonic type a magnet revolving in the proximity of an inductor-coil was used. The magnet used was of clock-spring, about 2½cm. long, bent so as to be driven directly windmill fashion from an organ bellows. The coil used in most of the experiments was the one employed as the "suspended coil" in Lord Rayleigh's determination of the electro-chemical equivalent of silver; it is wound on an ebonite ring, has 242 convolutions, 10½ ohms resistance, and a mean radius of 10·25cm. When the magnet was driven full speed a frequency of 307 was obtained. To extend the determinations to higher frequencies, recourse was had to magnetised tuning-forks. In making the observations the current from the inductor-coil was led to a distance by leads of doubled wire, and was there connected to the telephone and resistances. Among the latter was a plumbago resistance of about 84,000 ohms; but in most of the experiments a resistance-box going up to 10,000 ohms was employed. The attempt to hit off the least possible sound was found to be very fatiguing and unsatisfactory; and in all the results recorded the sounds were adjusted so as to be *easily* audible after attention for a few seconds. Experiment showed that the resistance could then be *doubled* without losing the sound, although perhaps it would not be caught at once by an unprepared ear. It would appear as a net result that the maximum sensitiveness to current occurs in the region of frequency 640, the current in telephone T_1 being then $4{\cdot}4 \times 10^{-8}$ ampere; but observations at still higher frequencies would, Lord Rayleigh adds, be needed to establish this conclusion beyond doubt. Attention must be paid to the fact that the sounds were not the least that could be heard, and that before a comparison is made with the numbers given by other experimenters there should be a division by two, if not by three. Lord Rayleigh concludes by pointing out that measurements with the electro-dynamometer have been made by Cross and Page of the currents used in practical telephony. The currents found were of the order 2×10^{-4} amperes.——In this connection Carl Barus points out in the October number of the *American Journal of Science* that the alleged extreme sensitiveness of the telephone warrants one in replacing the galvanometer in a shunted circuit for the measurement of electromotive force (zero method) by the telephone. Devising a special key for the purpose, he made the test, but did not find the extreme sensitiveness stated. Even in specially-wound telephones of 6,000 turns of wire, the best result he could obtain was an audibility of 10^{-7} ampere, under the following remarkable conditions:—For increments of current amounting to $3{\cdot}1 \times 10^{-7}$ on either side of zero, the telephone did not respond at all. On both margins of this silent field, however, the response came in a way to make further increments of only 10^{-7} ampere quite distinguishable in loudness. Here, therefore, says the author, is a true discontinuity, for the extent of the interval of silence is at least five times the sensitiveness of the telephone on and beyond the margins of this interval. In the great variety of experiments made this result was the invariable feature, the silent interval being in some cases even 10 or 20 times the marginal sensitiveness. He interprets this to mean that the diaphragm of a telephone when in a state of rest initially resists deformation with a kind of molecular *quiescent friction*; and that this inertness must first be overcome by the actuating field before the diaphragm responds nicely to fine gradations of stress.

ELECTRIC MOTIVE POWER.*

BY ALBION T. SNELL.

(*Concluded from page 688.*)

While mentioning the subject of weight it may be remarked that if it be desirable to limit the weight of a coal cutter to, say, 10cwt., which is about as much as *one* man can shift about a pit with the aid of crowbars, it may be worth while to pay special regard to the making of a light machine. But if it be necessary from any cause, such as the need for a machine of greater capacity, to increase the dead weight much beyond the limit just mentioned, then it appears to the author to be a matter of little importance whether the machine weighs 20cwt., 30cwt., or even 40cwt. In either case it is too heavy to be handled without special tools, and a screw jack is as much a part of its equipment as it is of a locomotive's. In fact, with the larger type of electric machines the increase of weight is by no means an unmixed evil, for it gives increased stability, and no matter how rough the road, or uneven the dirt, the machine rides steadily through it all.

A side-wheel coal-cutter designed by the author and Mr. Major Waterhouse, of Glass Houghton Collieries, about four years ago is shown in Figs. 125, 126, and 127, which are plan, longitudinal, and end views. Much detail is left out in order to show up the main features. It will be noticed that the design roughly resembles that of the Yorkshire Engine Company's compressed air machine. But, in fact, the whole of the details have been modified to suit the increased rate of speed and to accommodate the gearing. The machine was built to hole 3ft. 6in. in a seam 34in. in height, on a *level* with the floor, this being the first machine so designed. The maximum height above the rails was 22in. The cutter made from 80 to 100 revolutions per minute in various kinds of shale and coal, no difficulty being found from their hardness or even from iron pyrites. The weight was about 35cwt. At least two men were found to be necessary to work the machine, and in soft coal with a rapid feed a third was required to keep the wheel from being fouled by the coal. The wheel was designed to run in either direction, but the inventors always arranged the cutters to feed the cuttings out at the back of the machine instead of the front, as is frequently done in air machines. It was found, however, that the wheel did not sufficiently clear itself, and that a man was required to shovel out the loose coal at the front from time to time. The power absorbed did not vary so much as was expected. The automatic feed, actuated by a worm and wheel from the first cross shaft, nicely adjusted the speed of the machine to the resistance of the cut. The motor was wound in simple series, and thus the current varied in proportion to the torque. And, since the pressure decreased slightly as the load increased, the tendency was to equalise the power absorbed and to vary the rate of feed with the degree of resistance to the cutters.

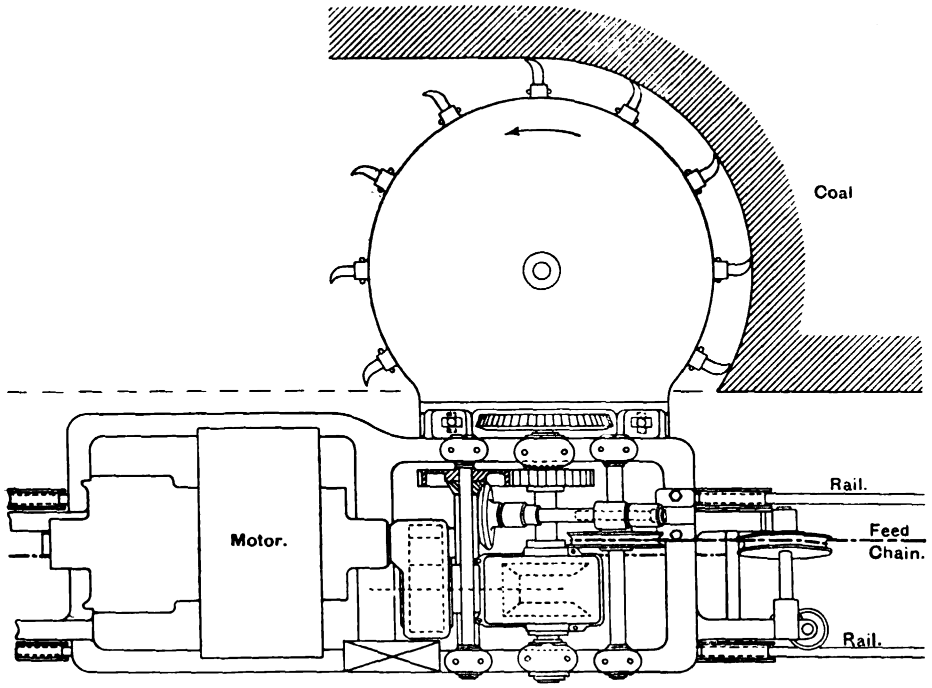

Fig. 125.—Snell-Waterhouse Coal Cutter. Plan.

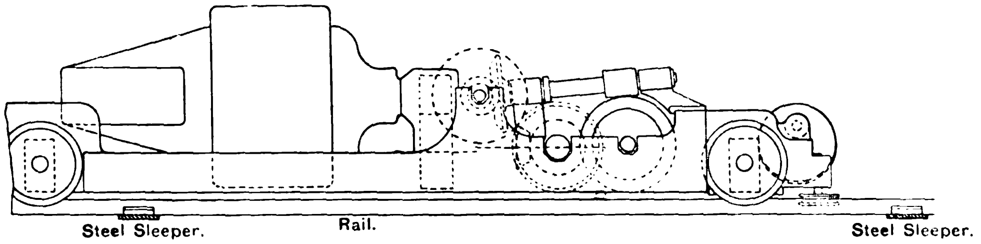

Fig. 126.—Snell-Waterhouse Coal Cutter. Longitudinal View.

The advantage of the wheel machine compared with the rotary bar lies in the low head room required, and perhaps in the enormous capacity of the wheel on long walls where the conditions are favourable. The writer, however, has never come across a machine which had anything like a chance of working continuously, and so reaching the theoretical output. This must necessarily be the case in the majority of pits, and the most useful machine is that which under the given conditions of normal working will give the largest average output, and not a maximum output for a short time under the best conditions.

The chief difficulties met with at Glass Houghton were due to the peculiar formation of the seam, which is 22in. in height

* All rights of reproduction reserved.

Digitized by Google

with a thin parting near the middle. The holeing was made on the level of the floor in the fireclay, and presented no serious difficulty. But the lower coal broke away from the parting, leaving the tops in position, and frequently fouled the wheel before a cut could be made sufficiently long for the introduction of wedges. Under these conditions the time wasted in clearing the wheel more than counterbalanced any gain from the high rate of speed at which the machine holed when the coal remained firmly in position. A bar cutter might have succeeded here if more head room had been permissible, for it is obvious that the fall of coal behind the bar or even on the top of it would not be so serious as with a side wheel. But in this case the large number of iron balls in the clay were held to be an obstacle in the way of the bar cutter, and, in addition, the bar could not be made to cut *perfectly* level with the flooring as was desirable. The power absorbed varied from 10 to

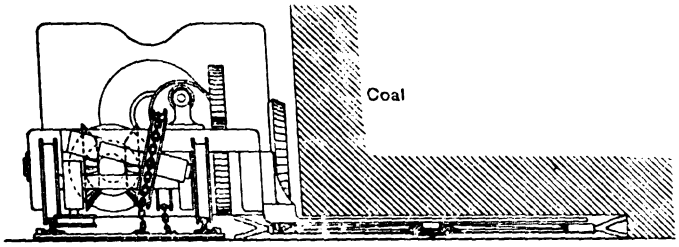

Fig. 127.—Snell-Waterhouse Coal Cutter. End View.

17 E.H.P. The motor was designed to give 15 B.H.P. at about 800 revolutions, and was of the armoured type adopted by Messrs. Lahmeyer and other Continental firms, but not much known in England. The design is well adapted for use on a coal-cutting machine, as the massive field-magnets protect the field windings and the armature from damage by falls of roof or accidental injury during working.

At the present there are a few electric side-wheel machines running in Yorkshire collieries which have been developed from the Glass Houghton one, but no particulars of their working have been published. But under suitable conditions they must give economic results.

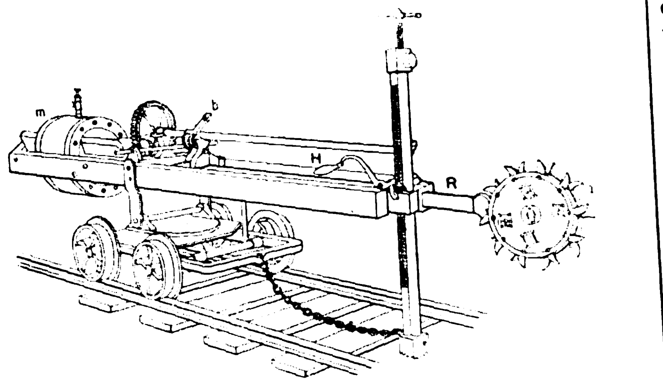

Fig. 128.—Messrs. Wantling and Johnson's Electric Coal Cutter and Heading Machine.

A smaller type rotary wheel machine of American origin is shown in Fig. 128. It is the invention of Messrs. Wantling and Johnson, and was shown at the World's Fair Exhibition, Chicago, 1893. The writer has no particulars about its performance, but it seems to be a practical machine. It is adapted for making vertical or horizontal cuts, but cannot be set to cut level with the floor. It appears to be especially suitable for heading work. The cutter wheels are shown in plan in Fig. 129. There are two wheels revolving in opposite directions to each other. Their diameter can be made to suit requirements. The sketch in Fig. 128 shows the machine arranged for heading, in which case it is always parallel with the rails. For long-wall or pillar and stall working the motor and cutter would be at right angles to the rails and the coal. The method of steadying the cutter is clearly indicated.

The Thomson-Houston "Mowing Machine" coal-cutter, presents several features entirely different to any of the preceding machines. It may be regarded as a modification of the band coal cutters. The teeth are carried on a chain which passes round an overhanging arm capable of rotation through an arc of nearly 180 deg. It appears to be suitable for long-wall working. There does not appear to be any definite information published with respect to its performances.

In spite of the apparent advantages to be derived from the application of electric power to rock and coal drills, there does not seem to be much progress made in this direction. The reasons for this are probably partly the same as those already referred to which have hindered the introduction of mechanical coal-getting, and, in addition, the cost of the conductors, no doubt, has been in many cases prohibitive. But there are also some difficulties peculiar to the work.

Driving stone drifts is about as rough work as can be imagined, and the men employed are as rough as the work. But more important than even the rough treatment is the question of ventilation. Obviously, when driving a heading, there is a tendency for the air to stagnate, and there is difficulty in removing the fumes of powder after shots are fired

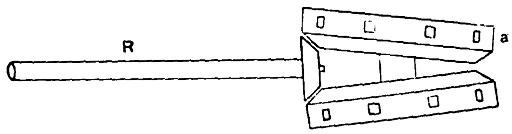

Fig. 129.—Plan of Cutter Wheels of Messrs. Wantling and Johnson's Electric Coal Cutter.

unless fresh air can be brought up to the face. Now the compressed air drill exactly meets this requirement. The exhaust from the drill causes a steady draught which cools and purifies the air, and powder fumes can always be cleared away by turning on a little air. The electric drill, on the contrary, tends, if anything, to increase the difficulty, for the power wasted in the drill raises the temperature of the air at the face of the heading. This disadvantage is probably sufficient, in many cases, to render the use of electric drills impracticable, the mere question of cost of boring (gauged, usually, by work done in well-ventilated spots) being altogether subordinated to other considerations. Of course, for a variety of purposes, such as quarrying, working in well-ventilated spots, &c., these objections have no weight. But even under the most favourable circumstances the electric drill does not seem to have made much progress.

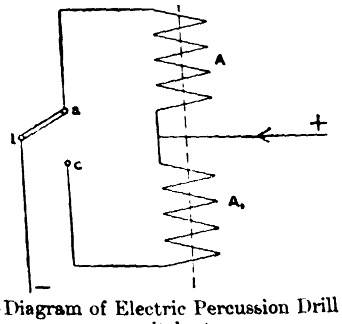

Fig. 130.—Diagram of Electric Percussion Drill with two-way switch at *a c*.

There are two main principles upon which rock drills are designed: the rotary and the percussive.

The rotary type is usually driven through gearing from a small motor. The percussion type is sometimes worked by a motor winding up a coiled spring, which at the proper moment uncoils and spends its energy upon the drill shaft; and, in others, the principle of magnetic attraction is used, the drill shaft being attached directly to the iron core of a solenoid.

Hitherto the motor-driven drills have proved to be the more successful in general work. Several firms build these machines, each having a different way of gearing the motor to the drill shaft, but the general principle is the same. The best known in this country, as well as in America, is the Jeffrey drill. It is chiefly used for working in hard coal, and is found to give satisfactory results. In general the makers design the motors to work at a pressure of 220 volts; but this can be varied to suit special requirements. The rated output of the drills for 2in. holes is

Digitized by Google

2 H.P., but a factor of safety of two is allowed. They are stated to drill, in the hard "boney" found in anthracite mines, a 2in. hole, 6ft. deep, in from 2min. to 2½min., while in the coal they will cut a similar hole in less than a minute. One of these drills is in use at Newbattle Colliery, Dalkeith. The manager, Mr. John Morison, reports that it makes, in the hard splint coal, a 2in. hole, 4ft. deep, in the space of 5min., including the setting of the drill. This, he adds, is equal to the work of four men, while the Jeffrey drill only requires one man.

Various English firms have built electric drills for mining work, but, judging from the number in use, none of these have been so successful as the Jeffrey drill.

The reciprocating action of a solenoid is apparently well suited for actuating percussion drills. Yet the solenoid, energised by a continuous current, is the least effective means of using magnetic power through comparatively long distances. Its proper function is to attract an armature through a very short range or to hold it firmly in position.* However, in spite of this manifest disadvantage, solenoidal action offers so many advantages in the design of percussive drills that it appears more than probable that this type of drill will ultimately come into more general use than the motor type. Therefore a brief reference to the subject may be useful.

The earliest attempts to utilise the principle were made in accordance with the diagram shown in Fig. 130. The current was supplied to the centre of two coils forming the solenoid, and was passed through them successively; the changing being controlled by means of a two-way switch, indicated at *a* and *c*. The iron shaft of the drill formed the core, and was attracted first by one coil and then by the other. This is a very wasteful design, for the power absorbed during the instroke is the same as that during the outstroke. In addition to this objection is the trouble given by the contacts at the switch points.

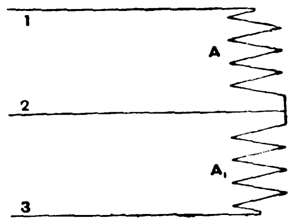

FIG. 131.—Diagram of Electric Percussion Drill, for use on a two-phase circuit. No switch required.

An improvement is possible by the use of a single solenoid drawing in a plunger against a strong coiled spring. The blow given by the recoil of the spring is very rapid, and resembles the impact of a hammer if the bit be at the right striking distance; and, further, the instroke is made comparatively slowly, and does not shake the drill carriage. In case the stroke is too short to strike the work a spring cushion is provided to receive the blow. The opening and closing of the circuit, however, remains, and practically renders the design useless.

A distinct advance is made by the use of pulsating or alternate currents, or a combination of them. There are many methods, but they all embody the following conditions: No switch is necessary, three or more wires are required, and also, in some cases, a special dynamo. The first is an absolute gain, for there is no trouble from sparking, and the two last are not serious difficulties when it is considered that these drills are only likely to be used in mines and places where it will pay to provide a suitable dynamo if the use of electric drills is deemed advisable. The simplest drill of this class is one coupled to a two-phase circuit as shown in Fig. 131; but it has the objection that the power used on the instroke is nearly as great as that on the outstroke. The number of blows given by drills of these types corresponds with the frequency of the alternator, and they are therefore adapted for delivering many quick light blows per minute rather than a few heavy blows. A frequency of from four to ten per second is found to give the best results.

A still better device is that applied in the Marvin drill. This is of the double solenoid type, and is one of the most successful in America. It is run off a special dynamo giving pulsating currents in two circuits. The connections are shown in Fig. 132. The dynamo armature in its simplest form has only one coil. One end of this is fixed to a continuous metal ring d_1, on which rubs the brush B_1. The other end of the coil is joined to a metal segment, d_2, extending for 180 deg. and concentric with d_1. Two brushes, B_2 and B_3, placed diametrically opposite to each other, rub against it. Three conductors are required; one from the middle point of the solenoid is coupled to B_1, and the ends of the coils are respectively joined to B_2 and B_3. The two coils successively carry a current, and so give reciprocating motion to the drill.

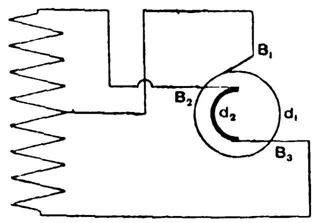

FIG. 132.—Diagram of Marvin Electric Percussion Drill. d_1, d_1, rings on dynamo; B_1, B_2, B_3, fixed brushes.

Probably the best results with reciprocating drills are likely to be obtained by the use of a combination of pulsating and alternating currents; for the instroke can then be made without much waste of power, and yet a very effective blow can be delivered at each outstroke. This principle has been applied in the Van Depoele electric percussion drill. One form of the arrangement is shown diagrammatically in Fig. 133. The dynamo may be of any continuous-current make, with an ordinary commutator, and the two usual fixed brushes at F_1 and F_2; but it requires the addition of two revolving brushes, R_1 and R_2, separated by 180 deg. The coils in the solenoid are three in number, 1 and 3, coupled in opposition to each other, having few turns relatively to the main coil 2. The connections are made as follows:—Coils 1 and 3 are in series with each other, and are coupled to the revolving brushes, R_1 and R_2; these coils are, therefore, traversed by an alternate

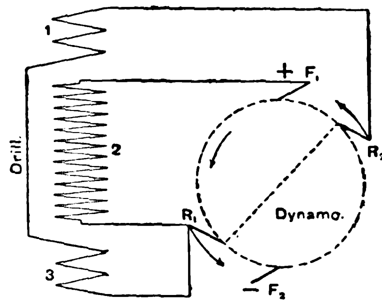

FIG. 133.—Diagram of Van Depoele Electric Percussion Drill. R_1, R_2, revolving brushes; F_1, F_2, fixed brushes; 1, 2, 3, coils of drill.

current. The coil 2 is coupled to the fixed brush F_1 at one end, and at the other to the junction of coil 3 with the rotating brush R_1; it is, therefore, energised by a pulsating current, and exerts the chief effect on the plunger with a polarity always in the same direction. The blow is made mainly by the action of the centre coil, the end coils practically neutralising each other. The return stroke is chiefly due to the resultant pull of the two end coils, as the centre one varies between zero and a maximum. At a first glance there seems to be a departure from simplicity of design without any compensating gain. But, on a closer examination, it will be seen that the design marks a considerable advance, and that the chief difficulties referred to in the early part of this section are met to a great extent.

The instroke can be made as light and the outstroke as heavy as required, both of these desirable ends being attained

* Prof. S. P. Thompson has recently demonstrated that an alternate-current magnet possesses very different properties from those of a continuous-current one. He shows that by means of an alternate current the pull of an electromagnet on its armature may be extended through comparatively long distances and may be even greater, at, say, three inches, than when closer. This important fact probably opens up a new field, and may, therefore, assist in the development of percussive drills.

Digitized by Google

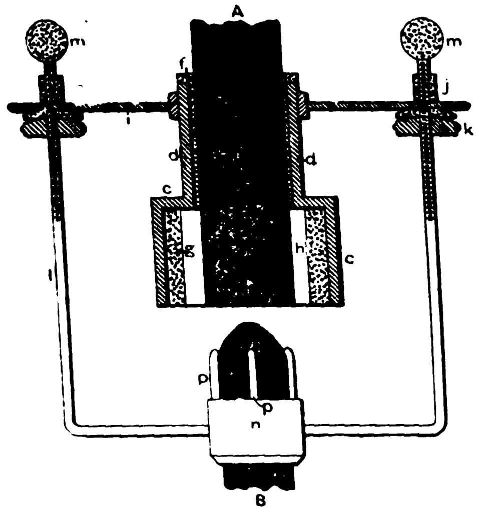
without the use of any switch or complicated gear in the drill. Also only three small conductors are required, and the dynamo gives a continuous current and can be used for lighting or motor work.

The chief difficulty likely to be experienced with the Van Depoele drill appears to lie in the heating of the iron cores from hysteresis and eddy currents. This, however, will be gradually overcome as experience suggests better methods of building the core and framing.

PROLONGING THE LIFE OF ARC LAMP CARBONS.

If it is desired to make a given length of carbon of a given diameter and supplied with a given current at a given pressure burn longer than it otherwise would, it is open to one either to alter the composition and make of the carbon itself or to alter the conditions under which it is burnt. The former mode of procedure has of late mainly occupied the attention of investigators in this country, whilst abroad, and especially in the United States (see *The Electrician*, Vol. XXXI., p. 502, and Vol. XXXIII., p. 592), the latter course has apparently received most attention.

The following is a curious device, due to Herr Francis Jehl and made by F. Hardtmuth and Co., of Vienna, and by the Allgemeine Elektricitäts Gesellschaft of Berlin. The accompanying illustration shows the "burner" in section. It consists of a metal hood, *c c*, surrounding the positive carbon A, the whole being supported by three platinum claws, *p p p*, clutching the negative carbon B. To the top of the hood are soldered the arms *i i*, which are provided with eyes and rest on the insulators *j j*. The upper portion of the apparatus is a cylindrical tube filled with insulating material, *f f*, in which the upper carbon slides easily. At the lower end there is a fireproof lining, *g g*. The upper carbon should project one to three millimetres beyond the hood, and for the purpose of this adjustment the rods *l l* are provided with a screw thread and nut, *k*. The insulating knobs *m m* prevent short circuits in the event of the apparatus coming into contact with the upper carbon.



The efficacy of this expedient depends upon the formation within the hollow chamber *h h* of a layer of more or less stagnant air, which takes the place of the constant stream of hot air which, under ordinary circumstances, always rises from the heated carbons, greatly increasing their rate of consumption.

According to tests by Prof. Schlenk, the consumption in a given time in the case of a 6-ampere arc without the Jehl device amounted to 14·1mm. for the positive and 15·5mm. for the negative (which was presumably of smaller diameter), against 4·9mm. and 10mm. respectively when the hood was used. Again, 9-ampere arcs using an 18mm. cored carbon and a 12mm. plain carbon, each 200mm. long, can be made to last 25 hours with the hood and using a 13mm. lower carbon, as against 9½ hours.

The first cost, average life, and attendant bother, must be taken into consideration before the practical engineer can arrive at the *net* gain obtained by the adoption of the Jehl hood.

A LUMINESCENCE LAMP.

Under this name Herr H. Ebert describes, in the current number of *Wiedemann's Annalen*, a lamp in which luminous paint is utilised to convert the energy of high-frequency alternating currents into light. The oscillations, which are specially adapted to this purpose, are regular and only slightly damped. They have a peculiar power of producing fluorescence and phosphorescence in a degree which is high when compared with the energy consumed. But great as is the luminosity of the phosphorescent body, it is not perceptibly heated by even the strongest alternating currents, and hence the energy consumed is so slight. The lamp consists of a glass tube containing a cake of luminous paint, such as that supplied by Messrs. Schuchardt under the name of "greenish-blue luminous paint." The tube is then sealed and mounted in a glass globe, which is highly exhausted and provided with tinfoil rings on the outside, carrying hooks for the conducting wires. As soon as electric oscillations impinge upon the tinfoil, cathode rays are formed in the interior normal to the surface of the glass, which, though only slightly luminous in themselves, produce vivid luminescence phenomena in the tube.

In order to obtain an idea of the economy of these luminous processes, which is exceedingly great, the author instituted a series of measurements; "but," he says, "it would lead too far to give all the details. I shall therefore only add some remarks concerning the results obtained, and reserve a further treatment of these questions to a future occasion.

The luminosities were measured by means of Glan's spectrum photometer, and compared with von Hefner-Alteneck's standard amyl-acetate lamp. Luminosities of $\frac{1}{30}$th to $\frac{1}{10}$th of an amyl unit were found. In determining the electric energy consumed such direct methods of measurement in the case of these high-frequency currents met with difficulties already emphasised from other quarters. Since, however, it was only a question of determining the order of magnitude, this energy was calculated.

The amount of energy present at each discharge on the secondary condenser was calculated with sufficient accuracy from the capacity of the terminal condenser and the effective potential, after allowing for the damping. It was further assumed, as the least favourable case, that the "luminescence lamp" introduced consumed all this energy alone. That this is not the case is apparent on placing another lamp or a simple exhausted tube beside it; it also shines, and the luminosity of the first lamp is only slightly reduced. Thus we obtain a superior limit of the amount of energy, while the energy actually consumed is sure to be much less. Yet it appears that in this manner it is easy to construct bright lamps which only consume *millionths of watts*. The economy of these lamps is correspondingly favourable. On comparing the brightness of these lamps in the visible spectrum with that of the amyl-acetate lamp, and calculating for both sources the *total* energy required for their maintenance (for the amyl-acetate lamp it is best to use the numbers given by E. Wiedemann or Tumlirz for the total radiation), it appears that this "high-frequency lamp" requires about 1,500 or 2,000 times less total energy than the standard lamp named. The "useful effect" is therefore very high."

The apparatus used for obtaining these high-frequency currents was a Lecher wire combination, provided with one bridge. The source of energy was an induction coil, an influence machine, or a sufficiently highly transformed alternate current. The dimensions of the primary and secondary circuits were chosen so as to insure the least possible amount of damping. The secondary condenser had an electrostatic capacity of $1{\cdot}1 \times 10^{-5}$ microfarad. The oscillations had wave-length of about 42m., and a frequency of about seven million per second. The logarithmic decrement of the oscillations in the secondary circuit was 5×10^{-4}. Thus, any given oscillation impulse would pass to and fro 20,000 times before falling to the 2·7th part of the original amplitude. By increasing the number of sparks, which does not require a large increase of energy, the pressure between the two branches of the secondary circuit may be kept in almost continuous alternation, since the damping is so small that the oscillations due to the next spark begin before those started by the last have died out. As regards practical difficulties to be overcome, the principal one would be the enormous inductive resistance offered to high-frequency currents by copper mains. But the transformation to the high frequency might take place at the lamp itself, especially as condensers of only small capacity and inductance could be employed.

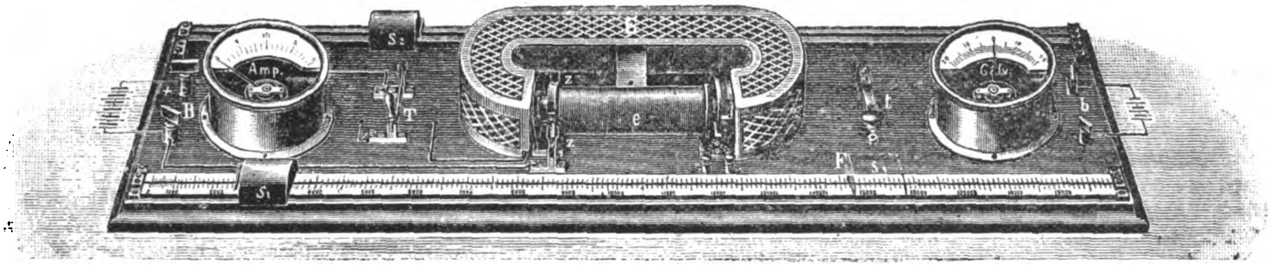
A MAGNETIC TESTING MACHINE.

In this instrument, which is made by Hartmann and Braun, the property possessed by bismuth of altering its resistance in a magnetic field is taken advantage of. A thin wire of chemically pure bismuth is prepared and insulated, wound into a flat coil non-inductively, and soldered to two flat copper strips held together in an ebonite holder, furnished with terminals; the coil being protected from injury by mica plates. If such a coil be placed in a magnetic field, the alteration of its resistance is a measure of the field; and a field of 1,000 corresponds to an alteration of resistance of about 5 per cent. The coil is only 1mm. thick, and can be introduced into narrow slits.

resistance; the measuring bridge being so arranged as to give the field directly in C.G.S. units. The measurement is performed as follows: a piece of the iron under test, as nearly as possible of the exact dimensions of the standard piece is taken, 200mm. long and 25mm. thick and is put through the loose coil, and placed between the electromagnet poles in such a manner as to be tight up against the left-hand pole. A source of E.M.F., preferably an accumulator giving current up to 15 amperes, is connected to the terminals B; and to *b* two or three cells are connected. Then the travelling contact S_1 of the front measuring wire is moved to zero on the wire, the key *t* is pressed, and the galvanometer brought to



The figure shows the apparatus. An oval magnet is fixed to the base board, one long side of which can be removed, and replaced by the test bar; on the board is also an ammeter with a strong switch, T, for measuring the magnetising current, and on the other side are a galvanometer and key, *t*, for measuring the zero by moving the slider S_2. Then the magnetising current is put on by closing T, its amount read on the ammeter, and a new balance obtained on the galvanometer by the slider S_1 and the key *t*. The field is then read on the front scale by the position of the slider S_1.

OPENING OF THE ELECTRIC SUPPLY STATION AT WORCESTER.

The formal inauguration of this important undertaking by the Corporation of Worcester took place on the 11th inst., a technical description of which has already been given to our readers. By invitation of the Mayor (Mr. G. H. Williamson) the members of City Council and other citizens, together with a number of electrical engineers, met at the Guildhall in the morning, and, preceded by mounted police, drove in brakes to the generating station at Powick. On arriving there the Mayor was presented with a gold key by the building contractor, Mr. Rowbotham, wherewith to open the large entrance door. This having been done, the party entered the generating station, where all the arrangements had been made for starting the machinery. The Mayor, in addressing the party, after dwelling on the fact that every ratepayer was a shareholder in this new enterprise, remarked that they would have a profitable business on the co-operative principle, and at the same time they would be selling a commodity which was a distinct advantage to the health of those who used it in preference to gas for illuminating purposes, and also would be a cheaper substitute. The Mayor then proceeded to deal with the proceedings taken in connection with the work, especially complimenting Mr. Preece on his great ability in preparing the scheme and advising them, the Brush Company on the manner their share of the work had been done, Mr. Caink (the city engineer), Mr. Rowbotham (the builder), and others who have been connected with the undertaking.

Mr. W. H. Preece, having spoken on the great advantages of having water power, remarked that a diagram showing the load on a station at different times of the day invariably pointed to the heaviest hours as being between 4 p.m. and 9 p.m., thus showing that for the remaining 19 hours the machinery is virtually idle, but it must be kept going. The result, he pointed out, was that the cost of electric lighting was much enhanced by the waste of fuel during those hours; whereas here, water running to waste, as the waters of the Teme had done for centuries past, gave them just the very agency that they required to keep the light going at a minimum of expense.

Mr. W. M. Mordey and Mr. Geipel, of the Brush Company, also spoke, the Mayor then starting one of the turbines, amid loud cheers, wishing "Success to the electrical works of Worcester" and "To the future reduction of rates."

The almost complete absence of noise in the working of the machinery was the subject of much remark. The Mayor then proceeded to the switchboard, and turned on the station lighting. After an inspection of the engine room and boiler house, the party left the station and drove to the waterworks. There an inspection of the electrical machinery being erected to pump water to the higher levels of the city took place, the party being addressed by Mr. Hughes, the Chairman of the Water Committee, Mr. Mordey, and the Mayor. The motors at the waterworks are supplied with power from the Powick water-power station.

Upon returning to the Guildhall, luncheon was provided by the Mayor in the Council Chamber, at which Sir Douglas Galton and others spoke. Luncheon over, the party proceeded to the Public Hall, where the Electrical Exhibition was opened by the Mayoress; a reception, at which there was a large attendance, being subsequently held.

The Exhibition, which has proved very attractive, includes examples of almost every application to electricity, thirteen firms taking part in it.

Later in the evening the Mayor entertained some 300 guests at a banquet held in the Guildhall to celebrate the inauguration of the electricity works.

A very pleasant evening was spent, thus bringing to a close one of the most eventful days in the modern history of the "faithful city," Worcester being thus named because of its loyalty to the Royal House of Stuart.

We may mention, in conclusion, that the lighting of the streets, Guildhall, and several private consumers, amounting to an equivalent of nearly 5,000 8-c.p. lamps, has proved most successful, and has worked without a hitch both on the opening night and since with water power entirely as its motive power. Our thanks are due to Mr. F. R. Davenport (Mr. W. H. Preece's representative) for particulars of the inauguration and working of the plant at the Worcester electric supply station, which will, we hope, prove to be not only one of the most interesting, but also one of the most successful stations in the kingdom.

WATER-DRIVEN DYNAMOS.

On a former occasion we discussed the considerations which are involved in deciding whether a particular mill-site is worth using for the supply of electric power. We observed that there are but few mill-sites in this country where the conditions are at all favourable to the requirements of an electric generating station; and we remarked that when this side of the question has been settled, and the mill-site has been adopted, there still remains the question of the best way to arrange the hydraulic and electrical machinery. Probably the wide difference of opinion which might be expected from the engineering profession, as to the suitability of any given mill-site, would be as nothing to the range of views which would be advanced with regard to the best type and arrangement of machinery to adopt. As only one small electric supply station in this country, namely, that at Buckingham, is driven by old-fashioned waterwheels, and as this is an instance where the plant had been already erected before the electrical engineers took over the mill-site, it may fairly be supposed that engineers would be unanimously in favour of turbines.

But, to begin with, there are several different types of turbines, for the best makes of each one of which an astonishingly high efficiency is claimed by its maker; and, in the next place, there are a great many ways in which any given type of turbine may be set, in one and the same fall. It is this question of turbine setting which, from the electrical point of view, is of special importance. Whether, shall the turbine be placed so as to drive direct on to the dynamo shaft—most efficient of settings, but often awkward to arrange—and if so,

Digitized by Google

shall the shaft be horizontal or vertical; or, shall the difficult knot be cut by sacrificing the direct-drive and employing all manner of gearing? Not merely fanciful considerations, but vital questions of economy are involved in the choice between these three plans.

Thus far, the practice in British water-power stations has been wholly in favour of the use of gearing; although it is by no means evident that this solution is the best possible one. There have been two causes which have influenced this choice. Firstly, the British mill-site is, even at its best, but a sorry business; so low in head, as a rule, and so liable to flood and frost and drought. From this cause it has been almost a necessity, and in some places quite a necessity, to use what are called "drowned" turbines—*i.e.*, turbines which can work below the level of the tail water, and which have all their passages full of water. It is easy enough to have a drowned turbine, but it is another thing to have a drowned generating station. Hence the difficulty of working by a direct-drive between the turbine and the dynamo on such falls as that at Worcester—falls where the drowning of the tail race is a regular occurrence which must be taken into account in the design of the station. But, it may be said, why not let the drowned turbine work directly on to the undrowned dynamos by means of a vertical shaft, as they do at Niagara? The answer which British water-power practice gives to this question is that there are other things to be taken into account. There is the ever-present necessity for steam plant, to meet the exigencies of frost and drought; and English engineers have not yet seen their way to building a steam engine which will drive a dynamo on a vertical shaft, although the very similar problem of so driving a vertical spindle centrifugal pump has long ago been solved. The experiment might be tried; it is by no means self-evident that it is better to stick to existing models and use the complicated and power-wasting gears, such as are to be found at Worcester and other places. However, in this need for steam plant, we may see the second of the two causes which have led to the adoption of geared plant wherever water-power has been used in this country for electric supply. Nor is the gearing of that simple kind which is to be found in the decadent practice at some steam-driven stations. A mere single drive with ropes is credited with from 6 to 10 per cent. "solid loss," as Mr. RAWORTH put it at the Institution of Electrical Engineers last session. What "solid loss," then, must be expected when there is not merely a single change of speed by rope or belt drive, but double or treble change with the use of bevel cog wheels and countershafts? We cannot accept as an answer that the waste of energy is unimportant, because "water power costs nothing." Water power costs nothing only in the same sense that coal costs nothing to the man who has previously purchased the freehold of a coalfield, and has sunk capital in developing it.

Nevertheless, whether the practice be good or bad, these are indubitably the causes which have developed the present type of British water-power station; a type which may be defined as a geared turbine station, with geared steam engines for reserves of power. Hitherto it cannot be said to have been a successful type; but it remains to be proved whether the element of failure is inherent in the mode of using water-power or in some other cause. We can never expect, in this country, to be able to adopt the type of water-power station which is common in Switzerland, Italy, and other countries where mill-sites are highly favourable; nor, it would seem, do engine builders think it worth while to so modify auxiliary steam plant as to render our own unfavourable mill-sites capable of being utilised in other than the present imperfect manner.

REVIEWS.

Die Prinzipien der Mechanik. In neuem Zusammenhange dargestellt. ("The Principles of Mechanics." Exhibited in a new form.) By HEINRICH HERTZ. (Leipzig: J. A. Barth. 1894.)

Although nearly a year has elapsed since the memorable death of Heinrich Hertz, fresh proofs are still continually afforded us of the marvellous insight into the intricacies of pure science which he displayed. The work which culminated in the almost complete verification of Maxwell's electromagnetic theory, would have been, in itself, more than sufficient to rank the name of Hertz with the greatest names in the annals of science; but, in addition to this, he has shown evidence of the most remarkable versatility in all scientific problems. We have hitherto known him as having been the greatest exponent of the powers of experimental research of his time; we now are shown his capabilities as a mathematician.

In the volume under consideration we have the result of his researches during the last three years of his life, which forms, indeed, a worthy sequel to the work which preceded it. The principles of mechanics are investigated by a new mathematical process, which is so perfectly arranged that all the results which have hitherto been obtained by independent methods of treatment in different hands, are brought into concordance as particular cases of the results of this treatment. Nor is this all. In most other treatises on mechanics, appeals are made to experience, by the aid of Newton's laws of motion, and the doctrine of the conservation of energy. In this book, Newton's first law is the only fact assumed from experience; the other two laws of motion, and the conservation of energy, are deduced from it. The results, too, are of such generality that some of them appear to be beyond the test of present experience, and their verification must be left to future research. It is unfortunate that, in a work of such magnitude, the finishing touches should not have been given by the author's hand; but the fact that the editing of the book has been delegated to Dr. P. H. Lenard, who has himself conducted a large number of important investigations in the same direction as Hertz, is sufficient guarantee of the care with which this has been carried out.

After a few introductory remarks by the editor concerning the intentions of the author with respect to the publication of the work, a preface is given by the late von Helmholtz, who was mainly instrumental in turning the thoughts of Hertz, when a student, in the direction in which he was afterwards to attain such brilliant results. This preface treats chiefly of the life and character of Hertz, with a history of his researches; and in addition gives a short account of the progress of the science of mechanics, and the evolution of the system adopted in the book.

In the introduction, the author gives an exceedingly interesting and valuable dissertation on the methods of scientific investigation, and enunciates the principles, which should guide us to the selection of the method most suited to the extension of our knowledge, and by which we may judge of the value of the conclusions derived. Three chief methods of treatment of the subject of mechanics are discussed in relation to these principles, the first being the customary method, in which the subject is historically treated, commencing with the principles of Archimedes, and thence to those of Galileo, Newton and Lagrange; the second, in which the conception of energy is fundamental, in addition to space, mass, and time; and the third method, in which space, mass, and time are fundamental independent conceptions, and that of force or energy is taken as a starting point. Of these three methods, the author discards the second, and considers the third most suitable. This method is adopted in the book.

The work is divided into two parts: the first, "On the Geometry and Kinematics of Material Systems," being devoted, as its title indicates, to the consideration of the relations of the fundamental conceptions of space, mass, and time, in accordance with the third method of treatment. In the

Digitized by Google

first chapter these quantities are defined, space and time being considered as conceptions of our inner consciousness, whilst mass is defined as being made up of mass particles, each of which is "an attribute by which we distinguish between a known point of space at a given time and a known point of space at any other time (Ein Massenteilchen ist ein Merkmal durch welches wir einen bestimmten Punkt des Raumes zu einer gegebenen Zeit eindeutig zuordnen einem bestimmten Punkte des Raumes zu jeder anderen Zeit)."

The second chapter deals with methods of fixing the position of points in space, and the configuration of systems, together with the analytical treatment of finite displacements, in which the peculiar notation of the book is introduced. Each problem is considered in two ways; with respect to Cartesian co-ordinates, and to generalised co-ordinates. The notation is admirably adapted to the subject, but might possibly be even further improved by the introduction of vector methods, which would in most cases obviate the necessity for the duplication of results, and would assist the comprehension of their physical meaning. These methods, however, do not seem to have made the same advance in Germany that they have here. The third chapter gives the same treatment of infinitely small displacements.

The fourth chapter is devoted to the consideration of the possible and impossible displacements of material systems, and requires careful perusal. It commences with definitions of different classes of systems, and their relations; and gives their equations of condition, introducing the principle of virtual displacements. In Chapters 5 and 6, the conditions for the straightest and shortest paths are investigated by the method of undetermined multipliers, and also surfaces of position and their orthogonal trajectories, leading to Jacobi's law.

In the sixth and last chapter the Kinematics of systems are considered, in an account of the vector quantities of a system, and their components in various directions. The motion of systems, their velocity, momentum, acceleration, and energy are investigated; and, in conclusion, the elementary forms of Lagrange's equations are deduced.

The results given in this book, as the author states, appear very unusual when compared with experience. It must, however, be remembered that they are entirely deduced from our fundamental conceptions of space, mass and time; and do not in any way depend on experience, which, therefore, cannot be adduced in confirmation or contradiction of the results.

In the second book, entitled "The Mechanics of Material Systems," in accordance with the treatment indicated in the introduction, the results of the first book are assumed; and are brought into accordance with experience, by assuming a principle deduced from experience. Space, time, and mass are first re-defined with respect to our practical measurement of them, including the definitions of the first book; and material systems are also re-defined in accordance with these new definitions. In the second chapter the fundamental principle of the book—viz., Newton's first law of motion—is introduced, and this principle is discussed in its bearing on the results of the first book.

The third chapter treats of the motion of free systems, and first establishes Jacobi's law of least work, and the principle of the smallest time integral of energy. The differential equations of motion are then established, in Lagrange's forms for generalised co-ordinates, and in Poisson's and Hamilton's forms. Systems with internal constraint are then discussed, and D'Alembert's principle deduced. The motion of Holonomous systems is investigated, and also the theory of dynamic models.

In the fourth chapter constrained systems are dealt with, and force is introduced as being "the independent influence which the one, of two connected systems, exercises on the motion of the other, following the fundamental principle," from which Newton's third law is deduced. Motions of systems under the influence of external and internal forces are also investigated.

The fifth chapter is devoted to systems with virtual masses, and first treats of cyclical motion and its properties. This part is the most interesting and important to electrical students, as from these systems Maxwell's dynamic analogies to currents in circuits were deduced. Expressions are obtained for the equations of motion, corresponding to the laws of currents in circuits, and the energy and work of the system, corresponding to those of a current. Conservative systems are also treated of, and the usual result of the constancy of the sum of kinetic and potential energy deduced. Hamilton's potential functions are also studied.

In the sixth and last chapter discontinuous motions are discussed, and the theory of impulses. The equations of motion are studied for systems with external and internal impulses, and also for connected systems under the same circumstances.

In conclusion, the author considers the effect of the accuracy of the fundamental principles on the results deduced, and also the defensibility of applying these principles to systems under constraint.

The plan of the whole work appears to be most admirably adapted to the logical sequence of the theorems. It may almost be said that the science of mechanics has, in this book, been reduced to the same rigidity as that of geometry in Euclid.

The applications of such a work are not far to seek. It will probably give a new impulse to the mathematical treatment of molecular physics, which is at present pushed to the limits of the methods hitherto known. Such extensions, too, will probably prove the surest way of verifying or disproving the conclusions given. The problems which most immediately suggest themselves are those of the sciences of Thermodynamics and of Electromagnetism, and last, but not least, the problem of the constitution of matter. It is to this end that all our scientific investigations are tending, and it will be the greatest tribute to this, the last work of Heinrich Hertz, if, by its means, we are enabled to advance further towards that goal.

THE CHEMICAL THEORY OF ACCUMULATORS.—V.

BY E. J. WADE.

The thermo-chemistry of the discharge phenomena having been considered, it remains to examine it in its more purely chemical aspect. To begin with, the occluded gas theory may be put aside as having no evidence at all to support it, while, as has been already mentioned, the results of the experiments of Gladstone and Tribe, Frankland and others are directly against it. This practically limits the discharge reactions to the formation of one or both of two classes of compounds, namely, oxides (lower than PbO^2) and sulphates.

Now, it is a perfectly well-established property of the oxides of lead that none of them, with the exception of the peroxide (PbO^2), can exist unacted upon in solutions containing more than a very small percentage of free sulphuric acid. Litharge or massicot (monoxide PbO) is directly converted into lead sulphate with the liberation of water.

$$PbO + H^2SO^4 = PbSO^4 + H^2O.$$

The sesquioxide (Pb^2O^3) and minimum or red lead (Pb^3O^4) behave as if they were mixtures of monoxide and peroxide; that is to say, they break up into mixtures of sulphate and peroxide.

$$Pb^2O^3 + H^2SO^4 = PbO^2 + PbSO^4 + H^2O.$$
$$Pb^3O^4 + 2H^2SO^4 = PbO^2 + 2PbSO^4 + 2H^2O.$$

It is true that these reactions do not take place with great rapidity, and that a considerable time may elapse before the final portions of oxide are completely acted upon; but this is due to the protective powers of the insoluble sulphate, which, as fast as it is formed, clogs up the pores and impedes further access of acid to the interior of the mass; and this effect will naturally become more marked as the proportion of sulphate present increases.

In view of the above facts it seems unreasonable to suppose that oxides are formed or exist in lead cells in the presence of free sulphuric acid, as to do so implies that their chemical properties or affinities are then entirely modified in some way or another.

Digitized by Google

Undoubtedly very incomplete sulphating, accompanied by the formation of large quantities of monoxide, did occur in many of the earlier forms of pasted cells, and occasionally in more recent ones, but a close examination would reveal the fact that in all such cases the supply of acid in the pores of the active material was insufficient, owing, either to the solution being too weak, or to imperfect diffusion from the active material itself being too dense and used in too large unbroken masses, such as are obtained when a considerable quantity of it is packed round a central conducting core or into a hollow receptacle. (This does not necessarily imply that comparatively large blocks of active material may never be used, for if they are sufficiently porous they may be far more efficient than a more subdivided material which does not possess this property in so high a degree.) The inevitable result of discharge under these circumstances is, that almost the whole of the acid is very soon withdrawn from the electrolyte immediately surrounding the inner surfaces of the electrodes, and then a formation of a mixture of monoxide and sulphate does certainly take place; but this cannot be considered to in any way represent the normal working conditions.

While, however, the assumption of the formation of oxides is opposed to all chemical knowledge, it appears at first sight that, as far as the positive electrode is concerned, it is equally opposed to the laws of electrolysis to assume a direct formation of sulphate, and in order to reconcile these two conflicting points of view the theory was propounded that although sulphate is the ultimate product, the reaction takes place in two stages; first a reduction of the peroxide to monoxide, which is a normal electrolytic action, and then an immediate conversion of the monoxide into sulphate by a heat-producing "secondary" or "local" action. With the exception of Mr. Swinburne, who has been an uncompromising advocate for the direct sulphating of the positive from the very first, this view has been the one most generally held since the publication of Messrs. Gladstone and Tribe's researches in 1883, and probably still remains so at the present time.

The electrolytical difficulty lies chiefly in comprehending how it is possible to obtain any E.M.F. from a cell in which the same compound is formed at both poles, much less for it to be proportional to the *sum* of the two effects; and the case is considered as if it were similar to that of two plates of zinc both dissolving in sulphuric acid to form zinc sulphate and neutralising each other's E.M.F. The objection is, however, only a superficial one, based on loose and erroneous news of what is essential for a galvanic action and the generation of an E.M F., and gives way when carefully looked into.

Consider the following electrolytic equations:—

$$\mathrm{Zn}\,|\,\mathrm{SO^4\,H^2}\ \ \mathrm{SO^4\,Cu}\,|\,\mathrm{C} = \mathrm{Zn\,SO^4}\ \ \mathrm{H^2\,SO^4}\ \ \mathrm{Cu}\ \ \ \mathrm{C} \quad (1)$$

$$\mathrm{Zn}\ \ \mathrm{SO^4\,H^2}\,|\,\mathrm{SO^4\,Cu}\,|\,\mathrm{SO^4}\,|\,\mathrm{C} = \mathrm{Zn\,SO^4}\,|\,\mathrm{H^2\,SO^4}\,|\,\mathrm{Cu\,SO^4}\,|\,\mathrm{C} \quad (2)$$

$$\mathrm{Zn}\,|\,\mathrm{SO^4\,H^2}\,|\,\mathrm{SO^4\,Zn}\ \ \mathrm{SO^4}\ \ \mathrm{C} = \mathrm{Zn\,SO^4}\ \ \mathrm{H^2\,SO^4}\ \ \mathrm{Zn\,SO^4}\ \ \mathrm{C} \quad (3)$$

$$\begin{array}{l} \mathrm{Pb}\ \ \mathrm{SO^4\,H^2}\,|\,\mathrm{O}\ \ \ \mathrm{Pb}\ \ \mathrm{SO^4}\ \ \mathrm{C} = \mathrm{Pb\,SO^4}\,|\,\mathrm{H^2}\ \ \mathrm{O}\ \ \ \mathrm{Pb^4\,SO}\,|\,\mathrm{C} \\ \qquad\qquad\qquad \mathrm{O}\,|\ \ \mathrm{H^2}\,| \qquad\qquad\qquad\qquad |\,\mathrm{O}\ \ \ \mathrm{H^2}\,| \end{array} \quad (4)$$

The first is that for the reactions taking place in a Daniel's cell, in which the zinc is immersed in dilute sulphuric acid and a carbon electrode used to receive the deposited copper; modifications of the most usual practice which can be, and, indeed, actually are sometimes made, without in any way interfering with the principles of the cell's action. As is well known, its E.M.F. and the resultant energy liberated are due to the difference between that generated in the formation of zinc sulphate at one pole, and that absorbed in the decomposition of an equivalent amount of copper sulphate at the other pole.

Equation (2) represents the same combination with the addition that free sulphion (SO^4) is supposed be present at the carbon electrode to combine with the copper which would otherwise be deposited. What may be termed a double depolarisation now goes on, the copper sulphate acting as a depolariser with respect to the hydrogen of the hydrogen sulphate (sulphuric acid) and the sulphion as a depolariser with respect to the copper of the copper sulphate; and the ultimate result is the *formation* of a compound at both poles—zinc sulphate at the one, and copper sulphate at the other; while the whole energy and E.M.F. due to the formation of zinc sulphate is now realised.

In equation (3) the copper sulphate is replaced by zinc sulphate solution. This does not affect the E.M.F. of the cell, which is still simply that of the formation of zinc sulphate or about 3 volts and yet *identically the same compound is now being simultaneously produced at both poles.* Of course, such a cell is not practical, because sulphion cannot be obtained in a free state and certainly could not exist as such in an aqueous solution; but if it is replaced by chlorine and, at the same time, zinc chloride substituted for zinc sulphate, and hydrogen chloride for hydrogen sulphate, a perfectly possible combination is obtained whose action may be represented by the following equation:—

$$\mathrm{Zn}\,|\,\mathrm{Cl^2\,H^2}\ \ \mathrm{Cl^2\,Zn}\,|\,\mathrm{Cl^2}\ \ \mathrm{C} = \mathrm{Zn\,Cl^2}\ \ \mathrm{H^2\,Cl^2}\,|\,\mathrm{Zn\,Cl^2}\ \ \mathrm{C}, \quad (5)$$

and one which also forms the same compound—now zinc chloride—at each electrode. The combination may be yet further simplified by doing away with the acid altogether, and placing the zinc direct in the zinc chloride solution without practically affecting its E.M.F. or the compound produced—still zinc chloride at both poles—

$$\mathrm{Zn}\ \ \mathrm{Cl^2\,Zn}\,|\,\mathrm{Cl^2}\,|\,\mathrm{C} = \mathrm{Zn\,Cl^2}\,|\,\mathrm{Zn\,Cl^2}\,|\,\mathrm{C}\,; \ . \ \ . \quad (6)$$

but it now corresponds to one—the "Upward" cell—which has been used with some considerable success for small lighting installations and other purposes, and gives an E M.F. of about two volts per cell in spite of this double formation of zinc chloride. Theoretically, the E.M.F. of such a combination lies between 2·1 and 2·4 volts, according to the strength of the solution.

To return to equation (4) which represents the discharge of a lead storage cell on the assumption that lead sulphate is formed at both electrodes; a backing of carbon instead of lead for the lead peroxide being supposed in order to facilitate comparison with the other equations. The peroxide acts as a depolariser towards the hydrogen of the acid, half of its oxygen being abstracted, and a further portion of acid acts as a depolariser towards the mon-oxide so formed, with the production of lead sulphate and water; but there are no grounds for discriminating between the two actions and saying the one is electrolytic and the other not, any more than there would be for treating the combination of zinc and copper with sulphion in equations (2) and (3) or with chlorine in equations (5) and (6)—the similarity of whose reactions will at once be observed—as mere heat-producing secondary actions.

The fact is, the whole tendency of modern theories of galvanic and electrolytic action is to show that the old time distinctions between "primary" and "secondary" actions is purely artificial and cannot be maintained. Only a few months back Ostwald emphasised this point in a Paper, reproduced in *The Electrician* for June 29th of the present year, on "Modern Electro-Chemical Theory and its Bearing upon the Practice of the Future," and showed that the whole of the reactions, *as indicated by the ultimate products at either pole*, must be considered equally electrolytic. The specific example selected to illustrate the subject was singularly apt, being the stock textbook one of the electrolysis of a solution of potassium sulphate, which was always said to be first split up into potassium and sulphion by a primary electrolytic action and then these substances combined with water to form potassic hydrate with the liberation of hydrogen, and hydrogen sulphate with the liberation of oxygen, by a secondary chemical action. Now, however, the only action that can in any way be considered as secondary is the gradual combination that will take place, *not at the electrodes* but in the body of the solution, between the free potassic hydrate and free sulphuric acid to reform potassium sulphate.

As regards the negative electrode, no difficulties stand in the way of assuming its direct conversion into sulphate; in fact, this appears to be the only action possible. It is well known that in strong solutions of acid, it takes place by local action with a liberation of hydrogen, exactly in the same way as zinc is acted upon, and the tendency must exist, therefore, in weaker solutions. Doubtless, however, low oxides and hydrates will also be produced should the solution be abnormally weakened

Digitized by Google

in correspondence with the modifications that take place at the positive electrode under these conditions.

So much, then, for the *a priori* arguments based on deductions from general chemical and electro-chemical principles, and which are all in favour of the double sulphating theory of discharge. How, now, is this conclusion supported by direct observation and experiment?

Owing to the difficult nature of the chemical analyses involved, extremely few reliable and systematic investigations are available. Those, to which frequent reference has already been made, of Messrs. Gladstone and Tribe and of Dr. Frankland in 1883, both proved that sulphate was formed in increasing quantities as the discharge proceeded, and was the only normal product at either electrode. Very few details are given as to the precise nature of the cells, but small pasted plates, specially prepared for the purpose, appear to have been employed. Seven years later Prof. Ayrton made public the results of some experiments performed under far more practical conditions, which fully confirmed the above conclusions. Cells of a well-known type (E P.S. 7L, 1888 type) were used, and were charged and discharged at their normal working current. At various periods during these processes portions of the active material were abstracted from both electrodes and subjected to analysis by Mr. Robertson; while at the same time all changes in their colour, degree of hardness, &c., were carefully noted. All the figures are given, however, in terms of the *percentage* composition of the paste, and, in no case, were any quantitative analyses made in the sense of determining the *total* quantity of sulphate formed or peroxide reduced, so it is impossible to institute any comparison with the amounts calculated from the ampere-hours obtained. The same result may be arrived at, however, by considering the amount of acid withdrawn from the electrolyte, as indicated by changes in its specific gravity; but the liquid must be kept uniform by stirring or other means, and even then the results will only be approximately correct, as the acid in the plates will never be quite the same strength as that surrounding them, unless they are exceptionally thin. Such observations have been made by Frankland, Shenck and Farbaky, Kohlrausch and Heim, Ayrton and many others, some of which agree fairly well with the hypothesis of the formation of normal sulphate, while others show considerable discrepancies, and have been used to support arguments in favour of basic sulphates; but it is more probable that they are really due to experimental errors from the cause given above.

The real arguments in favour of the formation of basic sulphate lie in quite another direction. The difficulty of forming a perfectly satisfactory physical conception of the way in which large quantities of lead sulphate can be alternately produced and broken up during the processes of discharge and charge, was referred to in the second article of this series, and the direction in which an explanation must be sought suggested; but it is now time to examine into the question a little more fully.

In the first place it must be borne in mind that the active material in all electrodes, whether of the Faure, Planté, or any other type, is obtained by its reduction, either chemically or electro-chemically, from other compounds more bulky than itself, and exists in a state of molecular subdivision far finer than could be produced by any mechanical means. The electrolyte may be considered, therefore, as having a more or less free access to almost every individual molecule of which it is composed, and at the commencement of discharge the formation of sulphate will take place more or less uniformly throughout the whole mass. Now, one of the most frequently observed facts with regard to lead storage cells has been the large percentage of material that remains unacted upon at both electrodes at the end of a discharge. In some early experiments of Mr. Swinburne's he found this to be over 90 per cent., and the proportion differs probably with every different type of cell, but 50 per cent. appears to be the maximum proportion that is ever converted into sulphate during a normal discharge, even under the most favourable conditions; that is to say, every molecule of sulphate at both the positive and negative electrodes has left, as a backing, a molecule of peroxide and metallic lead respectively; and, on recharging, the current is by their means distributed to every portion of the electrode. The sulphate, being so intimately mixed with the unreduced material, cannot impart to it its characteristic white colour, but only causes the electrodes to assume a lighter tint. If, however—owing to over discharging or to local action while at rest, especially when partially discharged—still more sulphate is formed, it must necessarily begin to aggregate into masses which will be more distinctly visible and more difficult to reduce in proportion as their size increases, because the conductive backing is destroyed and the current has no means of reaching them, and hence the formation of that irreducible "white sulphate" so disagreeable to all who have had practical experience of lead storage cells.

This appears to be the most probable explanation of the physical behaviour of the cells, if only the normal lead sulphate $PbSO^4$ is assumed to be produced; but it can be made more complete and satisfactory if the formation of other sulphates is allowed to be possible.

In this case, considering the positive electrode first, every molecule of normal sulphate formed may be supposed to further enter into combination with a molecule of unreduced peroxide to form the basic sulphate $PbSO^4, PbO^2$. The combination is in all probability an extremely feeble one, just a stage beyond the most intimate mixture; but it will, no doubt, endow the sulphate with a certain degree of electrical conductivity, and render its subsequent reduction far more feasible, while the resultant colour will also be something between that of its two component parts. According to this theory "sulphating," commonly so called, now consists in the breaking up of each molecule of the basic sulphate to form two molecules of normal sulphate,

$$\left.\begin{array}{l}PbSO^4\\PbO^2\end{array}\right\} + H^2 + H^2SO^4 = 2\,PbSO^4 + 2\,H^2O,$$

and takes place when the supply of uncombined peroxide runs short, the action being made evident by the appearance of the non-conducting white compound.

This theory is substantially that advanced by Dr. Frankland, who believes he has isolated such basic sulphates; but they break up so easily into mere mixtures that no positive proof of their presence in cells has ever been obtained, while many think they do not exist. Indirectly, however, a good many facts seem to lend support to the possibility of some such compound being formed at the positive electrode.

In the first place all lead salts enter into basic combinations with the greatest ease, a fact which Mendeléeff has emphasised in his well-known treatise on chemistry.

Secondly, it is extremely significant that a positive electrode should be practically exhausted when at most only 50 per cent. of its peroxide is converted into normal sulphate, for this is just the percentage corresponding to the conversion of the *whole* of the peroxide into *basic* sulphate. Up to this point the discharge process will have been greatly facilitated, and have proceeded pretty easily owing to the whole mass remaining more or less conductive; but now a formation of normal non-conductive sulphate sets in which rapidly covers all the free surfaces with an insulating film, and almost entirely stops any further action. An analysis made by Mr. Robinson of some sediment that fell from some positive plates discharged down to a potential difference of 1·6 volts in one of Prof. Ayrton's experiments gave a composition almost identical with PbO^2, $PbSO^4$; and in the course of some other analyses he observed that the residues left after dissolving out the peroxide with nitric acid, although presumably pure normal sulphate, were a brownish yellow colour, and only became white after boiling with the acid, which is very suggestive of basic salts.

As regards the negative electrode, it is almost invariably assumed that only normal sulphate is produced during discharge, and yet it is here more especially that such an action is most difficult to understand, for, troublesome as it may be to oxidise lead sulphate, it is many times more troublesome to reduce it, except in almost infinitesimal quantities.

M. Darrieus has indeed recognised this difficulty, and endeavoured to explain it by propounding the theory that the formation of sulphate at the negative electrode takes place in two stages. First, suboxide of lead (Pb^2O) is formed, presumably at the expense of the water in the electrolyte—and then this

Digitized by Google

substance is acted upon by the acid, and converted into a mixture of normal lead sulphate and metallic lead, the latter serving as a nucleus to the former and not being further attacked; but such an explanation does not really advance matters any further than the simpler one given above, which assumes a direct formation of lead sulphate round a metallic nucleus.

Although such a suggestion does not before appear to have been made nor, indeed, such a compound isolated, yet it would be a real help in this connection to assume the formation of a sub-sulphate of lead (Pb^2SO^4) corresponding to the sub-oxide Pb^2O. This latter substance is with difficulty distinguished from a mixture of monoxide and metallic lead (in fact, it is described as such in some text-books) when under the action of chemical re-agents; and, in the same way, the sub-sulphate would act like a mixture of normal sulphate and metallic lead when subjected to analysis. It would, too, in all probability, have a considerable conductivity and, therefore, be easily reduced on charging, while its colour would no doubt be some shade of grey. "Sulphating" would consist in the conversion of a molecule of sub-sulphate into two molecules of normal sulphate,

$$Pb^2SO^4 + SO^4 = 2PbSO^4,$$

and only when this had taken place would it be possible for that formation of peroxide to begin which causes such a rapid drop of E.M.F.

Particulars are given in Prof. Ayrton's Paper as to the variations in hardness of the active material during discharge, and it will be found that while the positive paste became exceedingly hard, that at the negative gradually became softer, a fact which does not seem compatible with the formation of one and the same compound, *i.e.*, normal lead sulphate, at both electrodes, but rather favours the theories just given.

(To be concluded.)

NOTES ON ELECTRIC TRAMWAYS IN THE UNITED STATES AND CANADA.*

BY H. D. WILKINSON.

(Continued from page 703.)

This leads me to the question of the use of city water mains and gas pipes as return conductors. At Milwaukee, Wisconsin, where this was first brought under my observation, I was informed by the city engineer, Mr. G. H. Benzenberg, that considerable difficulty had been experienced. City water mains and service pipes had become corroded in from two to three years, the action being most marked near the power stations. An attempt was made by the passing of an ordinance to stop the tramway companies connecting their rails to any pipes whatever; but the matter had gone too far, and the benefit to the latter companies in reducing volt losses by so doing was so marked that the practice was still carried on in spite of this ordinance. The matter was at length remedied by obliging the companies to make good connections to the water mains at the nearest points to the power house where the current left the pipes, such connections being taken right on to the switchboard return. The point proved was that pipes were affected at points where the current left them, like anodes in an electrolyte, and that protection could be afforded by putting a conductor instead of the electrolyte to earth. In this way pipes in an affected district could be thoroughly protected, but at considerable expense. It was evidently better to put such conductors to the rails direct, and not connect to pipes at all.

I saw several specimens of lead and cast-iron pipes that had been corroded and cut out, and have reproduced a photograph of some of the larger pipes in Fig. 9. Mr. Benzenberg informed me that the matter was cropping up in several cities, and that at the meeting of the Association of Waterworks Engineers last September great prominence was given to the subject.

I was, unfortunately, unable to visit Boston and Cambridge and see the extensive electric tramway systems and the enormous power houses there; but, partly by communications with Mr. Morse, and partly from Boston engineers who visited the Exposition, I was informed of some of the experience gained on these points in those cities.

The amount of return current to deal with can be imagined when it is known that the West End Railroad Company have an output of 12,000 H.P. This is distributed from three stations, of which the one at East Cambridge alone has an output of 6,000 amperes. Considering, also, that of 270 miles of track more than half is of 56lb. and 70lb. rails, laid years ago, and either bonded indifferently or not at all, it is not surprising that pipes and cables which were metallically connected to the rails in places should be affected. The information I have from authentic sources is that the water and gas mains and lead-armoured telephone cables suffered to a very great extent. The Bell Telephone Company tried earthing their cables by connecting them to lead plates buried in manholes, but this afforded no protection from the very heavy currents passing.

A curious experience was gone through in this city in reversing the direction of current. The supplementary wires resorted to as a means of increasing the conductivity of the track became corroded to such an extent that when a car passed an affected section a difference of potential was set up between rails and earth sufficient to cause shocks to people and horses. This effect was so great towards the end of the year 1891 that the West End Railroad Company reversed their current, making the rails positive and the trolley wire negative. The current then left the station by the earth connection, including all piping in the station, and the condenser pipes were attacked. Other troubles arose at fresh points, where the current left the city pipes to get on to the rails, and to obviate these the current was again reversed, making the trolley

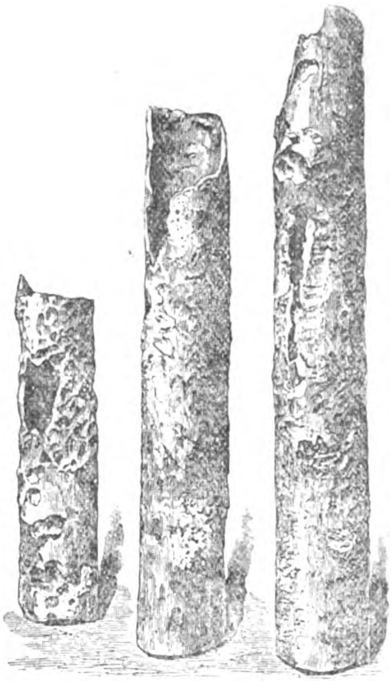

Fig. 9.

wires positive again. The action was then noticed in places near the power house where the current left the pipes, and this was overcome by making heavy copper connections to the pipes in these places, and carrying the same to the negative poles of the generators in the power house. It was also found that gas pipes had to be treated in the same manner, and soldered connections were made between gas and water pipes in all large buildings and in places in the streets.

Where the return currents reached 12,000 to 15,000 amperes the ground along the track was found to be heated, and return feeders from heavily loaded points had to be used. These were tapped down near the station to underground pipes, as it was found that if this was not done the pipes entering the station were at a difference of potential—sometimes as much as 5 volts—sufficient to heat an iron wire between them, with consequent danger of fire.

Mr. Morse, in a comprehensive Paper on this question before the New England Water Works Association at Boston, Mass., in January, 1893, describes having tried covering pipes with cracked stone, and in muddy places bedding them in cement, as a protection; but this was costly, and of no use unless done completely over the whole pipe system.

The trouble with electrolysis in this city I take to be due to the exceptionally large outputs and indifferently bonded rails. The city has purchased experience at heavy cost, but which has been of benefit to others. The adoption of return feeders and good bonding on later lines, with freedom from these troubles, has been one

* This Paper will be discussed early in the course of the next session of the Institution of Electrical Engineers.

Digitized by Google

result. At the same time the congested condition of current density has raised the question of some other means of distributing current to cars. One method about to be tried in Boston and Cambridge is the three-wire, or zone, system. The rail or earth return would then be the neutral wire, and the sections of trolley-wire would be alternately positive and negative. The section of the trolley and feed wires within a circle of, say, one mile of the power station would be at 500 volts positive potential, and the outer sections 500 volts negative. Further, this section might be again divided into half or quarter-mile zones, or further sub-divided, thus practically preventing any flow of current in the earth. By this means the potential and volume of current would be distributed more evenly over the circuit, and there would be less concentration of current at power houses. The current would return by the insulated feeders. On the other hand, there would be a current flowing through the rails or earth from the cars on one section to cars on another; but this would supply power to twice as many cars as on the two-wire system. On rare occasions, if all cars happened to be banked on one section or a set of sections at one potential, the action would be like a two-wire system, and the current return by rails and earth to the station. The spark, on passing an insulated junction between trolley wires of opposite potential, could easily be deadened by a small high-resistance shunt across the break. The general advantage of such a system cannot be pronounced upon until it has been tried; but, as far as the return current is concerned, it appears to offer considerable relief.

I should mention here that in Boston the experiment was tried of welding the fish-plates to the rails, thus making a permanent and reliable electrical joint. The Johnson Company, after obtaining good results on 3,000ft. of experimental track, were empowered to weld 16 miles for the West End Street Railroad Company, and during two years the rails have shown no tendency to buckle. During this winter, however, I learn that the rails have broken into sections of a few hundred feet, due to contraction, the fractures always occurring near the weld. I believe, however, that this is the right method, and may still be modified to give successful results. The bond should be made outside the fish-plates, allowing a loop for contraction, and the poles of the welder should be arranged to distribute the heat gradually from the weld, and so prevent abnormal strain of the metal. The absence of dissimilar metals in the joint ensures its permanency as long as the rail itself lasts, both as regards local action and expansion.

Reviewing the circumstances attending electrolytic action, as far as I have been able to gain information on the spot, I find that these troubles have chiefly been traced to insufficient conductivity at the rail joints, and to the want of proper return conductivity in the shape of feeders. When traffic on the lines increases, or extensions take place, and the increased power is drawn from the same supply station, either the bonds must be increased in sectional area (if they have not been put in at first of sufficient size for ultimate demands), or return feeders must be run to relieve the bonds, otherwise the consequence will be that the current will be crowded out of the rails into the earth. This is what has actually taken place on some systems in the States, and the current has been allowed to take its own course until the heating of rail joints and bonds has drawn attention to the want of conductivity. This crowding out occurs on the main or trunk lines, into which several branch lines converge. On simple lines, or those from which no branch lines radiate, it is less liable to occur, as even with an excessive volt loss per mile the density of current is well within the capacity of ordinary single bonds. Take, for instance, a line of three miles of double track between A and B (Fig. 10), and consider it first with no branch lines. Say we have a three-minute service of cars, and the average speed, allowing for stoppages, is $7\frac{1}{2}$ miles per hour. The cars will then be three-eighths of a mile apart, and there will be eight cars on each track. With two motors per car the current will be about 25 amperes at maximum speed; but some cars will be starting, and using 100 amperes, and we may take a time average right through of 50 amperes per car. The maximum current returning to the power station from A will then be 800, and the maximum at B 100 amperes. The resistance of copper bonds varies according to method of bonding, length and size of bond wire, and whether it is double or single. Per mile run of rail the bonds may be from one-sixth to twice or three times the resistance of the rail. Taking a 70lb. rail with low-resistance bonds, say of No. 000 gauge, 12in. long, and fixed double, we shall have the resistances per mile of rail 0·0344 ohm of bonds (176 to the mile) 0·0056 ohm—total, 0·04 ohm, or 0·01 ohm for the double track. The voltage loss will therefore be 1 volt per mile per 100 amperes. Working this out for the varying strength of current on different portions of the return, we have a loss of 10 volts on $1\frac{1}{2}$ miles from A to P, and 4 volts on an equal distance from P to B—total, 14 volts.

Suppose, now, a branch line is laid from P to C, also of $1\frac{1}{2}$ miles, with cars at same speed, and same rate of service. This will then absorb 4 volts, but the loss between P and A on the trunk line will be increased to 19 volts; and if another similar branch, P to D, is added, the loss on the trunk line becomes 28 volts, or a total of 32 volts on the whole. When it is considered that with a theoretical continuous rail without bonds this loss is only reduced by 5 volts, it will be seen that to prevent waste of energy, quite apart from reducing current density, we must connect return feeders to the rails on the trunk line.

Now, considering the current density, we have in the trunk line, when the two branches are in operation, a current of 1,300 amperes at P and 2,400 amperes at A. The maximum current per rail is therefore 600 amperes, and this on 7 sq. in. gives a density of 86 amperes per square inch of rail (equivalent to 510 amperes per square inch of copper). This could be increased four or five times before any sensible rise of temperature would take place in the rail; but, considering the bonds, whose sectional area per rail is 0·262 sq. in., we find we have a density of 2,290 amperes per square inch. It would probably take very little increase of current beyond this to cause heating of the bonds and crowding out of current into the earth; and yet the bonds on many lines in the States have less sectional area than the one cited, and the currents are from twice to four or five times as great, producing far higher densities in the bonds than they can carry. I am convinced that this is the cause of most of the electrolytic troubles in the States. Trunk lines, into which a number of branch suburban lines feed, are frequently of considerable length, and cars necessarily move slower in consequence of their accumulation on one line. Not only on account of the number of cars, but also because of their slower speed and frequent restarting, the current put on to the rails is very much increased, and the density in the bonds becomes far more than they can carry. We have seen that it is not a question of resistance or conductivity of the bond, as the voltage loss beyond that on a perfectly continuous rail is only increased by about one-sixth of that lost on the rail, and therefore the increasing of the conductivity confers no appreciable benefit so far as reducing voltage is concerned. The question is one of sectional area of bond with reference to the ultimate maximum current it is expected to carry, and this, I think, should not exceed 2,000 amperes per square inch.

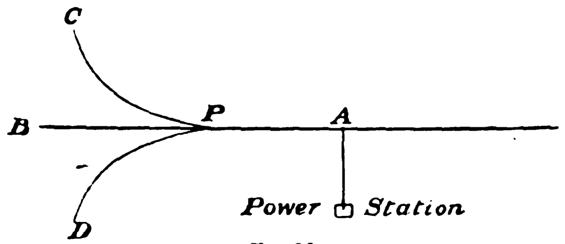

Fig. 10.

The sectional area of the bond refers as much to those portions in contact with the rail at the joint or joints, as to that of the single or double-bond wire itself.

I cannot leave this portion of my Paper without a tribute to the pioneer work and enterprise of our transatlantic cousins. They meet every difficult squarely in the face, and in spite of all obstacles "get there all the same." Our designs must necessarily comply with more conditions than are exacted in America; but when our difficulties have been the same our friends have generously been ever ready to impart their experience.

I will only touch upon one of the Board of Trade Regulations, viz., rule 7, similar to which is rule 9 of the Draft Regulations for Underground Electric Railways. In its draft form rule 7 exacted that the original or recorded resistance of the return should be maintained constant, with a maximum allowable increase of 15 per cent. In its amended form the same idea is carried out; but the element of current strength is included, namely, the product of resistance with current—that is, the difference of potential between extreme ends of the line—and this must not exceed 7 volts. The framing of the rule, I take it, was aimed at securing a low density of current in the rail, thus preventing the crowding out of which I have spoken, and placing the pipes of gas and water companies beyond all harm. It seems to me that this end is not altogether accomplished, because with a given difference of potential, however low, it is possible to have a very high density in the bonds, with a very low one in the rails. In other words, under complete compliance with the rule the bonds may be carrying far too high a density and shedding their current into the earth. Referring for a moment to the example considered above, a heavier rail might be laid with bonds of less sectional area and still not alter the difference of potential at the ends of the uninsulated return. A 90lb. rail would have 0·0268 ohm per mile—that is, 0·0076 less than the 70lb. rail—and this difference could be made up of smaller bonds of less carrying capacity. By using single bonds of No. 00 gauge (0·104 square inch section) instead of double of No. 000 (0·131 square inch section), this is obtained very closely, and we have the resistance per mile of rail 0·0268 ohm, of bonds 0·0142—total, 0·0410, or 0·01

Digitized by Google

ohm for the double track, as before. The difference of potential at the ends of the uninsulated return for the same currents is, therefore, unchanged; but the densities are very different. That in the rail is reduced to 66 amperes per square inch (equivalent to 400 amperes per square inch of copper), while that in the bonds is increased to 5,760 amperes per square inch—nearly three times more than the limit I alluded to. Some of this density is relieved, of course, by the conductivity of the fish-plates; but this is of such a variable and unreliable nature that it should not be reckoned upon. Density, of course, can and should be relieved by return feeders, and these would be necessary on most lines of any extent to keep the volt loss within the required limit; but even with return feeders and low density in the rails I have shown that there might still be too great a density in the bonds, if these were not of sufficient section. Further, it appears to me that a limit of volts per mile would be equally effectual and more workable than a certain limit for lines of all lengths and traffic.

Having endeavoured to put before you the results of my observations, I may say that I am convinced that bonds should be of sectional area proportioned to load, which will materially lessen cost of return feeders; and, secondly, at points on the rails chosen with regard to load, return feeders should be connected of such section as to relieve the density of current in the rail. By return feeders I do not mean supplementary wires or connections to water pipes, but metallic conductors either above or below ground; not necessarily insulated, but connected direct from the rails to the power station. Supplementary wires are of no use unless increased in section as the current increases, so as to keep an approximately constant density, and this I have never seen done; while making connections to water pipes is a makeshift at best, and one that shows a want of good design. I believe that by designing the return circuit of electric tramways in the manner I have indicated we shall keep clear of electrolytic troubles upon gas and water pipes, and ensure an unhandicapped career for electric traction in this country.

I now come to systems in which the return is insulated from earth; namely, those using the overhead double trolley and the underground conduit. I was much interested in the double-trolley system working in the city of Cincinnati, Ohio, and wished to ascertain whether the insulation from earth was well maintained, and of sufficient benefit to warrant the use of such a system. I received the greatest courtesy during my stay in that city from Mr. George Hornung, civil engineer; Mr. H. P. Bradford, of the Cincinnati Inclined Plane Railway Company (using single trolley); Mr. Kilgour, of the Consolidated Street Railway Company (using double trolley); and Mr. Wm. J. Clark, of the General Electric Company, with whom I visited the power houses and inspected the lines. I shall not easily forget my first impressions of double-trolley working, as I passed through Fourth-street to Fountain-square, in the busiest part of this city, on the morning after my aarival; cable cars, double and single-trolley cars, and horse cars followed each other in rapid succession, often on the same track; but the most startling thing was the immense amount of trolley and span wires suspended over the roadways, with all the necessary adjuncts of insulators, guard wires, frogs, and separators. I watched several of the double-trolley cars rounding curves, and observed that the trolleys frequently jumped off the wires, and that the conductor on the car had to keep his eyes on the trolleys and steer them with the cord on passing curves.

A good deal of extra complication was due to the presence of single-trolley wires along double-trolley tracks, and the necessary use of span wires in the narrow streets of the city. Out in the suburbs, however, the double-trolley construction was seen to better advantage, as the wide roads allowed for centre-pole construction. The rumour prevailed in other cities that the double-trolley system was on its last legs; but, so far from that being the case, I found that the Board of Affairs of the city had just granted the Company powers to lay 50 additional miles of double-trolley track, the mileage then in operation being about the same in extent. No doubt the rumour arose from the fact that this was the only city in the States (with the exception, I believe, of a small line at Rochester) that employed the system, and the history of its rise in Cincinnati was remarkable. The first to be put down was a single-trolley line, which was opposed by the telephone company on the ground of interference. Litigation resulted in favour of the latter company; but the tramway company appealed on two or three judgments to higher courts, and eventually got a verdict in their favour. During the progress of this litigation a new tramway company was financed by those most largely interested in the telephone company, with the view of proving that double-trolley was the only way out of telephone interference, and to force the hands of the single-trolley company. Mishaps in winter, however, in the earliest days of its adoption, favoured the final appeal above alluded to, and ended in metallic returns being put on telephone lines instead. The position remains unaltered to-day, and both trolley systems prosper.

I found that the insulation of the double-trolley lines was good, so far as the overhead construction was concerned; but that it frequently broke down at the motors, thus putting one or other trolley line to earth. To show what kind of insulation existed, my friends and I boarded a single-trolley car, stopped it, and pulled the trolley arm off the single wire on to one of the double-trolley wires; the lamps lit up inside the car showing an earth on one main of about 200 volts. The leak was not sufficient, however, to run the car, but it appeared that in wet weather this was frequently done. Again, in the Hunt-street station, an earth indicator was permanently fixed, consisting of two rows of five lamps, in series. Each row was connected between one of the trolley wires and earth, and I observed during my visit to this station that one of these rows was lighted up to nearly full candle-power. The light was fluctuating slightly, which appeared to indicate that the earth was on a moving car; at all events, I was informed that such earths were of frequent occurrence, and went off as suddenly as they came on, but did not affect good working. Earths on a line were "spotted" after all cars were home for the night by switching off one section after another while full power was kept on. The leakage current on two lengths of twelve and nine miles of double track joined in multiple with all cars off, was 12 amperes, under the full pressure of 500 volts.

The cost of street work in America for double-trolley construction is about £650 per mile, the items being as follows:—

	£	s.	d.
100 iron poles	£260	0	0
100 hangers	17	0	0
100 solder cars	5	0	0
70 strain insulators	4	9	8
3,000 feet span wire	12	0	0
10,560 feet No. 1 copper trolley wire	84	9	8
5,280 feet No. 0000 feed wire	211	4	0
25 3-foot cross arms	0	15	0
50 glass insulators	0	12	0
200 sacks of cement	12	0	0
15 loads broken stone	4	10	0
5 loads sand	0	15	0
Labour and superintendence	45	0	0
	£657	15	4

This is about one-third more than the cost of single-trolley construction; but against this must be put the dispensing with bonds.

While this system is out of place in cities and confined thoroughfares, and, indeed, wherever span wires must be used, I believe it offers some advantages for heavy passenger traffic or goods traffic in suburban districts. It offers immunity from leakage currents to earth, for such can only take place when more than one earth is on the line. There is, therefore, no anxiety as to electrolytic action on pipes, even with the heaviest currents, no interference with telephones, and it is not necessary to bond the rails. With neat iron poles and ornamental cross brackets the line is not at all unsightly in the centre of the road. On some lines the appearance is improved by clusters of incandescent lamps, with reflectors, on every second or third post, and all feeder cables kept underground. The only objection to the system is the amount of overhead work at curves, turn-outs, and crossings; but it certainly holds its own in Cincinnati for smooth and rapid transit, and has proved itself a commercial success. On the table are some photos of the city for members to examine, showing some of the overhead construction. I have here also a specimen of the Kisinger splicing tube, by which breakages in trolley wires are rapidly repaired (Fig. 11). I witnessed two breakages in one street, which took only five minutes each to repair by means of these tubes. The broken ends are pulled up and put in the tube, and then the dogs slipped in through the slot. When the tackle is slacked off the ends are locked, and an excellent electrical joint made without soldering. For working at the wires an emergency waggon with folding ladder is used, and joints have been made in 3½ minutes, including picking up broken ends from the street.

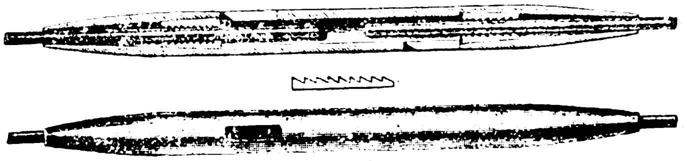

Fig. 11.

I now pass to the consideration of underground conduit lines, also using an insulated return.

During my stay in Chicago, the extensive plant of the North Side Tramway Company, consisting of gas motors fixed to special cars, suffered almost complete destruction by fire. As there had been serious complaints of the noise and smell of these gas motors, the Company endeavoured to get a clause revoked in their franchise which prohibited their using an overhead trolley line. Their intention to equip their line in this manner, however, met with

Digitized by Google

great opposition from property holders, tradesmen, and insurance companies, and the clause was not struck out by the City Council. Previously, however (in March, 1892), in consequence of this clause, the Company had equipped about a mile and a quarter of their line electrically with an underground conduit on the Love system. I found this in successful operation last year, and made a few notes on it, which, I hope, may prove of interest. The illustrations (Figs. 12 and 13) show sections of the line construction and roadway. The depth excavated below the road level is only

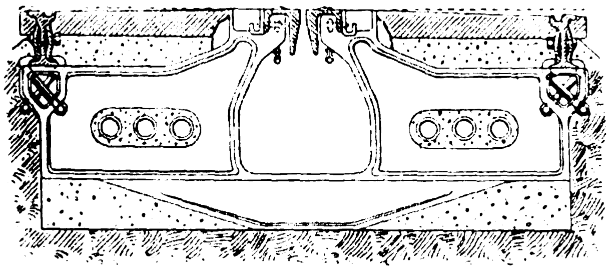

FIG. 12.—Yoke.

2ft., involving no trouble or expense while laying the track in diverting pipes along the route, as is so often necessary in laying a cable track.

The slot rails are in 32ft. lengths, and bolted to the yokes every 4ft. Pockets, or small hand holes, are provided in the road over every bolt, so that, if required, the rails can quickly be removed, and the conductors and insulators exposed to view. The slot rails are spaced for a ⅝in. slot, and shaped with 5in. inside lips, so as to shed water into the conduit clear of the wires. The track rails are held by claw bolts to the yokes, as shown, and the whole construc-

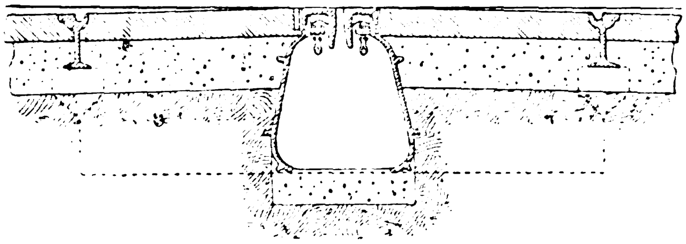

FIG. 13.—Conduit.

tion rests on a bed of 6in. concrete, and is packed round with concrete as a bed for the stone blocks of the roadway. In the webs of the yokes spaces are left for laying pipes to contain feeder wires, the conductors being in sections of 500ft. The conductors are of bare copper rod, nearly half an inch diameter, grooved longitudinally, and suspended from loose-fitting gun-metal clips, or ears, as shown (Fig. 14). The stalk of each clip is secured to a block of pressed mica or other insulating material, B, which is suspended from two shoulder bolts bolted to the yoke. To allow for expansion of the conductors, the blocks are free to move about 2½in. on the

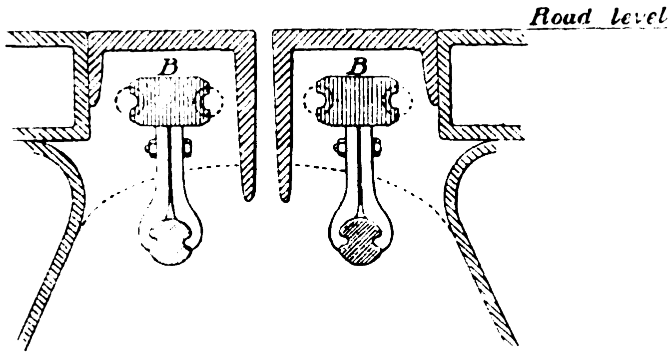

FIG. 14.

rods. With the trolley wheels travelling in the direction of the arrow, it was found that the blocks shifted a little in the reverse direction every time the trolley wheels passed, and it was necessary to put stops at S (Fig. 15). The insulators are fixed to every alternate yoke, at a distance apart of 9ft. on the straight run. On curves, however, they are closer together, and stronger supports are used, the conductor being circular in section, and clipped in ears having circular jaws, as shown in Fig. 16, which are afterwards filed round below, so as to offer no resistance to the trolley wheel.

The trolley wheels bear upwards on the underneath side of the conductor, exactly as in overhead lines. The illustration (Fig. 17) shows the arrangement with spring for keeping tension on trolley wire, and back stop for keeping the wheel in place on the wire. The plate travelling in the slot and supporting this gear is of ½in. steel, and 4½in. wide. The trolley arms are jointed to take lateral as well as vertical movement, and thus follow every change of direction of the conductors.

The line in Chicago is in the form of a triangle a little over 1¼ miles long, with three straight lengths and three curves, and in one place it crosses over the cable line. The motor cars (which also carry passengers) haul the trailers with passengers left by the Lincoln-avenue cable cars and North Halstead-street horse cars round Fullerton and Webster avenues. This was the first line on this system, and, as might be expected, some difficulties were met

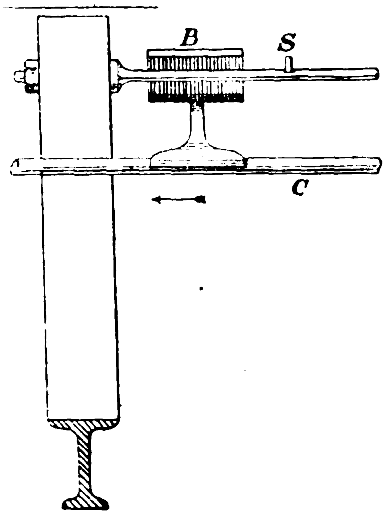

FIG. 15.

with. These were chiefly due to the breakage of insulators, expansion of conductors, and snow and ice in the conduit. Boys were also a nuisance, stuffing wire into slot, which jammed the trolley wheels and short-circuited. I found that in July last there had been five stoppages, two in August, and none at all the following three months. Two of the stoppages were, however, due to burnt-out armatures. Brushes were used attached to cars for sweeping out water and dirt from the conduits into sump-holes every 100ft., which were afterwards pumped out by hand. Water gave no trouble at all, except when it froze in the conduit. Wide extremes of temperature are met with in Chicago, being 15° to 20° below zero in the winter, to 90° in the shade in the summer, and expansion gave a good deal of trouble at first, especially at curves, where the conductors sagged till they nearly touched the side of the iron conduit, upon which the trolleys made earth and short-circuit by touching the sides. This was overcome by dividing the conductors

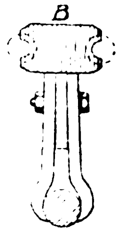

FIG. 16.

into sections of 500ft. to 600ft., and covering the adjacent ends with a long sleeve. Powerful compressed springs on either side of the sleeve were used as shown in the illustration (Fig. 18), which drew the ends together and took up the expansion.

At the Milwaukee Convention Mr. M. D. Law read a Paper on this system as now operated in the city of Washington (district of Columbia), in which he mentioned the improvements introduced by the Rock Creek Railway Company using the system in that city. I subsequently saw this line at Washington, and found the construction perfected in many details, and the system giving completely satisfactory service, uninterrupted since its inauguration in March, 1892. The line was a credit to this well laid out city, and anyone who could see the smooth and regular running of the cars, with no overhead wires, would say there was a great future for such a system in city traffic. The line of the above Company extends some 6½ miles in the suburbs with the overhead trolley system, but at the city boundary it changes

Digitized by Google

to underground trolley. The change from one to the other only involves fixing the trolley bar, and switching off the earth connection, which I timed to take 20secs. The line then continues along U-street for 1½ miles with double track. On the return journey, close to the junction, the cars have to take a sharp curve, and take an ascent of 1 in 40 at the same time, which they do easily. The insulators and supports at the curves are all strengthened, and the conduit is made 20in. deep by 14in. wide, the extra width allowing ample clearance between the wires and the sides of the conduit. The yokes are also put at 4ft. centres instead of 4ft. 6in., and the conductors are of ⅝in. hard-drawn copper. A separate power house was erected to supply the underground system, as it was desired by Mr. Law and Mr. Herbert Claude, the engineers to the Company, to thoroughly test the system. Leakage to earth, as shown by a voltmeter between the conductor and earth, was only 0·1 per cent. even in the stormiest weather, and the ammeter remained dead at zero when the full E.M F. was on and the cars all off. In the wettest weather it was a common thing to

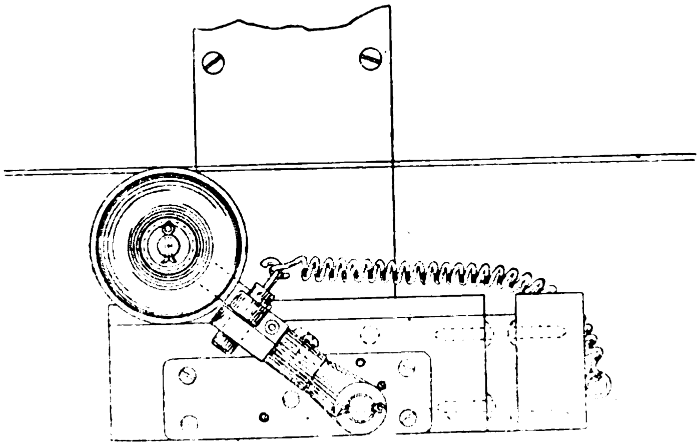

Fig. 17.

find dusty insulators and perfectly dry conductors on removing the slot rails, this condition being due to the natural draught in the conduit and the umbrella nature of the slot rails. On two or three occasions, however, severe rain storms had flooded the conduit and immersed the wires; but the cars ran without delay. With four fully-loaded cars on the line the drop was only 3 volts. The trolley wires were in sections, with main and return feeders, switches, and cut-outs to each section, placed in manholes every 500ft. on the straight run.

I have here copies of two Bills which have recently passed the House of Representatives, authorising an extension of tramways in the city of Washington, in which the system of underground conduit I have just described is to be used. The section of the Act incorporating the Washington Traction Company which refers to the system reads as follows:—

Sec. 2. "That the motor power shall be the underground electric, such as is now in use on the U-street branch of the Rock Creek Railway, on all of its road east of Rock Creek, while the

B B = Insulating Blocks or Carriers with Grooves, riding loose on Upper Rod, and gripping Copper Conductor as shown in end elevation at B B, Fig. 14. G = Slipper Grip fast on Conductor, but loose on Rod above.

overhead trolley shall be used upon that part of the route northwest of Rock Creek *until such territory shall be built up* and the District Commissioners shall deem it proper that the wires shall be placed underground."

The other Act empowers the Brightwood Railway Company of this city to extend their lines within the city, using the above system.

It has been proposed to use synchronous, two-phase, or three-phase motors for tram-cars, chiefly with a view to economy in the transmission of energy, but also with the object of avoiding electrolytic troubles. There are advantages to be considered in the use of alternating currents, but it would involve the carrying of line and return close together in the neighbourhood of telephone lines. A tram-car fitted with a three-phase motor, said to be the first one so fitted, was exhibited by Messrs. Siemens and Halske in the Electricity Building at the World's Fair. The motor was four-pole, of 20-H.P. nominal, but capable of working up to 60 H.P. at 500 to 600 volts and 1,400 revolutions. The reduction gear was enclosed in oil.

I now come to some points in power house plant. Most of the stations I visited had large cross or tandem compound horizontal condensing engines, the average units being of 500 H.P., driving 200-kilowatt generators by belts. These were usually compound machines, to give 500 volts on open circuit to 550 on full load, and had the intermediate connection taken from the brushes to the switchboard for coupling machines in parallel. In allowing for "drop" a good deal depends upon the site of the power house. In the heart of a city, where there are a large number of pedestrians and vehicles, the cars must of necessity travel at slow speed, and do not, therefore, require the full pressure, while in the suburbs speed is a matter of importance for business men coming into and leaving the city; and in Cincinnati it was particularly necessary to keep the pressure up, owing to the hilly nature of the suburbs. The power houses, I found, were built in the suburbs in situations most suitable to deliver highest pressure where most required. Short circuits being of very frequent occurrence, magnetic cut-outs were placed on the feeder and dynamo mains at the switchboard, and in some cases on the machines as well.

With built-up flywheels of the ordinary type it is well known that the maximum linear speed of the rim must not exceed a certain limit of, say, 6,000ft. per minute. Centrifugal force, acting radially outwards, tends to bend those portions of the rim lying between spokes, putting the outside of the rim in tension, and the inside in compression. What the stresses due to bending actually are need not be gone into here, but it is evident that the safe factor between bending moment and circumferential tension of the rim rapidly diminishes as the limiting velocity is exceed, and from this cause wheels occasionally fly to pieces without any previous warning. The large amount of energy stored in these 25ft. and 30ft. flywheels answered the purpose of keeping the volts up under sudden increase of load, but were somewhat a cause of anxiety when short-circuits came on. Either the magnetic cut-out did not act quickly enough, and the inertia of the driving power kept the dynamo up to speed, and forced it to a burn-out, or the engine raced to a dangerous extent on the quick withdrawal of full load. Some instances of these came under my own observation. At the Hunt-street power-house in Cincinnati, where there are intermediate lines of countershafting between engines and dynamos, I noticed some repairs being effected, and was informed that seven pulleys on one line of countershafting had flown to pieces on the occasion of one main engine racing, and that the broken pulleys had smashed an equivalent number of dynamos which they were driving. I was then shown an ingenious arrangement that had since been added to the Corliss cut-off gear, in preparation for the next occasion of racing, by which steam could be instantly cut off the engines by pulling a cord which came over a pulley on the ceiling. These cords were dropped down at various points in the station, so that a man, say at the switchboard, could instantly stop any engine. Pulling the cord released a weighted lever, which moved a cam into such a position under the trip gear that steam was completely shut off during the whole of the stroke. At the time of my visit to the Atlantic-avenue Street Railroad power house in Brooklyn broken parts of one of the large fly-wheels, together with a generator, were just then being taken out through an opening in the station wall, which, with part of the roof, had been demolished by the flying pieces of a racing engine. The facts were fully reported in the American Press at the time, and the engineer in charge was highly spoken of for the manner in which he endeavoured to avert the catastrophe. On account of the uncertainty of cut-outs it was generally considered that the generators should be under-engined, thus allowing a margin for overload.

(*To be concluded.*)

ELECTRIC POWER IN FACTORIES.*

Closely associated as I have been all my life with an engineering works started more than half a century ago, and increasing in size with the growth of the trade of the district until it has become one of the largest marine engine works on the North-East Coast, I have had by tradition and experience continually before me the difficulty of always keeping up to date with machinery and meeting the demands of labour, and, great as this task often has been in the past, I can recall no time so discouraging and difficult as the present. We have had to contend with bad trade, with disputes between capital and labour; but I remember no period when we

* Abstract of Presidential Address delivered before the North-East Coast Institution of Engineers and Shipbuilders by Thomas Richardson, B.A.

Digitized by Google

have had pressure from both troubles to contend with at the same time, making the successful carrying on of industrial concerns an impossibility. Those of you who are directly associated with the engineering and shipbuilding industries will readily appreciate that the subject of economical production is one to which more than usual prominence has lately been given by the recent almost complete stoppage of work on this coast, by one of those disastrous disputes between capital and labour which are now so frequent. Another factor which is year by year becoming more prominent is the competition of foreign countries, and the unfortunate doctrine which is so often sensationally made use of as to our superior capacity as handicraftsmen is by no means so true now as formerly. The extended and universal adoption of machinery has been the chief cause of this levelling up; and particularly is this the case in the engineering industry, where the scope for the application of machinery is practically unlimited. It is not enough, however, to apply machinery, but to develop it, as the one remedy for survival is continuous evolution; although the unconscious fascination, which is often associated with old tools and old methods, often renders the evolution dangerously intermittent. It is apparently this fascination, combined with an unselfish desire to satisfy the cravings of the shipowner for propelling machinery requiring the least possible consumption of coal, which is responsib'e for the fact that, whilst we build engines and boilers consuming 1½lb. of coal per indicated horse-power per hour, we drive the machinery in our workshops at an expenditure of fuel four to six times greater in amount. This is, of course, attributable to the use of a number of high-pressure non-condensing engines distributed over a large area, and supplied with steam through long lengths of piping from a central group of boilers. This, then, is a field in which economies are to be obtained, and one of the best solutions appears to be the application of electrical driving.

In the able address of Prof. Kennedy before the Institution of Mechanical Engineers this subject was very fully dealt with, and at the late meeting of the Iron and Steel Institute of Brussels a very interesting and instructive Paper was given by Mr. Selby Bigge, which conclusively showed the importance and possibilities of the system. At the risk of rendering this address narrow, and more in the form of a Paper, rather than general, I propose to give some illustrations of the application of electrical driving, both in this country and abroad, hoping that a *résumé* of what has actually been accomplished may promote a discussion which will thoroughly ventilate the question and be fruitful in beneficial results. With the late disastrous record of the shipbuilding and engineering industries as an example, it is highly improbable that any capitalist will start a new shipyard amongst us, so that we may be sufficiently selfish to consider the application of electrical driving to existing works only. The first question to consider, therefore, is that, having boilers grouped in one place from which steam is led to engines distributed over a large area, what economy can be expected from substituting those engines with electric motors supplied with power from a central station, and will the results justify the expenditure? We are all thoroughly aware that condensation does occur in steam pipes, and that the present engines are uneconomical, but a broad view is generally taken of the matter, and little has been done to ascertain what the results really are. It is for this reason that the experiments and developments made by Mr. Panton, of Messrs. Dorman, Long, and Co., of Middlesbrough, in conjunction with Mr. Selby Bigge, are of the greatest value, and particularly so as they have resulted in complete success. The original steam-driven machinery comprised punching, shearing and bending machines, cold saws, &c., all of which were distributed over a large area and driven by six engines capable of indicating the following powers, viz. :—27, 14, 14, 14, 16, and 9. These engines were disconnected and replaced by motors of 10½, 3½, 5, 3½, 3½, and 3½ H.P. respectively, the driving gear consisting of a belt from the motor direct to the flywheel of the machine. The most noticeable case is where a large bending machine formerly driven by an engine having a cylinder 10in. diameter, with a stroke of 12in., is now efficiently worked by a 3½-H.P. electric motor. The current for these motors is generated by a 50-H.P. Pieper dynamo driven by an ordinary horizontal engine, the steam being obtained from two Lancashire boilers which were already in use in connection with the steam driving of another portion of the works. Formerly the six engines in question were supplied with steam by two boilers, which are now dismantled, with the result of a net saving of 30 tons of coal per week and the entire labour in connection with stoking and upkeep.

Another striking advantage is that, the speed of the motors being practically constant under all loads within their capacity, the machines driven by them are always running at the desired speed, and are, therefore, in a condition for producing the greatest possible amount of work. In reviewing this plant we have the advantage of ascertaining the approximate loss resulting from condensation in a long range of steam pipes, and the working of small high-pressure engines under conditions usually found in ironworks and shipyards. It will be apparent, however, that the generation of power at one centre admits of an economy beyond this; viz., the use of a modern high-pressure triple-expansion condensing engine, with a consumption of 12lb. to 14lb. of steam per indicated horse-power per hour, instead of a consumption of from 40lb. to 60lb., as frequently is the case at present. It is evident that the loss in such a case as that of Messrs. Dorman, Long and Co. may be termed a maximum, on account of the machines working in the open air; and the steam pipes led underground; but the results from ordinary cases of shop machinery are often sufficiently startling to warrant more attention being given to them than they usually receive. For purposes of comparison we will consider the results obtained from two works of about equal driving power, one having an electric installation and the other steam.

One of the most complete installations of electrical driving in the world as applied to large industrial establishments is that of the National Arms Factory at Liége, Belgium. These works were built in the year 1889, and are of very large extent, employing 2,000 hands, the daily output of finished rifles being 250. Some idea of the system adopted, and the value of machinery for economical and rapid production, may be formed when it is considered that there are about 58 parts in a complete rifle and bayonet, involving in their production about 750 operations; yet so great has been the development of machine tools used in this manufacture that, of the 750 total operations, only 6 per cent. are performed by hand labour. Another feature is that a large percentage of the machines are automatic, and advantage is taken of this by placing several in the charge of one operative.

The whole of the machinery is driven by electric motors receiving their current from one central dynamo coupled direct to a Corliss condensing compound engine having two cylinders and indicating 500 H.P. at 70 revolutions per minute, with a boiler pressure of 90lb. The auxiliary feed and condensing water is supplied by a pump driven by a 10-H.P. motor, receiving its current from the main generating dynamo, and placed on the canal bank 2,840ft. distant and 117ft. below the level of the engine. The water, after being used in the condenser, is discharged into a tank placed 40ft. high, from which it passes through finely perforated pipes in the form of spray into an open reservoir on the ground level, and by this means is reduced in temperature so as to be again available for condensing purposes. The generating dynamo is placed between the high-pressure and low-pressure engines, and the armature, being on the main shaft, acts as a flywheel. The armature, which is 16ft. in diameter, was constructed in place. The electromagnets are 20 in number, and there are 40 pairs of brushes, 20 on each side. The capacity of the dynamo is 3,000 amperes at 125 volts, and the makers guaranteed an efficiency of 90 per cent. The current from this powerful generator is distributed to about 31 motors, ranging from 3 to 50 H.P., placed in different sections of the works. The machines used in the manufacture of rifles are necessarily of light design; consequently the motors are arranged to drive line shafting only, and although the total length of main shafting exceeds 4,000ft. and the total length of belting is about 11 miles, there are no indirect main drives, a motor driving one line of shafting only, the object in view always being the reduction of loss by friction.

Each motor is provided with an ammeter, and as those in charge know the amount of power required to drive the machines when being worked to their desired capacity, any increase of that power at once indicates that there is a waste in friction, whilst any decrease indicates that the machines are not doing sufficient work; and when it is remembered that the revolutions of the motor are practically constant under all loads within their capacity, it is impossible to imagine an arrangement which so exactly fulfils the requirements of maximum economical reduction.

Compare this with the wasteful arrangements so common in shipyards and engine works, where engines, often already fully loaded, have to drive still another new tool, and the "make-the-best-of-it" policy of giving just a little later cut-off is adopted. The result generally is that the mean revolutions of the main shaft are not only decreased by any variation in load, but are, in addition, highly sensitive to the variations of steam pressure. This is, however, a diversion, and referring again to the Liége factory, there is also a 300-H.P. Willans engine, coupled direct to a dynamo, which generates the current necessary for recent extensions.

It has been found by careful experiment that the consumption of steam in the Corliss engine is about 14lb. per indicated horse-power per hour, whilst the losses are 10 per cent. in engine friction, 10 per cent. in the dynamo, 2 per cent. in lines, and 15 per cent. in motors, or a total efficiency of 63 per cent. at the motor, driving pulleys of the indicated power of the generating engine. The whole of the electric installation was made and fitted by the International Electrical Company of Liége from the designs and under the direct superintendence of Mr. H. Pieper, the managing director and electrician-in-chief of the Company, and we have an ample testimony of the efficiency of the entire plant in the fact that, although the works have been running over three years and

Digitized by Google

a-half, there has not been one single stoppage of the main dynamo during working hours, and no accidents of any kind whatever.

Particulars such as these are always of general interest, but any radical change made in existing works involves a very considerable outlay, and extreme care is necessary to be certain that such a change would be commercially successful. It is, therefore, essential in the first instance to ascertain what are the conditions existing at present; so we will take as an example an average old-established marine engine works, of which there are many in this district, the majority of them having been added to year by year to meet the demands of trade, and where extensions have generally been the result of a compromise between what was desired and what existing conditions would allow.

The works in question are steam driven, the boilers being arranged in one group, and supply steam at 60lb. pressure to 31 engines in different parts of the works. Eight of these are used for driving the machinery in the various sections of the works, and 23 are auxiliaries in connection with cranes, hydraulic pumps, and the like. The driving engines are of various powers and of designs which may be taken as representing a fair average of those used for the same purpose in similar works.

„ 8.	15·6	7·8	1,068	75	700	45·0	840	53·8	58·5

No. 1 is a beam engine fifty years old, and is used for driving about 50 lathes, planing, slotting, and drilling machines of various sizes. With an average daily working load the indicated horse-power is 48, whilst running the shafting only, and with the machines all standing it is 17. Steam is supplied through 680ft. of piping, and the water discharged from an automatic steam trap close to the engine stop-valve amounts to 270lb. per hour. The weight of steam used by the engine and as measured from the diagrams at the average daily load, viz., 48, is 2,227lb. per hour, to which should be added 20 per cent. for moisture in suspension, thus making a total, including the water condensed in the steam pipe, of 61lb. per indicated horse-power per hour. No. 2 engine is a modern two-cylinder horizontal, with variable expansion gear worked by the governor. The machines driven consist of two dynamos for works lighting, as well as a large number of average-sized tools.

It will be seen from the table that the average working load when driving the dynamos is 93·8 H.P., but driving during the day the average horse-power is reduced to 38.

Nos. 3 and 4 are single cylinder inverted machines, and afford a good example of the wasteful effects of overloading.

Nos. 5 and 6 are old-fashioned horizontal engines, in which the governor works an ordinary throttle valve, and both have been in use for about thirty years.

Nos. 7 and 8 are small inverted cylinder vertical engines running at 150 revolutions.

The wasteful effect of this system of driving is shown by the consumption of steam, which averages 50·9lb. per indicated horse-power per hour, and to this has to be added the condensation in the steam pipes, which is 7 per cent., bringing the total up to about 55lb. per indicated horse-power per hour, and even this is by no means exaggerated, as it is probable that the condensation in the pipes exceeds that indicated by the traps. In comparing the two systems at this stage, and allowing 10 per cent. for engine friction in each case, and a total electric loss of 27 per cent. for dynamo conductors and motors, we require 45lb. of steam per effective horse-power at the main driving pulley of the steam installation against about 20lb. for the electric. Taking the total at 500 effective horse-power (which allows 125 average for the 23 auxiliaries) in each case, and an evaporation of 8lb. of water per pound of coal, the consumption of coal would be 36 tons per day for the steam and about 13 tons for the electric. In the steam installation under consideration the water is obtained from the waterworks main at considerable cost; whereas under similar conditions, with a condensing engine, the cost would be much less.

Another feature of value is the reduction of labour, which for stoking alone would be about one-half, whilst still further reduction could be made in the engine driving and greasing staff, as whilst steam engines require constant attention, the motors can be practically left to themselves, except for starting and stopping, as should anything go wrong with the motor it would be immediately detected in the central-station engine-room by the indicator corresponding to the particular motor at fault. It will be evident that we have dealt with the greatest source of economy by the concentration in one highly efficient plant for the generation of power for the whole of the main driving of the machinery of the works. It will be interesting, however, to consider the relation between the power at the main driving pulleys and that absorbed by the machinery in doing actual work. Referring again to the driving engines 1 to 8 (Table II.), it will be seen that the loss in driving the shafting, belts, pulleys, &c., range from 25 per cent. to 70 per cent., or an average for the six engines of 43 per cent. These experiments have been confirmed by some made by Mr. Westgarth, and referred to by him at a meeting of the Cleveland Institution of Engineers. Mr. Westgarth found that in an engine and boiler works he experimented on of the total power developed by the steam engine 59 per cent. was absorbed by the shafting and gearing, and in one of the workshops where two long lines of shafting were used for driving a comparatively small number of machines the power absorbed was 75·6 per cent. of the total. In another workshop where the shafting was well laid and rope gearing used for the main drives the percentage was 42. The average of the whole experiments is therefore about 50 per cent., consequently it appears that half the mean power would be saved if all the machines could be driven by independent motors instead of by line shafting. This in an existing engine works is, of course, impossible; but there are many instances where long drives may be divided with great advantage, whilst the independent driving of large tools would be another very desirable feature.

Table II.

An example of what may be termed ideal electric driving is that of the Bedson Wire Company of Middlesbrough, where the installation is the most perfect and complete that has as yet been attempted in this country. Every process connected with the manufacture of wire is carried out by means of electricity, the wire drawing, galvanising, spinning, and barb fencing machines, overhead and locomotive cranes, hydraulic pumps, induced draught fans, lathes, centrifugal pump, are all independently driven by electric motors. Owing to the entire absence of shafting and belting, the construction of the building is very light, and the convenience of the whole plant is most noticeable. The current is generated by a 600-H.P. dynamo driven direct by a three crank triple condensing engine with boiler of 160lb. pressure. A special tunnel, 350 yards in length, has been constructed for the conveyance of the conductors, and branches are taken from these to the 50 motors, which vary from 5 to 40 H.P. each. The lighting of the works is most complete, the greater part being carried out on the inverted arc principle, which is so perfect that there is an entire absence of shadows. The original plans for driving these works electrically were prepared by Mr. Selby Bigge, who appears to have given considerable attention to the question of electric driving. Before definitely deciding to put down such a novel plant, several experiments were necessary, for which purpose special machines were designed by Mr. Bedson, the Managing Director of the Bedson Wire Company. These experiments were made at Liége by Mr. H. Pieper, and were so successful that after an exhaustive series of tests the Directors of the Company decided to adopt the electrical installation in its entirety.

A novel feature in connection with the boilers at Messrs. Bedson's works is the application of Messrs. Ellis and Eaves's well-known system of induced draught. This is the second application of the system to land boilers, the first having been made at the Atlas Works, Sheffield, originally arranged with Lancashire boilers. These have gradually been replaced by ten single-ended boilers of the marine type, the advantages claimed being as follows:—

1. Considerable economy compared with the Lancashire boilers with Galloway tubes.

* I.H.P. with the dynamos not at work = 38·3.

† The small amount of water trapped here is due to the trap being placed very near to that of No. 3 engine.

Digitized by Google

2. Considerable reduction in space occupied.
3. Absence of smoke.
4. Greater elasticity of power.

In ordinary work, by maintaining a vacuum of 3in. at the fan, the combustion is at the rate of about 35lb. per square foot of grate surface, and one single-ended boiler can readily evaporate as much steam as three Lancashire boilers 27ft. by 7ft. with ordinary chimney draught. Where the demand for steam varies in a works the system is a great convenience, and this is especially the case for electric light installations. It is evident that with this system of draught, or with any other efficient system, the assumed consumption of 13 tons per day could be still further reduced.

From the comparison which I have made we may fairly conclude that the saving gained by the substitution of electrical driving in an old-established works would be considerable. Whether this saving would justify the outlay in all cases would have to be settled by those who have their capital invested in works suitable for its adoption. I may say, however, with reference to the firm of which I am a member, that for some time we have had the matter under consideration, and the various investigations and experiments made by Mr. D. B. Morison, and of which are those enumerated in this address, have so convinced us of the commercial possibilities of the system that we have now on order a small plant prior to further developments hereafter.

I have endeavoured to confine myself in my remarks to a plain statement of what has been accomplished by making use of electrical power to drive machinery, and have not gone into any of the possibilities the future may reveal. We have known the science of engineering to advance at times, as it were, by leaps and bounds, and, from the rapid strides that this comparatively new energy has made within the last few years, we may have reasonable expectation of still further development in this direction.

ON THE PROPAGATION OF ELECTRO-MAGNETIC WAVES IN ICE, AND ON THE DIELECTRIC POWER OF THIS SUBSTANCE.*

BY R. BLONDLOT.

In a previous communication† I enunciated the following theorem: The length of the waves which an electromagnetic oscillator is capable of emitting remains the same whatever the insulating medium in which the experiment is conducted; in other words, the wave-length depends only on the dimensions of the oscillator, in the same way as in acoustics the length of the waves emitted by a tube depends only on the length of the tube. The corroboratory experiments described in the above-mentioned communication related to castor oil and essence of turpentine. The law was perfectly true for these two substances, and everything tends to the belief that the same would be the case for other dielectrics. There was, however, some doubt with regard to one—namely, ice—owing to the exceptional properties attributed to it. M. Bouty's experiments, in fact, give ice a dielectric power of 78; that is, incomparably greater than that of all other substances.‡ Thinking that the law relating to wave propagation could not be applicable to a dielectric so different to all others, I decided to put the question to the test of experiment, to carry out which I took advantage of the intense and prolonged cold of the winter of 1892-93. M. M. Dufour assisted me in carrying out these experiments, which were rendered difficult and even painful by the low temperature, and I have to thank him for his extreme kindness on this occasion.

The method I employed was the following, identical, with the exception of a few modifications necessitated by the solid state of the dielectric, with that used by me in the case of castor-oil and essence of turpentine.

The electromagnetic waves were transmitted along two tinned copper wires 2·5mm. in diameter, stretched horizontally and parallel to one another at a distance of 0·8m. A resonator of gilded copper, the same as I used in the experiments with liquids, was installed at a fixed place between the wires. The portion of the wires beyond the resonator was contained in a wooden trough 4m. long. The trough being empty, it was sought to find the place where a movable metallic bridge had to be put across the wires beyond the resonator in order to make the spark disappear; the distance between the resonator and the bridge is a quarter of the wave-length natural to the resonator. The exact position of the bridge could be ascertained. This done, I surrounded the condenser portion of the resonator with a water-tight parchment bag filled with boiled distilled water. I then froze the water. The air layer of the condenser was thus replaced by a sheet of ice. Determining the wave-length once more, it was found to be much greater than in the first experiment. It had become about 141/100 of what it was at first. I then filled the trough with water, which I froze, then I again determined the position of the bridge, for which the resonator spark disappeared. To do this I broke and progressively cleared away the ice from the end of the trough furthest from the resonator, and I ascertained that the position was exactly the same as in the first experiment when air was everywhere the dielectric.

The experiment, repeated four times with the capacity of the condensers varied on each occasion, always gave the same result. The theorem with regard to the wave-length is therefore as true for ice as for other dielectrics. Consequently, as I showed in my previous communication, Maxwell's relation, according to which the specific inductive capacity is equal to the square of the index of refraction, is true for electromagnetic undulations through ice.

These somewhat unexpected results induced me to determine the dielectric constant of ice, making use of electromagnetic undulations. In fact, the experiment described above gave me the necessary data for this. If we denote by λ and λ' the wave lengths corresponding to a given resonator, when placed respectively in air and in a substance of specific inductive capacity K, we have $\lambda'/\lambda = \sqrt{K}$. As I stated above, I found $\lambda'/\lambda = 141/100$ from which we get in round numbers $K = 2$. The experiment repeated a dozen times always gave the same result. I estimate that the relative error does not exceed 1/20, since the layer of ice was almost free from air bubbles.

It only remains to explain how it was that MM. Bouty and A. Pérot arrived at quite other values for the dielectric power of ice. In the first place in M. Bouty's method, the charge and discharge of the condenser were far slower than in my experiments. Is it not probable, therefore, that the physical magnitudes measured by M. Bouty and by me were very different? In any case we at present know too little about the dielectric properties of bodies for us to be astonished at the divergence, however wide, between numbers obtained by two methods so dissimilar. Secondly, the results* given by M. A. Pérot, who worked by the method I have just described, are erroneous, as he has since admitted owing to an important omission in his calculations. Correcting this mistake, M. Pérot's experiments result like mine in a number near to 2 for the dielectric power of ice.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October* 5, 1894.

A New Alternating System.—The General Electric Company has just announced a new alternating system, under the name of the "Monocylic" system, for the simultaneous operation of incandescent lights and motors where the importance of the former predominates. The details have not been made public in full, but the generator is described to be similar to an ordinary alternating lighting generator, with the addition of a supplementary or "teaser" coil leading to a third ring on the armature shaft, from which a third or power wire is led. The motors are of the induction type, and are connected with a transformer, to which are led the two main wires and the third, or power, wire. This power wire is described as being small in size, as it only needs to carry a current sufficient to start the motors. The motor system seems really to consist in the employment of two-phased line currents, which are converted by a transformer into three-phased currents, the motor being started up as a three-phased motor, and, after arriving at synchronism, is worked as a synchronous induction motor. In this connection it is interesting to note that the phase-transforming principle described by Electrician Scott, of the Westinghouse Company, this spring, has several claimants for priority, and the same system seems to be used in the motor transformers of the "monocylic" system.

Death by Electricity.—At the meeting of the American Electro-Therapeutic Association last week, Messrs. Houston and Kennelly read a Paper on "Some Experiments on Death by the Alternating Current," in which they strongly contest the conclusions of D'Arsonval in regard to the possibility of reviving a criminal electrocuted according to the methods employed in New York State. While endorsing his suggestion that a person

Digitized by Google

shocked by electricity should be treated as if drowned, they remark that it is quite another matter with reference to a criminal subjected to a current of from five to eight amperes in strength. The conclusions arrived at from experiments in their laboratory are: First, that the passage of a sufficiently powerful alternating current through the body is followed by instantaneous, painless, and absolute death. Second, that consequently, where electrocution is properly carried out, there is no possibility of the resuscitation of the criminal. Third, that in cases of accidental contact, where the current passing is not excessive, it is quite possible that death may be apparent only, and that the method of artificial respiration suggested by D'Arsonval should then be followed. At the meeting of the same association, Prof. Dolbear, in a Paper on "The Physiological Effects of the Constant Current," stated that physiological functions of all sorts are electro-magnetic in their last analysis.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The 1894 Edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK contains 1,000 closely-printed pages, and several new and useful features have been added. The price of this edition of the Directory and Handbook is now 5s. post free; abroad 5s. 6d. *The 1895 edition is in active preparation.*

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell, with this title, will be ready in a few weeks. It will contain the latest information respecting the application of electric energy to mining purposes, in which the author has had much experience. The book is well printed, on good paper, and will contain nearly 250 illustrations, a large proportion of which have been specially made for the book. The price is 10s. 6d., post free 11s. (abroad 11s. 6d.). Orders can now be sent in.

"THE WORK OF HERTZ."—The lecture delivered by Dr. O. J. Lodge at the Royal Institution on June 1st is reprinted with corrections and additions, and many original illustrations, price 2s. 6d. net.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

TENDERS INVITED.—The Corporation of Sunderland invite tenders for wiring the Town Hall for the electric light, including the supply and fixing of cables, casings, switch and fuse boards, lamps, &c. Specifications, schedules, and general conditions may be obtained from the borough electrical engineer, and tenders must be delivered not later than 5 p.m. on Thursday, November 8th. Further particulars appear in our advertisement columns.

——— The Postmaster-General invites tenders for the supply of red fir telegraph poles, and for creosoting the same. Forms of tender, containing all particulars, can be had on application to Mr. Charles E. Stuart, Controller of Stores, Telegraph-street, London, E.C. Tenders have to be in by noon on Wednesday, the 31st inst.

——— Mr. John Annan, manager for the liquidator in J. W. Hobbs and Co. (Limited), invites tenders for the supply and erection of boiler house plant, engine house plant, switchboard, instruments, &c., for the electric light and power installation at the large block of hotel buildings now erecting on the Salisbury Estate, Victoria Embankment, and Strand, London, W.C. Plans and specification, &c., can be obtained of Mr. R. Hammond, consulting engineer, Ormonde House, Great Trinity-lane, E.C., on and after October 5th; and tenders must be sent in before Friday next, October 26th.

——— The Lighting Inspectors of Hapton (Lancs.) invite tenders for the electric lighting of the village and of so much of the township of Hapton as they may think necessary. Tenders must be in by the 27th inst.

TENDERS ACCEPTED.—At Tuesday's meeting of the London County Council the following report from the Fire Brigade Committee was submitted:—"We reported on July 24th that, as the contract with Messrs. H. Binko and Co. for the maintenance of the electric bells belonging to the brigade would expire early in August, we proposed to invite tenders for the maintenance for a further period, and that we had authorised the chief engineer to arrange for the work to be done by workmen directly employed by the Council until the new contract should be entered into, and the Council approved our action. We have now to report that the cost incurred in maintaining the bells, including the substitution of new batteries for defective ones, and the execution of repairs to the wires and apparatus, has been about £95. Six firms were invited to submit alternative tenders for the maintenance of the bells for one or three years, but only five responded, their prices being as follows:—

	One year.	Three years.
A. W. Jackson	£325	£285 0 0
Julius Sax and Co. (Limited)	325	303 6 8
Strode and Co.	330	330 0 0
J. D. F. Andrews and Co.	400	350 0 0
Nicholson and Tyler	1,050	1,000 0 0

The result of inquiries made by the solicitor with regard to the lowest tenderer appears satisfactory, and we recommend that the tender of Mr. A. W. Jackson to maintain for three years at the rate of £285 a year the electric bells belonging to the brigade be accepted."—This was agreed to, but with the proviso that the contract should be for one year only.

TENDERS ACCEPTED.—The tender of Messrs. Siemens Bros. and Co. (Limited) for the supply of conductors for the three-wire system, at £1,290, and that of Messrs. W. G. Bagnall and Co. for overflow mains and exhaust pipes for engines, at £75, have been accepted by the Stafford Town Council.

SALE BY AUCTION.—Messrs. Wheatley Kirk, Price, and Goulty announce in our advertisement columns the sale, at an early date, of the surplus plant and stock belonging to the London Electric Supply Corporation (Limited), at the Deptford Works.

BANKRUPTCY.—A receiving order has been granted in the estate of William Hopkin Akester, electrician, of 897, Fulham-road, London, S.W.

J. E. H. GORDON AND CO., LIMITED (IN LIQUIDATION).—We learn from the liquidator of this concern that there is no prospect of a dividend for the Ordinary creditors. The chief assets of the Company are electric light stations in Ireland, which have cost considerable amounts of money; but of which, in spite of strenuous efforts on the part of the liquidator, only one has been realised, and that for a small sum.

EXTENSION OF PLANT.—The proprietors of the City Terminus Hotel, E.C., have placed an order with Messrs. Robey and Co., of Lincoln, for a boiler and duplicate system of main steam piping, as designed by their electrical engineer, Mr. W. Durtnall, under whose control their electric light installation has been erected with complete success.

NEW FIRM.—Messrs. S. Haynes and Co. have started in business as art metal workers at 2, Longford-street, London, N.W. Mr. Haynes was, we understand, formerly with Messrs. Verity, of Regent-street, London, W. The business of the firm will be to supply the trade only with art metal work to requirements.

HOOKHAM METERS.—A new issue has been made by Messrs. Chamberlain and Hookham of the particulars and price list of Hookham meters. The list contains admirable illustrations of this well-known meter, and the letterpress includes a report by Mr. James Swinburne, and a reprint of an article on "Permanent Magnet Circuits," by Mr. Hookham, from the *Phil. Mag.* Instructions are given for setting up and starting the meter, and details of its special use in charging secondary batteries.

MESSRS. O. BEREND AND CO.—This firm send us copies of their new lists "A" and "S." The former deals with the "Daylight" incandescent lamps supplied by the firm, of which prices and particulars are given, with trade discounts. Illustrations of fancy lamps, which are made to order, and of high-voltage single-filament lamps are also included in the catalogue. Special attention is called to a single-filament 16-c.p. lamp made to work on a 250-volt circuit. The "S" list deals with switches, cut-outs, resistances, and other apparatus for electric light and power installations; this is very fully illustrated. These lists can be obtained by the trade on application to the offices of the Company, 61, Fore-street, E.C.

COX-WALKER'S SPECIALITIES.—A new catalogue is issued of these specialities, which include English-made telephones, electric dinner or alarm gongs, electric bells, fire alarm apparatus, lightning conductors, &c.

FIRE AT NORTH WOOLWICH.—A fire occurred at Messrs. W. T. Henley's works in Store-road, North Woolwich, on Wednesday night, with the result that the lead-covering shop was seriously damaged, but we are able to state that this damage will be fully repaired in about a week. No other part of the extensive works was injured, and business will be in no way interfered with.

PRESENTATION.—A smoking concert was given on Friday evening at Brighton by the employés of the old Brighton and Hove Electric Light Company, at which Mr. Willett, the engineer, was presented by his former colleagues with a handsomely-fitted portmanteau on

Digitized by Google

the occasion of his leaving the district to assume the post of electrician on Capt. McCalmont's new steam yacht.

Electro-Harmonic Society.—The next smoking concert will be held at the St. James's Hall Restaurant on Friday next, the 26th inst., at 8 p.m.

An Alleged Nuisance.—On Tuesday the Crystal Palace District Electric Supply Company (Limited) were summoned at the Greenwich Police Court at the instance of the Lewisham District Board of Works, for causing an effluvium to issue from their works at Springfield, Wells-road, Sydenham. Witnesses were called to prove that from time to time offensive vapours had been proceeding from a shaft at the Company's works; whilst, on the other hand, it was contended that the smell did not come from the Company's premises. A resident said that since the issue of the summons there had been an improvement; but Mr. Offor, the Managing Director, said there had been no alteration whatever in the fuel consumed, so that the smell complained could not have come from their works. The summons was eventually adjourned *sine die.*

Birmingham.—Col. W. M. Ducat, R.E., held a Local Government Board enquiry on Tuesday in the Council Chamber with regard to an application by the Corporation for sanction to borrow a sum of £55,741 for various purposes, including £1,000 for the electric lighting of the Market Hall. The Town Clerk said that this work had already been done, as the Corporation were anxious to have the light ready for the winter. No opposition was offered to the application, which will be reported upon in due course.

Bolton.—The Gas Lighting and Electricity Committee of the Town Council, on Friday, decided to issue a circular to the ratepayers, containing information as to the terms and conditions upon which the Corporation would be prepared to supply the electric current to premises within the borough. The electrical engineer reported that the works at the station in Spa-road were so far advanced that a preliminary trial of the electric lighting plant would very shortly be held.

Bow (London, E.).—The Vestry have decided to defer until after the next election the consideration of the electric light proposals of the Poplar District Board of Works.

Brechin.—At a special meeting of the Police Commission on Monday it was decided to support the application of the Scottish House-to-House Electricity Company to the Board of Trade for a Provisional Order. It was stated that the Company had agreed to at once take the necessary steps to obtain a Provisional Order at their own cost and responsibility; to lay down a thoroughly efficient plant for the electric lighting of the town; to allow the Local Authority, if desired, to acquire the undertaking at the expiry of ten years from the time of the introduction of the electric light into the burghs, and in the event of the Local Authority wishing to take over the undertaking at that period, then the Authority would, after 5 per cent. per annum had been deducted on a capital of £10,000, for depreciation, maintenance, &c., be entitled to receive 10 per cent. of the net profits of the undertaking until the undertakers earned 6 per cent. per annum and 20 per cent. upon all profits above 6 per cent. It was also agreed that the maximum charge should be 8d. per unit, and the Company further undertook to supply the electric current to the burgh at 25 per cent., light for light, below the present rate for gas in Brechin, viz., 4s. 7d. per 1,000 feet.

Bristol.—The negotiations for supplying the electric light to St. Mary Redcliff Church have come to a successful close, and the work of extension will be at once proceeded with.—On Monday a meeting of the Stoke's Croft and North-street Ratepayers' Association passed a resolution urging the Electrical Committee to extend the electric light in the direction of Stoke's Croft as far as Ashley Chapel as soon as possible.

Derby.—The Assembly Rooms at Derby have recently been lit by electricity. The building was originally designed by Adams towards the end of last century, including the interior decorations, and it was desired by the trustees that the very handsome candelabras should not be disturbed. These have been reconstructed by John Davis and Son, of Derby, into electroliers; the lamps resemble the candles they originally contained. Other electric lamps are fixed round the room into specially-designed brackets with floral decorations, thus reserving the general character of the decorations.

Douglas (Isle of Man).—The Town Commissioners at their meeting last week had before them a recommendation of the Health Committee that the lighting of the public lamps during the autumn and winter be handed over to the Douglas Gas Light Company on the usual terms. After some discussion this was agreed to; but an addition to the resolution was also carried that the Committee be instructed to make inquiries with regard to electric lighting, and submit a report thereon at the earliest opportunity.

Dublin.—The residents of Moore-street have been for a long time dissatisfied with the paving and lighting of the thoroughfare and at a meeting last week appointed a deputation to wait upon the Paving and Lighting Committee of the Corporation to urge that the roadway be made up, and that the electric light be introduced for the street lighting. The deputation accordingly waited upon the committee on Friday, with the result that the electric light is to be extended to Moore-street, the question of paving to be considered later on.

Elmore Copper.—We are asked to state that a number of steamships have been recently fitted with Elmore copper seamless steam pipes, including the following:—For W. Doxford and Sons, "Bencliffe" and "Caelens"; for Bertram Haswell and Co., "Queen Olga" and "Elderstein"; for Short Brothers, "Cordova" and "Tartar Prince"; for the Edwards Shipbuilding Company, "Canterbury"; for the Marquess of Londonderry, "Vane Tempest." It is stated that the Company's Leeds works have been kept busy with important orders for the Government, the railway companies and marine engineers.

Exhibition Award.—The Willans engine has gained a gold medal at the Lyons Exhibition.

Great Yarmouth.—The Town Council have decided to light the Town Hall by electricity, at an estimated cost of £300, and to extend the electric light to the Fish Wharf.

Hove.—At a meeting of the Hove Commissioners on Thursday last week, it was resolved to provide a silence box for the telephone in the basement of the Town Hall. It was stated that the electric light in the hall had been tested, and the result was held to be satisfactory; some minor alterations would be effected, and then the system adopted would be found to be a great success.

Kensington (London, W.).—The Select Electric Lighting Committee of the Vestry reported at the last meeting that they had had under consideration a letter from the Board of Trade asking them for any observations they might wish to make upon the amended description of the scheme by which the House-to-House Electric Light Company proposed to supply electric energy within the district of the Vestry; but that before doing so they had directed the Vestry Clerk to apply to the Company for information on various points. The matter was referred to the Electric Lighting Committee.

Leeds.—In reference to our Trade Note of last week relative to the newly-opened Medical School and College Hall of the Yorkshire College, we are requested to state that, whilst the electric lighting of the former building was carried out by Mr. Churton, the electric lighting of the Yorkshire College has been done entirely by Mr. Wilson Hartnell.

Liverpool.—At the meeting of the Markets Committee of the Liverpool Corporation on Tuesday it was urged by some of the members that the markets themselves were "the pink of perfection," and all that was necessary was the electric light. The Chairman agreed, saying he thought the improvement would soon have to be undertaken.

Llangollen.—A firm of electrical engineers having sought the permission of the Local Board to make an experiment in the lighting of the town by the electric current, the clerk was instructed at the last meeting to ascertain whether an order of the Board of Trade was necessary to the proposed experiment.

Londonderry.—Last week's meeting of the Lighting Committee of the Corporation was occupied for two hours in the consideration of the present condition of the electric lighting scheme. The meeting had before it an offer from Messrs. Siemens Brothers to re-lay one of the circuits, which they have found is not able to stand the amount of insulation resistance mentioned in the specification. Mr. Christie, the resident electrical engineer, said that Messrs. Siemens were going through the whole of the circuits and testing them carefully. In reference to the matter of the clause which was struck out from the specification after it had been approved by Dr. Hopkinson, Mr. Blake, the Corporation's electrical engineer, under whom the scheme was introduced, said that this clause was impracticable, and was inserted not by him, but by Dr. Hopkinson in the original draft specification. All the contractors had struck out this clause. It was ultimately proposed that a deputation should proceed to London to interview Messrs. Siemens Brothers and Dr. Hopkinson, but no decision was come to on the proposal. We understand the light is now working satisfactorily, and that no further failures have been reported.

Medical Battery Company (Limited).—We regret to learn that the business of Harness's Medical Battery Company has been re-registered with a capital of £15,000, under the title of the Medical Electrical Institute (Limited). The Directors may rely upon their proceedings being closely watched by the medical and electrical press, and it will be interesting to follow the steps taken by the Company to justify the two first words of its title.

Morecambe.—A complaint of an alleged nuisance created by the works of the Electric Light Company has been referred by the Local Board to the Medical Officer of Health.

Digitized by Google

Monmouth.—The Town Council held on Tuesday a special meeting for the purpose of inspecting various suggested sites for works in connection with the combined scheme for drainage and electric light.

Moss Side (Lancs.).—The School Board have had before them on one or two occasions the question of lighting the Princess-road School, and at the last meeting, after some discussion on the relative meritt and cost of the electric light and gas, the subject was referred to the Sites Committee for consideration and report.

Nottingham.—It has been decided by the Lighting Committee of the Town Council to light the Great Market-place by the electric light.

Portsmouth.—At the meeting of the Town Conncil on Thursday last week, the Electric Lighting Committee submitted a report dealing with their receipts and expenditure since the starting of the works. They recommended that application be made to the Local Government Board for permission to borrow £1,800, balance of the £60,000 which was authorised by the Council for the carrying out of the electric light installation. In moving the adoption of the report, Alderman Ellis said there was every probability of the Committee paying its way on the first year's working.

Royal Aquarium.—The Directors of the Royal Aquarium, Westminster, London, have got together a very interesting exhibition of pictorial posters by French and English artists, in which the fancies of the latter have been allowed full scope. It would appear that amongst the present-day fads is one for the collection of these "works of art," and collectors have lent many of their choicest specimens for this exhibition, for which a superbly-illustrated catalogue is in preparation, edited by Mr. Edward Beller. The exhibition opens at the end of next week.

Stafford.—The foundation stone of the electric light station was laid on Wednesday by the Mayor, Councillor G. Wormall.

St. Pancras (London, N.W.).—The Vestry deem it desirable to acquire the freehold of the King's-road central station site; and for this purpose, as well as to meet the contracts in connection with the destructor buildings and appliances, the central electric station buildings, electrical machinery and mains, a sum of £65,000 would be required. Application is to be made to the London County Council for a loan of this amount, repayable by equal instalments of principal and interest combined in 42 years.

The Telegraph Wire Export Trade.—As compared with the corresponding period of last year, an exceedingly brisk tone characterised the export trade of this country in telegraph wire and apparatus connected therewith last month, the exports amounting in value to £49,820, as against only £32,865 in September, 1893. The prevailing activity is more clearly shown by comparing the figures relating to the exports during the first nine months of the year. During the nine months ended September last the value of the exports of these materials has reached a total of no less than £1,304,894, as against only £766,224 in the corresponding period of 1893, and £800,440 in the first nine months of 1892.

Tonbridge.—At the meeting of the Local Board last week it was resolved to apply for a Provisional Order. The Holloway Electricity Supply Company (Limited) have already given notice of their intention to apply to the Board of Trade for similar powers over the Local Board's district.

Trentham (North Staffs.).—The Duke of Sutherland is having very extensive alterations made on his Trentham estate, at a cost of between £20,000 and £30,000. The work includes the electric lighting of the house, the dynamos being driven by water-power obtained from the river Trent.

Walsall.—At the meeting of the Town Council last week, the Gas Committee reported that the Local Government Board had refused to approve of the arrangement whereby it was proposed to pay £2,250 out of the loan for electric lighting purposes to the credit of the gas undertaking for the site of the central station at the Wolverhampton-street gas works, and the Committee had therefore decided to charge the electric light department £90 per annum as rent for the site of the station.

Warminster.—The Committee of the Local Board appointed to carry out the extension of the electric light reported at the meeting last week that they had instructed the surveyor to obtain tenders for the supply of a dynamo to run 7 2,000-c.p. arc lamps, six new lamps, a mile of cable and the necessary lead piping. This was approved by the Board, and the clerk was instructed to apply to the Local Government Board for permission to borrow the money.

Whitechapel (London, E.).—The District Board of Works on Monday decided to inform the Secretary to the City of London Electric Lighting Company that the site they offer to the Board for a power station will not be required, as in their present destructor premises excellent accommodation is afforded. By the utilisation of the waste heat in the destructor premises, the Whitechapel authorities hope to justify their provision of electric light, which they can supply at 5d. per unit, as against 8d. charged by the City Company.

Windsor.—At the last meeting of the Town Council, Alderman Dewe, Chairman of the Electric Lighting Committee, said that they had received a report from Mr. Shoolbred, who had been requested to report on the question of the electric light. He estimated on the capital account an expenditure of £18,500, and on the profit and loss account an expenditure of £1,680, and the probable receipts, at 7d. per unit, would come to £2,187, showing a loss on the first two years' working of only £443. He proposed that Mr. Shoolbred's report be printed and circulated, and that the question be considered at a future meeting of the Council, and that in the meantime application be made to the Board of Trade for a Provisional Order. After some discussion, this was agreed to.

Worcester.—The Electrical Exhibition, which will remain open until Saturday next, is proving a far greater attraction than was anticipated, the electrical cooking and the telephones connected to London theatres being among the most interesting features.——The Union Club is among the latest customers for the electric light, the premises being wired by the New British Electrical Installation Contractors (Limited).

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by Mr. J. C. Chapman, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

Note.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

14,922. FIELDER. Electrically operating semaphore signals.
15,276. KILIANI and OTHERS. Diaphragms for electrolytic purposes.
15,900. SIEMENS BROS. AND CO. (Siemens and Halske). Shunt arc lamps for alternating currents.
16,002. HOUSE and OTHERS. Refining metals by electrolysis.

RECENT FRENCH PATENTS.

229,858. PESCHARD. Certificate of addition to patent for an electro-hydraulic system.
238,558. HEILMANN. New method of elastic suspension of electric motors used for traction.
238,584. JOHNSSON. Electric gas lighter.
238,596. FRANK. Magneto-electric telephone.
238,609. BLASNY. Incandescent electric lamp.
238,612. CORBIN. Apparatus for the industrial treatment of aqueous solutions of various chemical compounds, particularly alkaline chlorides and alkaline earth, by the electric current.
238,626. THEODOLI. System of changeable luminous electric writing, and apparatus therefor.
238,633. CRANEY. Improvements in electrical apparatus.
238,698. HIGHAM ELECTRIC COMPANY. Improvements in electric arc lamps.
238,703. NÉTY. Continuous-current induction coil.
238,708. CRANEY. Improvements in electrolytic apparatus.
238,712. SPERRY. Improved method and apparatus for stopping the movement of mechanism actuated by electricity.
238,717. LAVILLE. New primary battery.
238,742. EPSTEIN. Process for keeping in working condition the positive plates of secondary batteries.
238,772. SOCIÉTÉ DES CUIVRES DE FRANCE. Process for the deposition of metals on revolving surfaces by electrolysis, called the "Paul David" process.
238,773. HAEFLIGER, VOGT AND CO. Electric fire alarm.

COMPANIES' MEETINGS AND REPORTS.

Brazilian Submarine Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended June 30, 1894, to be submitted to the forty-second ordinary general meeting to be held at Winchester House, E.C., on Wednesday next, October 24th, at noon :—

The revenue for the half-year ended June 30 amounted to £94,679. 16s. 4d., and the working expenses to £20,269. 9s. 11d. After providing £12,880 for debenture interest and sinking funds, and £1,736. 9s. 10d. for income tax, there remains a balance of £59,793. 16s. 7d., to which is added the sum of £2,207. 9s. 2d. brought forward from December 31st last, making a total of £62,001. 5s. 9d. A quarterly interim dividend, amounting to £19,500, has been paid, and £15,000 transferred to the reserve fund. The Directors now recommend the declaration of a final dividend of 3s. per share, making, with the interim dividends, a total dividend of 6 per cent. for the year, and also the payment of a bonus of 1s. per share, both free of income tax, which, together will amount to £26,000, leaving a balance of £1,501. 5s. 9d. to be carried forward. The dividend and bonus

Digitized by Google

will be payable on the 25th instant. On July 31st last the sum of £18,700 was transferred to pay off 187 bonds, the balance of the 1884 issue. The receipts for the half-year include the sum of £1,500 dividend to December 31, 1893, on the Company's shares in the African Direct Telegraph Company (Limited).

The various sections of the Company's line are in good working order.

Sir Henry D. Gooch, Bart., has resigned his seat at the Board, but it is not considered necessary to fill the seat at present. Sir John Pender, G.C.M.G., M.P., and the Hon. W. St. John Brodrick, M.P., retire at this meeting, and being eligible for re-election as Directors, offer themselves accordingly. The auditors, Messrs. Deloitte, Dever, Griffiths and Co., and Messrs. Gane, Jackson and Jefferys, also offer themselves for re-election.

Venezuela Telephone and Electrical Appliances Company (Limited).

The fourth annual report of the Directors, to be submitted to the general meeting of the Company, to be held at the Company's offices, 37, Lombard-street, E.C., on Tuesday next, at noon, is as follows:—

The accounts for the twelve months ended June 30th show a profit of £7,413. 5s. 11d., to which must be added the balance of £1,558. 9s. 7d. standing to profit and loss account. After providing the interest on the First and Second Mortgage Debentures, amounting to £4,393. 8s. 6d., the Directors have written off the sum of £1,711. 15s. 3d. from the discount and expenses on Debenture issues. This leaves a balance of £2,866. 11s. 9d., out of which the Directors recommend that a dividend on the Company's share capital be declared for the year ending June 30, 1894, at the rate of 4 per cent. per annum, which will absorb £2,800, and that the balance of £66. 11s. 9d. be carried forward. The Company's property having been fully maintained—as set forth by the General Manager's certificate at the end of the balance-sheet—the Board do not consider it necessary, at the present time, to make any allowance for depreciation of plant.

In the last annual report, the Directors informed the shareholders that the switchboard capacity in Caracas had been further increased by 200 numbers, and it with great satisfaction that they report that, owing to the steady growth of the business, the capacity is now being still further increased by another 200 numbers, thus providing accommodation in that city for 1,800 subscribers.

Mr. Edgar A. Wallis, the Company's general manager in Venezuela, being at present in England, will attend the general meeting, and make his report to the shareholders in person.

Sir Douglas Fox retires from office as a Director, and, being eligible, offers himself for re-election; as also do Messrs. Price, Waterhouse and Co., the auditors.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1894, pages 274-300, *&c., &c.*]

AKTIENGESELLSCHAFT FUR FERNSPRECHPATENTE.—Under this name a Company has been formed in Berlin, with a capital of £62,500, to acquire and dispose of patents relating to telephony.

ARIEL ARC LAMP SYNDICATE (LIMITED).—This Company has just entered into an agreement with Samuel Sealy-Allin and Charles S. G. Lloyd for the acquisition of the Provisional Specification dated July 4, 1894, No. 12,946, for a patent for "improvements in arc electric lamps," in consideration for the allotment as fully paid of 1,500 shares, of £10 each, to Samuel Sealy-Allin, and 400 shares to Charles S. G. Lloyd.

tists, chiropodists, Turkish and other bath proprietors, &c. The first Directors are Charles G. Elers and John Oliver (nominated by Ordinary shareholders), Arthur L. Poulter and Leopold J. Greenberg (nominated by Preference shareholders), and William B. Jones and Augustus Fleet (nominated by Second Mortgage Debenture holders). Registered office, 52, Oxford-street, London, W.

CHARLES JOYNER AND CO. (LIMITED).—This Company was registered on October 12th, with a capital of £35,000 in £10 shares, to acquire and take over as a going concern the business of manufacturers of and dealers in fittings connected with lighting by gas, oil, or electric light, carried on by Charles Joyner and Co. at Birmingham, and to carry on the business of manufacturers of and dealers in lamps, electroliers, ceiling roses, switches, shade and lamp holders, and other electrical fittings, &c.

MEDICAL ELECTRICAL INSTITUTE (LIMITED).—This Company is formed with a capital of £75,000, divided into 25,000 Seven per Cent. Preference Shares of £1 each and 20,000 Ordinary Shares of £2. 10s. each. Objects: To purchase, or otherwise acquire the lease, goodwill, rights, privileges, contracts, copyrights, trade-marks, patents, assets, and property of the Medical Battery Company (Limited); to carry into effect an agreement dated October 16th, between the Medical Battery Company (Limited) (in liquidation), and Herbert Banyard (for this Company); to provide for and carry out, under the control and superintendence of a duly-qualified medical man, the treatment of diseases by means of galvanic, electric, and magnetic appliances, batteries, baths, medical and other apparatus, and by massage, hydrotherapic inhalation, mechanical exercise (Dr. Zander's or any other system), chemical, dental, and other processes, and to carry on the business of manufacturers of and dealers in all kinds of galvanic, electric, magnetic mechanico, therapeutic, gymnastic, and other appliances, chemists and druggists, den-

STALYBRIDGE FOUNDRY COMPANY (LIMITED).—This Company was registered on October 10th with a capital of £15,000 in £10 shares, to acquire the business of ironfounders carried on at the Britannia Iron Foundry, Ashton-under-Lyne, Lancs., and to carry on the business of iron, steel, and brass founders, mechanical and electrical engineers, metal workers, &c.

AURORA ELECTRIC LIGHTING & DISTRIBUTION COMPANY (LTD.).—The annual return of this Company, made up to October 1st, has been filed; 5,935 shares have been taken up out of a capital of £25,000 in £1 shares, of which 5,000 have been issued as fully paid. Upon the remaining 935 shares the full amounts have been called and paid.

BABCOCK AND WILCOX (LIMITED).—The annual return of this Company, made up to October 2nd, was recently filed. The capital of £240,000 is divided into 10,000 £6 per Cent. Cumulative Preference and 14,000 Ordinary shares of £10 each. All these shares have been taken up, and 3,333 Preference and 4,666 Ordinary shares have been issued as fully paid. The full amount has been called on the remaining 6,667 Preference and 9,334 Ordinary shares, resulting in the total payment of £160,010.

BICKLE AND COMPANY (LIMITED).—The annual return of this concern, made up to October 3rd, was recently filed. 2,030 shares have been taken up out of a capital of £50,000, in £10 shares, and 1,000 of these were issued as fully paid. Resulting from a call of £10 per share on the remainder, £10,203 has been received, leaving £97 as yet in arrears.

BUENOS AYRES ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to July 3rd, has been filed. The Company has a nominal capital of £100,000, divided into 9,986 Ordinary shares of £10 each, and 70 Founders' shares of £2 each. All the latter have been taken up, but no calls have been made thereon.

CALIFORNIAN ELECTRIC POWER AND MINING DEVELOPMENT SYNDICATE (LIMITED).—The statutory return of this Company, made up to September 18th, and recently filed, shows that only the seven signatories' shares have been taken up out of a nominal capital of £30,000, in £1 shares. No calls have as yet been made upon these shares.

CITY NOTES.

BIRMINGHAM CENTRAL TRAMWAY COMPANY.—By an error a City Note in our last issue announced that the proposal made by the Directors of this Company to reduce the capital from £500,000 to £300,000 was passed unanimously. This was not the case; the Directors' resolution was rejected. Another extraordinary meeting to consider the proposal has been convened for Wednesday next.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended October 14th were £921, as against £851 in the corresponding period of 1893, being an increase of £70. The total receipts for the half-year amount to £12,931, as against £12,146 for the corresponding period of 1893, an increase of £785.

ISLE OF MAN ELECTRIC TRAMWAY COMPANY (LIMITED).—The Directors have issued a circular in which they state that, having carefully considered the profits for the past season, and having consulted with the auditors, they have, after providing a large sum for the reserve and renewal fund, and making provision for further dividends at the end of the year, decided to pay an interim dividend at the rate of 6 per cent. per annum on the Preference, and of 7½ per cent. on the Ordinary shares for the six months ending October 31st.

MILDE TELEPHONES AND ELECTRIC SUPPLY COMPANY (LIMITED).—The following letter deals with the attempt to obtain capital for this Company, referred to in our issue of Oct. 5th:—"Sir: Our attention has been called to a prospectus of the Mildé Telephones and Electric Supply Company (Limited). We beg to inform you that Mr. Charles Mildé has not consented to be a Director of that Company under any circumstances, as the articles of our firm will not permit it.—CH. MILDE, FILS AND CO., 26, Rue Laugier, Paris."

NEW GERMAN ELECTRICAL SYNDICATE.—It is reported that a Company is about to be formed in Berlin, under the auspices of the Diskonto-Gesellschaft and other leading financial houses of Berlin, for the purpose of financing electrical undertakings. The president is to be Herr Baurath Lent, of the Diskonto-Gesellschaft.

ST. JAMES AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—The electric current sold during the quarter ended September 29th last amounted to £6,935, as against £4,820 for the corresponding period of 1893.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended October 12th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited), were £3,093.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have decided to recommend the under-mentioned dividends for the six months ended June 30th last:—6s. per share on the First and Second Preference shares, and 6d. per share on the Ordinary shares.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—An extraordinary meeting of the shareholders of this Corporation is to be held at Eccleston-place, S.W., on Wednesday next, the 24th inst., at 11 a.m., to consider a proposition to increase the capital from £300,000 to £400,000.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 858.—Vol. XXXIII. FRIDAY, OCTOBER 26, 1894. PRICE FOURPENCE
Annual Subscription (U.K.), 19/6

NOTES.

At the meeting of the Westminster Electric Supply Corporation on Wednesday the Chairman was able to back up his request for £100,000 more capital by a very glowing picture of the lamp connection. At the beginning of this year some 132,000 8-c.p. lamps were connected to the mains of the Westminster Company; to-day that figure has been increased by 20 per cent., and applications are still coming at the same rate. It is also satisfactory to note that the desirability, not to say the necessity, of a substantial reserve fund is recognised, and that it is intended to commence betimes the tedious and, strange to say, frequently unpopular process of building up "an absolute reserve." Shareholders in electric supply companies, with the fate which has overtaken their tramway brethren in view, would do well not to put their trust in counsel's opinions, but to insist that adequate provision be made against the day of municipal purchase. Profits distributed up to the last penny may, no doubt, temporarily force up the market price of shares, and enable speculators to "unload" with advantage to their individual pockets; but moderate dividends and big reserves are the sheet anchor of electric light *investors.*

Small arc lamps, it would seem, are likely to become fashionable. We trust electric supply companies will not yield to the temptation of making their lamp connection "swell visibly" by reckoning, say a 500-c.p. arc as equivalent to 62 8-c.p. glow lamps. The watts demanded are the only reliable data to go upon.

What is *unfair* competition? We have heard so much about this strange bird of late that a satisfactory definition of it would be welcome. Such a relief, however, is not afforded us by the somewhat obscure letter signed "Consulting," which will be found in our correspondence columns this week. Letters over *noms de plume* rarely appear in our columns, as there are many objections to them; not the least of which is their tendency to mislead when *noms de plume* having no manner of connection with the writers' callings are assumed.

To define unfair competition as the poaching by manufacturers upon the preserves of contractors would at any rate be a clear enunciation of the grievance, whether the grievance itself were real or imaginary. But to lay it down as a law that makers of wires are not to be allowed to wire houses, whilst for "manufacturers of electrical sundries" to do so "is a step in the right direction," is ridiculous inconsistency. For our own part, we can see nothing "unfair" in cable-makers doing house-wiring if they choose. As to the degree of wisdom of the step, that will be determined by the rate of profit derived from the venture. As to whether it is "fair" or "unfair" that firms of manufacturers of electrical sundries should undertake wiring, we do not pretend to decide; but it is not at all clear that to do so "is a step in the right direction," for it is entering into competition with their own customers.

In the early days of the statutory electric supply business some companies made a mild attempt to "force a market" by doing a little house-wiring, but soon desisted, no doubt for excellent prudential reasons, such as the undesirability of arousing the hostility of the professional house-wirer and the difficulty of properly managing two totally different trades. Competition of this kind, had it been pushed, would, we doubt not, also have been dubbed "unfair," and would have given rise to a demonstration such as that recently directed against the Gas Light and Coke Company for trying to widen the market for gas by the sale and fixture of gas stoves at cost price. Capitalist competition of this kind is an unqualified good for the consumer, and as it neither diminishes the number of workmen in the particular trade or impairs their condition, it ought not come under the prohibition of those who consider that the ultimate end of a particular trade is to afford support to as many manual labourers as possible, regardless of all considerations.

The attempts of M. Broca to discover the law of the differential sensitiveness of the eye, while essentially a psychological problem, is of considerable practical interest to physicists in connection with the best length for a photometer bar. Inventors and advocates of different kinds of photometers are wont to claim wonderful accuracies for their instruments, expressed generally as errors of one-half or even one-fifth per cent. M. Broca shows that no such figure of merit has any meaning unless the illumination of the screens is given. The experiment with the Masson disc described in the abstract of his Paper, which we print in another column, is by no means an "extremely simple proceeding," as M. Broca states. His result, however, that for good photometric work an

Digitized by Google

illumination of about one carcel-metre, or say one candle-foot is best, is of practical importance. A very common photometric measurement by electrical engineers is the comparison of a 16-c.p. glow lamp, with an amyl-acetate or pentane standard. Here the distance between the lamp—that is, the length of the photometer bar—will be about five times the distance of the photometer from the standard. May the bar be as short as 2ft., or is any greater accuracy to be gained by making it as long as 10ft.? To obtain an illumination of one candle-foot it is clear that the length should be about five feet; a 50-inch bar would not be far wrong. With a 10-foot bar, the illumination would be 0·16 of a candle-foot; with so feeble an illumination minute differences are not distinguishable. M. Broca finds that there is a wide range over which the sensitiveness does not differ, but he is of opinion that it begins to diminish again under higher illuminations than about one carcel-metre. We have repeated his experiment, using, instead of Indian ink spots, which are far from black when brilliantly illuminated, perforations in a white card revolving in front of a box lined with black velvet. Dazzling did not appear to disturb the sensitiveness until 10 to 15 candle-feet was reached. Experiments in daylight or in a room with unshaded lights might give different results, but they would have no practical bearing on photometry. M. Broca's experiences as to the difference between the right and left eye, show that either both eyes together, or one eye only, should be used. The habit of standing so close to an ordinary Bunsen photometer that the reflections of the right and left-hand faces of the disc are seen with the right and left eye respectively is liable to give serious errors.

The "three-voltmeter" method of measuring power in an inductive circuit is well known, but the two-voltmeter method of generating power may, perhaps, be less familiar to our readers. We have before us a circular relating to a voltmeter of American origin, in which it is asserted in prominent capital letters, that these instruments "will actually save you from five to ten times the amount of electrical energy which is required for the operation of any other type of instruments." To construct a 100-horse-power plant on this system, it is only necessary to build a voltmeter which shall waste 10 to 20 horse-power, and then to buy one of these novel voltmeters; no dynamos or steam engines are wanted, a watt saved is a watt gained. It would be a dangerous experiment to proceed to buy an electrostatic voltmeter which wastes no power; the result might be, according to this mode of reckoning, the generation of an infinite amount of electrical energy.

We have received the following communication:—

The electrolunatic presents his compliments to the Editor of *The Electrician*, and desires to known why it is that in her Order in Council of August 23, 1894, concerning electrical units and standards, Her Most Gracious Majesty spells Ohm and Volt with capitals, and ampere without a capital.

Speaking for ourselves, we can hardly consider Her Most Gracious Majesty responsible for what may be only a clerical error, a *lapsus linguæ*, or a fault on the part of the P.D. (*diabolus imprimatoris*); but in view of the circumstance that Her Majesty is in Scotland, where thistles abound, we are disposed, on the whole, to consider it a case of *Carduus nutans*.

Cable Interruption and Repair:—

	Date of Interruption.	Date of Repair.
Macao-Hong Kong ...	September 25, 1894. ...	October 19, 1894.
Zanzibar-Mombasa ...	September 4, 1894. ...	—

Telephonic Communication in South America.—Telephonic communication has just been established between Montevideo and Buenos Ayres.

Personal.—Mr. Arthur Dearlove, of Messrs. Clark, Forde and Taylor, and a valued contributor to our columns, was married yesterday at St. Mary Abbot's, Kensington.

Institution of Electrical Engineers.—The annual dinner of this institution is fixed to take place at the Freemason's Tavern, Great Queen-street, on Wednesday, November 21st.

Swiss Customs Duties on Electric Material.—It has recently been decided by the Swiss Customs Department that all globes for arc lamps and glass bulbs for incandescent lamps imported into Switzerland are to be classified under Category 215, under which the duty is 6fr. per quintal.

A Tax on Bad Car Service.—In granting the right for the construction of an electric railway in a town near Berlin, the municipality requires that a fine of £100 be paid to the city if there is any interruption in the running of the cars for which there is not sufficiently good reason.

H.M.S. "Agamemnon."—*Engineering* announces that H.M.S. "Agamemnon" is to have auxiliary circuits carried to her turrets, so that an alternative means of firing her guns by electric current can be provided in the event of the main circuit becoming disabled. The vessel is also to be fitted with a new type of electrical semaphore.

City of London Electric Lighting Company.—The City Electric Lighting Company were summoned to Southwark Police-court on Wednesday for causing a nuisance to arise by the emission of smoke from their shaft. A representative of the London County Council having stated that alterations had been made to obviate the violation of the law, the summons was withdrawn.

Electric Tramways at Cape Town.—Some time ago two proposals were submitted by different parties to the Cape Town Municipal Council: one for the construction of a line of tramway along Caledon-street, and the other for a general system of tramway lines throughout the city, both systems to be operated by electricity. The Public Works' Committee, to which the proposals were referred, have just decided to recommend their adoption.

Cost of Electric Lighting.—Prof. Kennedy recently stated that before the Edison and Swan lamp patent expired, and when current was sold at 8d. per unit, an 8-c.p. glow lamp cost almost ¼d. per hour of actual lighting, whereas at the present price of glow lamps, and taking current at 6d. per Board of Trade unit, the 8-c.p. lamp costs ⅛d. per actual hour of lighting. Prof. Kennedy estimates the average life of glow lamps at 500 to 600 hours of actual lighting.

South-West London Polytechnic Institute.—Mr. Herbert Tomlinson, F.R.S., who has been for 24 years demonstrator and lecturer on natural philosophy at King's College, London, has been appointed Principal of the South-West London Polytechnic Institute, now in course of erection in Chelsea. The Institute, which will be of the same dimensions, and be conducted on somewhat the same lines as the Battersea Polytechnic, will, it is hoped, be finished by April next.

Competitive Boiler Trials.—The *Engineer* announces that Mr. James Howden, of forced draught reputation, has challenged all makers of water-tube boilers to a 30 hours' trial, conducted by neutral experts, of the respective merits of cylindrical and water-tube boilers. The points to be determined are:—(1) Weight; (2) space occupied; (3) evaporative power; (4) economy; and (5) waste of heat. The challenge is particularly directed at the Belleville boilers. The stakes are to be the expenses and cost of the boilers.

Insurance and Fire Risks.—Two special courses of lectures have been arranged at the Manchester Technical School in connection with the Insurance Association of Manchester. These comprise six lectures on "Fire Risks of Electric Lighting," by Mr. W. Haldane Gee, B.Sc., commencing Tuesday,

Digitized by Google

November 6th, and ending Tuesday, December 11th, and six lectures on "Chemistry in Relation to Fire Risks," by Mr. James Grant, F.I.C., commencing Tuesday, February 5, 1895, and ending Tuesday, March 12th.

Electric Traction in Belgrade.—The electric tramways in Belgrade, which have been constructed under a concession granted in August, 1891, have recently been acquired by a Belgian company, with a capital of £140,000. There are now seven different lines of tramway, on the overhead conductor system, running in the city and suburbs. The new company has, it is stated, contracted with the Compagnie Française de l'Eclairage Electrique de Belgrade for the supply of the necessary electric energy required at the rate of 15 centimes (about 1½d.) per kilometre when the number of car kilometres is below 1,000 per day, and 12 centimes (1⅕d.) when they exceed 1,000, which they are at present doing.

City and Guilds of London Institute.—The report of the Examinations Department, just issued, shows an increase in both the number of classes registered and the number of students in attendance. There were last season 853 classes registered by the Institute, viz.:—701 in technology and 152 in manual training. The total number of students in attendance was 25,718, viz.: 22,703 in technology and 3,015 in manual training. In the previous session the total number of registered classes was 734 and the attendance of students 24,374. At the examinations the total number of candidates examined was 11,631, being 1,377 in excess of the number examined last year. This is the largest increase since the foundation of the Institute.

The Hammersmith Vestry and the Electric Light.—The Electric Lighting Committee of the Hammersmith Vestry, having obtained a Provisional Order as Undertakers for the Supply of Electricity to Hammersmith, and also a complete Report on a lighting scheme, are desirous of gauging approximately the amount of support they are likely in the first instance to obtain, in order that the initial outlay on the works may be regulated accordingly, and utilised to the best advantage. To attain this laudable object the Committee have circularised probable consumers. Amongst other items of information afforded intending customers is that, from statistics compiled by Mr. W. H. Preece as to comparative cost of gas and electricity in nine chief towns of the United Kingdom, it has been ascertained that, light for light, gas rated at 3s. per thousand cubic feet is equivalent to electricity at 6d. per unit, the price at which the Vestry propose to sell.

The Lighting of Glasgow Cars.—A beginning will be made early next month with the lighting by electricity of the Glasgow Corporation tramcars. Each car is to be provided with a couple of accumulators, weighing about 40lb. apiece, placed at either end of the vehicle. There will be four lights on every car, each of 8 c.p., two being placed inside and two outside. The inside lamps are to hang from the ceiling, while the outside lights will be poised on poles above the heads of passengers. These outside lamps will be placed at the ends of the cars, and will serve the purpose of the bull's-eyes now used, as the glass facing outwards will be coloured to correspond with the name-board. The accumulators will only require to be charged once a day. The contract has been given to the Froggat Electric Lighting Company. Dynamos are being laid down at Paisley Road and at Coplawhill Stations. It is expected that by the end of the year all the cars will be fitted with the electric light.

Proposed Electric Railway to the Summit of Snowdon.—It is stated that there is now every prospect of the scheme for the construction of an electric railway to the summit of Snowdon being carried out in a very short time. There are two companies formed, and, as owner of the land, Mr. Assheton-Smith will take a leading part in the promotion of the project. The services of Mr. Duncan Fox, the engineer, have been secured, and his plans will probably be formed on the lines of those adopted for similar railways on the Continent. Unless unforeseen circumstances arise, it is, says the *Liverpool Post*, confidently anticipated that, with the advent of next season, this railway will be an accomplished fact, thus adding considerably to the importance of Llanberis as one of the starting points for Snowdon. In conjunction with this project the suggestion is made that the North Wales Narrow Gauge Railway Company should extend their line from Rhyddu to Beddgelert, so that people making the ascent of Snowdon on the Llanberis side might descend on the Beddgelert side, and so have direct communication with all places on the London and North-Western Railway. A Bill for the extension of this line has already been passed. The mountain has already been ruined by the follies of Sir E. Watkin, and a hideous railway cannot do much further harm.

Pacific Cable.—The Ottawa correspondent of *The Times*, under date October 21st, states that several weeks ago Mr. Sandford Fleming and Mr. W. H. Mercer, of the Colonial Office, left Ottawa for *Honolulu*, authorised by the Imperial Government to negotiate with the Hawaiian authorities for the purchase of Neckar Island, to be used as a landing place for the proposed Pacific cable. A San Francisco despatch says that their mission has been unsuccessful, the reciprocity treaty between the United States and Hawaii preventing the latter country from conceding any of its territory to Great Britain. Later advices state that the two Commissioners asked Hawaii for a lease of Neckar Island, and for a subsidy of £7,600 for 15 years. In return they would lay the cable and make the rate a shilling a word over the line, and a special Government and Press rate, on condition that Hawaii ceded the island to Great Britain in the event of a Hawaiian annexation to the United States. The Hawaiian Government, it is added, are willing to consider the proposal if the Commissioners accept a lower subsidy and forego the provision for the cession of Neckar Island to Great Britain in the event of annexation.

The Relative Merits of Arc-Light Machines.—A writer in *Cassier's Magazine* tells the following good story of how a dynamo salesman explained the reason for the complication in his dynamo armature winding:—

"One of the best known men in the electrical field told me recently of the manner in which he evaded a very serious question put to him in the infancy of his electrical experience, and when he did not know an armature from a bootjack. The competition this time was between the Brush arc dynamo and a Thomson-Houston. The representative of the former had advised the purchaser that the Brush machine had separate bobbins wound on the armature in such a manner that any one could be repaired in very short time by simply rewinding that particular bobbin without interfering with the other, whereas the Thomson-Houston armature was so complicated that if any wires should become defective which were several "layers" down, the whole exterior would necessarily have to be removed. When my friend who represented the Thomson-Houston Company was asked to explain this apparent defect in the construction of their armature he was nonplussed for a reply, as he had never seen both armatures together, and at that time did not know anything about the construction any way—in fact, was a greenhorn as far as detail was concerned. After hesitating a few minutes, he replied that an explanation was very easy. The Brush dynamo was expected to, and actually did, burn out very frequently, hence provision for taking care of such an abominable occurrence, while the Thomson-Houston never burnt out—in fact, owing to the design that was impossible, and, therefore, the Company had no need to arrange to take care of rewinding."

Over-Compounding Dynamos in Parallel.—In a recent issue of the *Electrical World* of New York Prof. E. P. Roberts calls attention to a case of over-compounding, where, instead of securing the regulation of voltage desired, the reverse is the case. If two or more dynamos are connected in parallel and each compounded as usual for a certain line loss, the regulation of voltage aimed at will only be attained when all of the machines are kept in circuit. For if the load becomes light and one or more be disconnected, then those still left in circuit will over-compound, not for the current on the line, but for the current in their armatures. If only one machine is left, for instance, and it is heavily loaded, the increase in voltage may be a maximum when it might happen that the load on the line is a minimum, thus subjecting lamps to an abnormal voltage. Two methods are pointed out by means of which this fault may be obviated; one consists in having a multiplicity of exterior circuits independent of each other, which seems to be impracticable; the other necessitates the use of rheostats in the shunt circuit, or, in other words, a double waste of energy, in both the series coil and the rheostat. Neither of these methods is satisfactory, and it would seem that in the case considered the best solution would consist in the employment of plain shunt dynamos if there is a large and gradual variation in load.

Novel Application of Accumulators for Traction Purposes.—There is, says the *Electrical World* of New York, a double

Digitized by Google

track section of about a half mile of the Chicago North Side Passenger Railroad Company in the heart of the city over which the Company finds it necessary to run its cars, but on which it cannot get trolley privileges. For this purpose the Electric Storage Battery Company, Philadelphia, Pa., will furnish the road with trucks, each carrying 240 battery cells of the "chloride" type; but nothing else except a motorman and a small motor sufficient to run the truck for switching purposes, but not sufficient to run a car. When a car arrives at the end of the trolley-wire a truck will run in behind it, couple on to it, and connect its battery with the motor on the car, and the motorman on the car will operate it the same as though he had the trolley, the voltage of the current being the same. When the car reaches the end of this section of the line, the truck will be uncoupled, mechanically and electrically, switched around by its own motor, and connected to another car going back to the other end. It is expected that on this part of the line there will be 25 cars in use in the busiest part of the day, and the battery company is to furnish 40 trucks equipped with batteries, which will be charged in place on the trucks, the number relieved from duty in the slack times, with the reserve of 15, being estimated as sufficient to allow this to be done.

Obituary.—We regret to have to record the death of Mr. Edwin Clark, M.I.C.E., which occurred at Marlow on the 22nd inst. Mr. Clark was born at Marlow in 1814. At some personal labour and perseverance he went to Cambridge University, where his fondness for mathematics found vent. He became one of Robert Stephenson's chief assistants at the construction of the Conway and Britannia tubular bridges. It was while thus employed that he became, through his friend Stephenson, connected with the original Electric Telegraph Company (incorporated 1846), and which subsequently became by his exertions the "Electric and International Telegraph Company," he being the engineer for the submarine cables which were laid from Orfordness to Scheveningen, and which were the longest and at that time the lightest submarine cables in existence. It is well known to all of what must now be called an almost past generation how the work and extension of the electric telegraph prospered in his hands. He made the principal agreements with all the railway companies then in existence for providing the telegraph for their lines, which was done at a rental to the railway companies, but reserving a way leave and other advantages to the Electric Telegraph Company, which he was then serving. The Post Office authorities of the present day may not, perhaps, think well of his memory in this respect, but the railway companies will think otherwise. History will record that Edwin Clark was one of the great electric telegraph pioneers of his day, and his old assistants still take pleasure in remembering that they were associated with him.

The Heating Power of a Glow Lamp.—While an ordinary incandescent is the least likely of all illuminants to ignite inflammable materials, there are special conditions under which its heat will start combustion in highly combustible substances. The *Gas World* observes that Mascart found that a glow lamp of 32 candles set fire to cotton wool saturated with indiarubber, and packed round it, in two minutes; to black silk in six minutes; and to a double layer of cotton cloth in two minutes. The same materials not saturated with indiarubber did not take fire. Capt. Exler, of the Austrian army, now finds that a 16-candle lamp, sunk in paraffin, reaches a maximum temperature of 94°C.; one of 25 candles, 101°C. A layer of gunpowder, ecrasite, or pulverulent pyroxiline is not set on fire by this: the ecrasite melted and the gunpowder lost all its sulphur. If the substance be spread on a material, *e g*, wood, which is opaque to heat-rays, the action is more marked, when the lamp is brought very near to it: the ecrasite melts, the pyroxiline darkens, the gunpowder loses its sulphur, and the nitre melts and the wood chars. Two lamps in a cavity of wood get up a temperature of 215°C., a charring temperature; but the explosives did not go off, though they decomposed. When the cavity was filled with water it boiled in 15 minutes. The spark produced on turning off the flame only kindles these explosives when they have become very dry; but the spark produced on switching off a feeble resistance between two lamp wires can do so readily. If the lamp breaks, pyroxiline or gunpowder does not ignite, but an explosive gaseous mixture will do so.

The Past and Present of a Condenser.—Messrs. Bedell and Kinsley have recently made a study of the residual charges of condensers and their dependence upon temperature. The action of a condenser, they find, is dependent, in a marked degree, upon its previous history; so much so, in fact, that its previous charges may be of more importance in determining its action under certain circumstances than charges received later. In that case the previous absorption, after neutralising the absorption due to the final charge, may give rise to residual discharges which increase with time up to their previous initial value. Absorption gives rise to the phenomena of residual charges, and causes the condenser to depart from the exponential law in discharging through its own dielectric. The increase in apparent resistance in the condenser during discharge is associated with this effect of absorption. Previous charges modify these results, increasing or decreasing them according to whether the previous charges were in the same or opposite sense. The resistance of pure oils is constant at any one temperature, but falls off rapidly with the temperature. There are, accordingly, no absoption or residual effects in pure oils. In solid dielectrics the effects of absorption are diminished as the temperature is increased, as shown by the residual discharges and by the changes in the insulation resistance. Many of the results described are already known, but they have not before been presented together so as to show the relation between them. The fact that the previous condition of the condenser has such an influence upon its action, causes considerable embarrassment in an investigation of this sort, inasmuch as a condenser used once under certain conditions may be practically useless in the same investigation for further experiments. One of the condensers experimented upon retained its past charges after being short-circuited for a month, and it was necessary to employ another condenser which was neutral, for further experiments.

Thermo-electric Force of Electrolytes.—The *Annales de Chimie et de Physique* for September contains a Paper, by M. Henri Bagard, on the thermoelectric force between two electrolytes, and on the Thomson effect in the case of electrolytes. The Paper, says *Nature*, contains a very complete history of the work which has been done on this subject. The author uses a number of thermoelectric junctions joined in series, and measures the electromotive force developed by a given difference in temperature between the hot and cold surfaces of separation between the electrolytes by means of a capillary electrometer. This electrometer was capable of indicating an electromotive force of $\frac{1}{100000}$th of a volt. In order to check the diffusion which takes place at the common surface of the electrolytes, the author uses a porous membrane. By using membranes composed of such different substances as goldbeater's skin and vegetable parchment, it was proved that the membrane had no effect on the electromotive force, except to cause it to diminish slightly with time. Thus the results obtained with a membrane are probably identical with what would be obtained could observations be made without a membrane, and without diffusion and convection currents being set up through the surface of separation. Observations were taken both while the temperature of one junction was rising and again when cooling. The points obtained during the second of these operations often fell below the curve given by the previous set. This effect, which never amounted to a difference of $\frac{1}{10000}$th volt, the author considers to have been entirely due to diffusion. Thermoelectric couples, consisting of solutions of two different salts, and of solutions of the same salt but of different concentration, were examined, and the results obtained are shown by means of curves. In order to examine the Peltier and Thomson effects in the case of electrolytes, small bolometers were employed to measure the change in temperature. The important fact that the Peltier effect is of opposite sign on opposite sides of the neutral point was amply verified, and it appears that the change of sign takes place at the neutral point. In all cases the thermoelectric phenomena, the Peltier effect and the Thomson effect gave results in the case of electrolytes similar to those obtained with metals.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Continued from page 595.*)

Superheating also has been adopted with a view to prevent initial condensation. With superheated steam, the fluctuations of cylinder temperature take place to the same extent, or nearly so, as with saturated steam; but the effect of introducing properly superheated steam into the cooled cylinder is to cause the steam to be reduced to a state of saturation, but without condensation. Superheating has just the same limits of value, in respect to engine speed, as the steam jacket has; and, while experiment shows that an economy of 20 per cent. or more can be effected in the case of very slow speed engines, it is improbable that there would be any economy with the high speeds commonly adopted in some types of electric light engines. Superheating has this advantage over the steam jacket that, when the degree of superheat is properly adjusted, there will be no loss of heat during the exhaust stroke; whereas, with the jacket, heat is to some extent imparted wastefully to the exhaust steam during the entire exhaust stroke.

Another important mode of reducing the evils consequent upon condensation and re-evaporation of water consists in properly draining the cylinder during exhaust. This does not directly prevent the formation of water; but, by clearing away the water immediately the release occurs, it tends to prevent the wasteful fall of cylinder temperature and the back pressure consequent upon re-evaporation in the cylinder. Mr. Bryan Donkin's researches on condensation, however, would seem to show that the steam is condensed as a fine film over the cylinder walls, and that it is improbable that any very large proportion of this water could be removed by drainage. Liquefaction by adiabatic or approximately adiabatic expansion probably leads to the formation of wetness of a different type, and of a kind which is more readily drained on release. This would appear to be supported by the fact that in some engines where the expansion is practically adiabatic, re-evaporation is found to be reduced by thorough cylinder drainage.

Influence of the Ratio of Expansion.—Thermodynamical considerations show that in order to obtain a high value for the limiting efficiency of a steam engine there must be as great as possible a difference between the temperature of admission and the temperature of rejection of the steam. This is a requirement which directly conflicts with the attempts to prevent initial condensation, in so far at any rate as only one cylinder is considered. Neglecting for the time being the losses due to condensation, we will consider the relation of the ratio of expansion to the economy of steam. Subsequently, we will see how the relation is modified by condensation, and how the conflicting effects may be reconciled.

A comparison between curves *e* and *f* in Fig. 9, will show that with steam at any given pressure a higher limiting efficiency can be obtained by exhausting it at 60°F. than at 212°F. Equation (67) proves the same, for any general case. Curve *a* in Fig. 9 shows that to obtain this fall in temperature the steam must fall in pressure, over a range which becomes greater as the initial pressure is lessened. But it is insufficient to show that the mere theoretical limit of efficiency requires this. It must be shown that, neglecting initial condensation, the actual efficiency is improved by a higher range of expansion. Let us assume adiabatic expansion in the cylinder, in order that only the intrinsic energy of the cylinder steam may be taken into account. Let it also be assumed that one pound mass of saturated steam, at an absolute pressure of P_a lb. per square foot, and having a density of Δ lb. per cubic foot, is admitted into a cylinder, and expanded to R times its initial volume. The work done during admission will be obtained by dividing P_a by Δ; and the work done during expansion may be determined by integrating the adiabatic expansion curve between the limits of initial and final volume. Thus the total work, W, done by the pound of steam will be:

$$W = \frac{P_a}{\Delta} + \int_{V_1 = \frac{1}{\Delta}}^{V_2 = \frac{R}{\Delta}} P \, . \, dV ;$$

and since, approximately,

$$P^{\frac{9}{10}} = \frac{330 \cdot 36}{V}$$

we obtain the following, by integration,

$$W = \frac{P_a}{\Delta} + k \Delta^{\frac{1}{9}} \left(1 - R^{-\frac{1}{9}} \right), \quad . \quad . \quad . \quad . \quad (86)$$

where *k* is a constant for the fixed quantities. This expression directly shows that, the other quantities remaining constant, the indicated work obtained from a pound of steam increases as the ratio of expansion in the cylinder is increased. Consequently, to obtain a low consumption of steam per I.H.P. per hour, the ratio of expansion must be high.

We have already observed in a previous article that it is useless to expand the steam down to a lower pressure than that of the exhaust. As a matter of practice, it is found that it is economical to release the steam at a slightly higher pressure than the exhaust, as the sudden drop of pressure serves to sweep a considerable quantity of the steam out of the cylinder, and avoids the work of clearing out this steam being imposed on the piston. Moreover, the sudden drop of pressure on release assists cylinder drainage, as well as indirectly reducing the percentage loss of power due to engine friction. When the expansion has been carried down to the lower limit of pressure, the ratio of expansion can only be increased by the use of still higher initial steam pressures. It is instructive to notice, by comparing equations (86) and (72), that even if the ratio of expansion is unaltered, while the pressure of steam is increased, the work done per pound of steam will increase. So that, if the ratio of expansion is increased by the practice of using higher steam pressures, there will be a double reason for an improvement being effected in the economy.

More about Condensation.—It may seem a pity that all the nice conclusions we have been able to draw from equation (86) must be upset directly we turn our attention again to the disastrous phenomenon of initial condensation. Were it not for this wasteful effect, it would be possible to go on improving the economy of the steam engine, asymptotically approaching perfection, merely by the use of higher pressure steam, less clearance and an earlier cut-off. As a matter of practice, this is quite impossible; and with every steam engine it is found that there is a limit to the range of expansion, beyond which the economy ceases to be improved, but rather is injured. The direct reason for this is that when the range of temperature of the steam in a single cylinder exceeds a certain number of degrees, depending on the speed of the engine, all known methods of coping with the initial condensation utterly fail, and the engine gives itself over to the wholesale production of water. Before that crisis is reached, the limiting ratio of economical expansion for that particular cylinder has been arrived at.

Compound Expansion.—The only remedy, if it is desired to have still higher pressures of steam and to expand it a further amount, is to use two or more cylinders, expanding the steam in stages. This is the principle of compound and multiple expansion. If steam at 150lb. pressure cannot be economically expanded down to 5lb. pressure in a single cylinder, we expand it down to only, say, 25lb. pressure in the first cylinder, and then pass this expanded steam into a second cylinder, where it is expanded again, down to 5lb. Or, if this gives too high a range of expansion in either cylinder, we may introduce an intermediate cylinder, adopting triple expansion; expanding from 150lb. to, say, 60lb. in the high-pressure cylinder, then down to, say, 20lb. in the intermediate cylinder, and finally down to 5lb. in the low-pressure cylinder. Higher pressures of steam may make it necessary to have quadruple expansion. The hotter steam never touches the cold walls of the later

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

cylinders, and the colder expanded steam never touches the hot walls of the earlier cylinders. Consequently, although the finally exhausted steam may be two or three hundred degrees cooler than the initial steam, no more than a permissible amount of condensation takes place.*

It must be pointed out that the object of using compound or multiple expansion is not to obviate liquefaction of steam during expansive working, as is erroneously stated in some text-books. In the first place, as we have shown, the working liquefaction of steam is not a direct loss at all; and, in the second place, no amount of subdivision of the expansion can affect it.

Compound Engines.—Compound engines, or engines in which two stages of expansion are performed, may be classed under "Woolf" and *receiver* engines, or under *tandem* and *side-by-side* engines. The former division relates to the mode of distributing the steam; the latter, to the mode of fixing the cylinders. In the Woolf engine, in which we have the distribution first adopted in compound engines, the expanded steam from the high-pressure cylinder is passed directly to the low-pressure cylinder, expanding to fill the latter during the exhaust stroke of the former. In the receiver engine the expanded high-pressure steam is exhausted from the high-pressure cylinder into an intermediate closed vessel, or receiver, in which it remains until it is required to be passed into the low-pressure cylinder. Tandem compound engines are those in which the high and low-pressure pistons are fixed to the same piston rod, the high-pressure cylinder being bolted on to the end of the low-pressure cylinder. In the side-by-side pattern the two cylinders are separate, and the two pistons, each with its separate piston and connecting rods, actuate two cranks usually on the same crank shaft. (When the side-by-side arrangement is adopted for two cylinders not compounded, the term *twin cylinders* is sometimes used.) Most commonly, the two cylinders are placed on either side of the fly-wheel in horizontal engines, and on the same side in vertical engines.

A little consideration will enable the reader to see that with the Woolf system of steam distribution the high and low pressure pistons must commence and end their strokes simultaneously; and, if the upper half of the high pressure cylinder (assuming the cylinders to be vertical) gives steam to the upper half of the low pressure cylinder, the one piston must be making an up stroke whenever the other is on the down stroke, while if the steam passes from the upper half of the one to the lower half of the other the pistons must move in similar directions. In the former case the cranks must be at 180°. As a matter of practice, owing to the fact that clearance space and compression render it possible to throw the pistons slightly out of synchronism without serious consequences, it is sometimes the custom to have an angle of slightly less than 180° between the cranks; this arrangement enabling the dead-centres which would otherwise occur to be avoided. With the receiver engine it is possible to have the cranks set at right angles, and even to place the cranks on independent shafts running at different speeds. Cranks at 90° are most commonly adopted for horizontal engines, owing to the greater equalisation of the combined crank effort when this arrangement is adopted; but the balancing of reciprocating parts which can be obtained in vertical engines when the cranks are at 180° gives rise to this plan being used in most side-by-side vertical compound engines, except where the equalisation of crank effort is a matter of greater importance than the absence of balancing. Tandem vertical compound engines are largely used in electric power stations, and are most commonly grouped in twos or threes on the same crank shaft; the advantage of this method being that the reciprocating parts of one engine can be balanced against those of the second, or the reciprocating parts of three be balanced against one another, and an equable crank effort at the same time be obtained. Consequently, both the Woolf and receiver systems of compound distribution of steam are to be met with in electric power steam engines. We will now study these two systems a little more closely.

The Woolf Engine.—In Fig 27. a pair of indicator diagrams from the two cylinders of a Woolf engine are shown, on a system of scale drawing which will be explained in another article. The upper diagram is that taken from the high pressure cylinder; the lower is that from the low-pressure cylinder. Steam is admitted into the first cylinder at *a*, and continues to be admitted until the cut-off point *c*. At *b* the high pressure piston commences its stroke; and the little kink in the diagram at this point is due to a false jump in the indicator pencil, caused by the momentum of its rapid ascent from *a* to *b*. High-pressure expansion occurs from *c* to *d*, and at this latter point release takes place, and the steam at once rushes from the first cylinder to fill the exhaust passages between the two cylinders, as well as to fill the portion of the second cylinder which is open to it. Hence the sudden drop in pressure to *e*. The point *d* on the high-pressure diagram here corresponds to the point of admission *f* on the low-pressure diagram; this arrangement giving, as will be seen, a small pre-admission into the second cylinder. Compression in the high-pressure cylinder

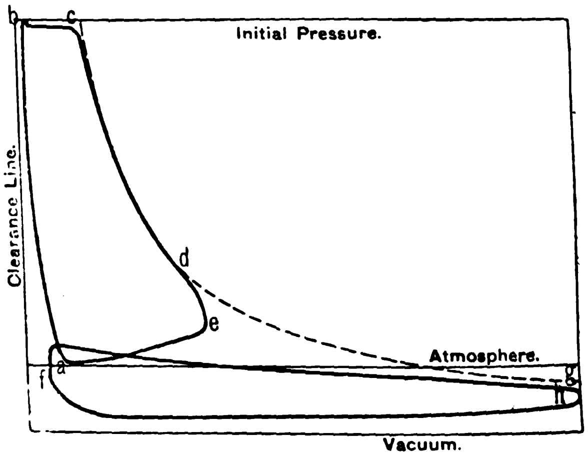

Fig. 27.

is not necessary, as it is possible to effect all the necessary economy by compression in the second cylinder, while the cushioning requisite for arresting the momentum of the piston may be produced in other ways, such as by very early admission or by means of an air cushion. Since there is a clear communication between the two cylinders all the time from *d*, past *e*, to *a*, it is evident that the expansion of the steam by its admission into the second cylinder must be accompanied by a fall of pressure, which will represent both a fall in the effective pressure on the low-pressure piston and a fall in the back pressure on the high-pressure piston. Thus, while the back pressure in the high-pressure cylinder falls from *e* to *a*, the working pressure in the low-pressure cylinder falls from the commencement of the stroke to about *g*, the point where the communication between the cylinders closes. Shortly after *g* is passed the low-pressure steam is released, and the final exhaust into the air or condenser—in the actual case under consideration, it being the condenser—takes place along the line *g h i*. At the last-named point the compression of steam into the low-pressure clearance space takes place, and continues until the point of admission *f* is again reached.

Remembering that in the diagram (Fig. 27) the two pistons are assumed to be moving in opposite directions, it will be easy to determine the values of the steam pressures in the two cylinders at any one moment. If, then, we compare the pressure in the high-pressure cylinder at any time during the exhaust, *e a*, with the pressure in the low-pressure cylinder at the same instant, we shall always find that the former has a

* It may here be observed that it is sometimes claimed that compound and multiple expansions lead to an immense saving of steam from condensation; while, on the other hand, it is often asserted that the amount of cylinder condensation in compound and multiple expansion engines is as great as in single cylinder engines, or even greater. Both statements are right, and both are wrong. For, if the range of temperature in each cylinder of a compound engine is as great as that in any given single cylinder engine, it is certain that the condensation will be as great or even greater in the former type than in the latter. On the other hand, if a compound or multiple expansion engine is worked with a *total* ratio of expansion equal to that in any given single cylinder engine, it should be found that more condensation will occur in the single cylinder than where the same expansion is sub-divided among two or more cylinders.

Digitized by Google

higher value than the latter. As there is a clear communication between the two cylinders, this drop of pressure can only arise from wiredrawing of steam in the passages and on account of unresisted expansion into the more roomy second cylinder. It is from this cause that it happens that a lower final pressure is reached with compound expansion than with the same amount of cylinder expansion in a single cylinder, a fact which is illustrated by continuing the high-pressure expansion line in Fig. 27 in a dotted curve; when it is seen that the final pressure lies below this curve. The dotted curve must be drawn to follow the same law of expansion as that in the two cylinders.

The Receiver Engine.—A pair of indicator diagrams taken from the two cylinders of a receiver engine, and corresponding in every respect with the Woolf engine diagram in Fig. 27, is shown in Fig. 28. The chief points to be noticed relate to the periods when the high-pressure cylinder is exhausting, and when the low-pressure cylinder is making a working stroke. The relation between the two periods depends on the crank angle, *i.e.*, on the phase difference between the two strokes. In the present instance the cranks are at right angles, so that the end of the stroke of the high-pressure piston corresponds to the middle of the low-pressure stroke—a point somewhere in the low-pressure expansion period, just after the cut-off. At the commencement of the exhaust stroke in the high-pressure cylinder there is no through communication with the low-pressure cylinder; the exhaust, therefore, takes place into the receiver, the pressure in which rises, as shown by the portion of the curve *a b*. At *b*, however, the low-pressure cylinder commences to take steam, and a through communication is established, resulting in a fall in pressure in both the receiver and high-pressure cylinder, as shown by the portion of the curve *b c*. At the point *d* the low-pressure cut-off takes place, and from this point onwards the low-pressure steam expands in the second cylinder alone. The character of the diagrams is not only affected by the relative positions of the cranks; it is also influenced by the relation between the cut-offs in the two cylinders, and by the capacity of the receiver. The relation between the two points of cut-off cannot be varied arbitrarily, in any particular engine, without running the risk of injuriously upsetting the balance of the loads on the two pistons, by a reaction upon the receiver pressure. It is the usual practice to divide the normal load equally between the two pistons, and to design the valve gear so that as closely as possible there shall be an equal division of labour whatever the load may be. In some engines, however, it frequently happens that at reduced loads there is far from equality between the loads on the two pistons.

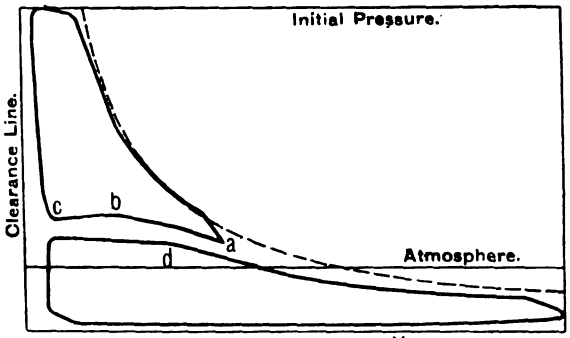

Fig. 28.

(To be continued.)

Cheap Telephones.—According to *Engineering*, in the town of Korsör, in Denmark, the inhabitants, who were dissatisfied with the rent they had to pay to the existing telephone company, which belonged to a neighbouring town, have formed a new company, with an annual rent for subscribers of 35kr., or £1. 19s., for the first year, and 30kr. (£1. 1s. 6d.) for subsequent years.

SOME NOTES ON THE GOVERNING OF STEAM ENGINES, PARTICULARLY WHEN COUPLED TO DYNAMOS.—II.*

BY G. L. ADDENBROOKE.

The article reproduced from the *Engineer*, and Mr. Mark Robinson's letter in last week's journal on practically the same subject as my first communication, are interesting as presenting the question purely from the "steam engineer's" point of view.

The *Engineer* complains that "the much-desired governor is not forthcoming because the electric light engineers have not explained fully what they want, and—which is perhaps more to the purpose—why they want it." Curiously enough that was one object I had in mind when beginning these notes, and the first article provided a qualitative reply, which it may be worth recapitulating here.

It was shown in the first place—what is not kept always in view as much as it ought to be—that the object of a central station is to supply electric current at a perfectly even pressure under all circumstances at the consumers' lamps.

Next, it was pointed out that in order to effect this the pressure on the omnibus bars at the station required to be varied according to the load, increasing as the load become heavier, and, lastly, it was noted that to produce a given voltage dynamos required to run faster at heavy loads, or to have their excitation increased. Further, it was shown that these conditions might be met in two ways, either the engines might be arranged to run always at constant speed, whatever the load, the variation in pressure being produced electrically by the use of variable resistances in the main circuits, and the exciting circuits of the dynamos, or, secondly, the requisite increase of pressure might be obtained by running the engines faster at heavy loads than at light—that is to say, by over-governing.

This is the nature of the problem with which we have to deal, the next step is to determine its magnitude. As enumerated in the first article, the following factors have to be taken into account:—

1. The increased pressure necessary in the feeders as the load increases.

2. The increased armature loss, and the increased excitation of the field magnets at heavier loads.

3. The slip or loss of pressure caused by the increased back action of the armature currents in the field magnets, and the increased self-induction, the latter meaning a higher rate of driving, though not necessarily directly loss of energy.

Let us proceed to determine roughly the magnitude of these effects in order as above.

1. *The increase of pressure required on the mains.*—This will depend on whether the system is high or low pressure. For an ordinary high-pressure system the pressure will not usually need increasing more than 5 per cent. if the standard is 2,000 volts, which is allowing an additional 1 volt, or 1 per cent., on the consumer's premises, 2 volts, or 2 per cent., in the secondary circuit from the transformer substation, and 2 per cent. in the high-pressure main.

If, however, a low-pressure three-wire system is used, the loss in the feeders may easily be 12 per cent. more at full load than in the daytime, making a 15 per cent. variation in all from dynamo to lamp.

Intermediate systems require intermediate variations; but we may fairly take it that at full load the pressure in the mains must be increased 5 per cent. in a high-pressure alternating station, or 15 per cent. in a low-pressure continuous one.

2 and 3. *The Reactions in the Generators.*—These depend somewhat on the class of generator used. As a rough approximation it may be taken that if the voltage of excitation—that is, the electric pressure across the field magnet terminals—is kept constant at all loads, the speed will have to be increased some 10 to 12 per cent. to secure equal voltage of current at full load as well as no load. This applies to alternators and shunt-wound continuous-current dynamos as used in central

* For first Article see *The Electrician*, September 14, 1894, p. 571.

Digitized by Google

stations, intended to be worked in parallel. For compound-wound dynamos working singly this reasoning will not apply, the particular feature of their design being that they should run at a given speed and produce nearly an equal or greater voltage at high loads.

From the above considerations we deduce the facts that in an alternating station, if the excitation is constant, the speed of the alternators must be increased about 5 per cent. for the mains and 10 per cent. for internal dynamo reaction, or a total of 15 per cent. at full load, and in a continuous-current station about 15 per cent. on the mains, and 10 per cent. for the dynamos, making 25 per cent. in all.

These figures can, of course, only be considered as approximate and liable to vary with circumstances; but still they suffice to define sufficiently the order of magnitude of the effects with which we have to cope.

It is desirable at once to point out, however, that the problem is not so difficult as it would appear at the first glance, since, if the excitation is increased at the same time as the speed, the pressure will go up as some power, say, about the square of the speed. If, therefore, continuous-current dynamos are excited from the omnibus bars when the voltage of them is raised the exciting current will increase also, so that to obtain the effect of 25 per cent. increase of speed alone we have only to actually increase the rate of driving about 11 per cent. In an alternating station with the alternators and exciters coupled, where we only require an increase equivalent to 15 per cent., the rate of driving only needs an increase of 7 per cent. Supposing, then, we wished to run an alternating station entirely without electrical means of control, we should have to arrange for engines to run at a constant speed, and to be capable of varying that speed some 7 per cent. or 8 per cent. while running; or, if the stations employed low-pressure continuous currents, then, under similar circumstances, the engines would have to be capable of 11 per cent. to 12 per cent. variation while maintaining their capacity for keeping the speed constant with considerable variations in load.

The above is what may be considered as the outside limit of the problem stated purely from the "steam" engineer's point of view; and there is certainly enough in it to set inventors of governors thinking. At the same time, it is doubtful whether it will ever be practical or desirable to depend on engine regulation entirely. At present almost the converse is the case—the engines are kept as nearly as possible the same speed, and the regulation is done electrically, and chiefly in the field-magnet circuits. I am, however, one of those who hold, that the amount of regulation in central stations should be the least possible if the customers are to be well served, and, secondly, that as much as possible should be left in the hands of the men who control the engines; that is, there should not be what there is in most stations at present, a dual control, the electrical part of which is often left in the hands of learners and apprentices, who, if not incompetent, are often without a due sense of responsibility.

ELECTRIC TRACTION BY ACCUMULATORS IN MINES.

M. Joseph Libert recently contributed to the Charleroi Section of the Association des Ingénieurs sortis de l'Ecole de Liége a Paper on the use of self-contained electro-locomotives in mines, in which he describes two very interesting applications of accumulators to underground haulage, the one at the Fond-Piquette Colliery, in the Liége district, and the other at the Amercœur Colliery, in the Charleroi district.

Accumulator traction, even above ground, has not yet been very successful in England; although on the Continent, at Paris and elsewhere, it is reported that cars are being worked at a profit, and it is asserted that the problem is solved as regards surface traction. M. Libert assumes this to be so; yet there are engineers in England who have had much experience with storage traction, and who do not view the problem as completely solved even for tramcars, much less for underground haulage.

Accumulators have also been tried in England for underground work, but in a very short time the bad condition of the rails proved to be fatal to success. Indeed, to give the cells the same chance that they have on the surface it would be necessary to remake the roads entirely and relay them with much heavier and more carefully laid rails than those obtaining in the majority of pits to-day. The question of gradients, levels, and curves has further to be considered, and would necessitate much modification.

M. Libert assumes that it is generally possible to lay out the main roads in such a way that the gradient should always be with the loaded trucks, and that the resistance to the empty ones up hill should be approximately the same as to the loaded ones down hill. This we do not understand. That it is possible to make very marked improvements in the main roads we admit, of course; but quite fail to see how the general trend of the roads can be altered to suit the conditions named in more than an approximate degree; or, indeed, how it is possible, even in opening a new seam, to fulfil them unless the workings are all to the rise, which cannot be the case always. Assuming, however, that the main roads are fairly well adapted, it is obvious that the coal must be carried at a very small cost per ton per mile, and if accumulator tramways find a difficulty in paying at a penny, say, per passenger per mile, it is difficult to see how the underground locomotive can pay when the cost of haulage must be less than this figure for a ton carried per mile. M. Libert gives the cost of haulage at the Amercœur Colliery with an accumulator locomotive at 0·75d. per metrical ton-kilometre, or, say, a little more than a penny per ton mile; while the cost of horse haulage at the same pit, but under different circumstances (whether more favourable or otherwise is not stated), is estimated by him at 1·5d. per metrical ton-metre, or, say, twice as great. These figures we believe to be much in excess of the cost of haulage in English collieries with stationary engines, the cost of which is from 0·25d. to 0·5d. per ton mile.

We cannot criticise these figures as applied to the collieries in question. They may be justified under the circumstances; but we are sure that, unless the cost can be further reduced, there is no probability of the self-contained locomotive obtaining a footing for general use in the place of horses; of course, they can never compete with stationary engines or with direct-transmission locomotives where the conditions admit of their use.

The two locomotives appear to be well designed, and to embody the experience gained at various pits. The Amercœur ones have four wheels with a wheel base of about 3·75ft., the over-all dimensions being: length 13ft., width 3·9ft., and height 3·77ft. The weight, with cells, is 3 tons 2cwt. 96lb.

The driving gear consists of spur gearing in the first transmission and chain gearing in the second. There is a platform at each end.

This locomotive is designed to haul a minimum of 300 trucks per ten hours in trains of 15 trucks each, the normal speed being about five miles per hour. The line is one mile 1,520 yards in length.

The second locomotive at the Fond-Piquette Colliery has two four-wheeled bogies with short wheel bases, the wheels being apparently of the same diameter as in the first one. The over-all dimensions are: length 14·95ft., width 3·28ft., height above rails 4·34ft. There is a platform at each end. The gearing consists of a single transmission by spur gearing. The total weight is 4 tons 8cwt. 44lb. It is designed to haul 400 trucks per ten hours, each train consisting of 20 trucks, the speed being about five miles per hour, and the road about one mile in length.

This locomotive, although nearly 15ft. long, will turn round a curve of 19·6ft. radius.

The peculiarity of both of these haulage planes which renders them suitable for the use of locomotives appears to be the great length and the small tonnage carried over them in the working shift of ten hours.

The accumulators form the most interesting part of the equipment. They are of the Julien type, having plates 11·8in.

Digitized by Google

by 7·8in. Each battery comprises 36 cells, having a storage capacity of about 49-H.P. hours, which is sufficient to give eight hours continuous working at a rate of 6 E.H.P. M. Libert estimates this as equivalent to an effective mechanical tractive power of about 4·25 H.P. Granting these figures, which appear to be reasonable, it is evident that the locomotives are of small capacity, and are only adapted for working under favourable conditions as regards rails and load. Indeed, one of the weak points with self-contained locomotives is that they have no reserve power for accidental increments of the normal load, which in all cases must inevitably affect the speed, and in some cases disastrously, with, of course, serious damage to the cells.

The method of mounting the cells in a spring carriage on the top of the bogie frames, which of course have their own springs, is excellent, and must do much towards lengthening the all-too-short life of the plates. Anxious as we are to see accumulator traction established on a sound electrical and mechanical basis, we cannot say that we have much hope that these self-contained locomotives will stand the test of mining work for long. When the problem has been successfully solved for tramcars, then we may expect to find a solution for underground haulage; but the cells will have to undergo radical alterations before even a measure of success is possible, in our judgment.

IRON WIRES UNDER ELECTRIC OSCILLATIONS.

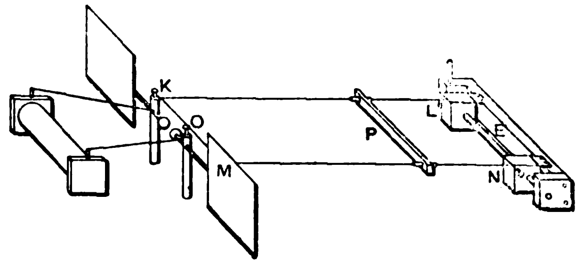
In the October number of the *American Journal of Science* a Paper from Prof. John Trowbridge appears on the change of period of electrical waves on iron wires, followed by another by Mr. Charles E. St. John on wave-lengths of electricity on iron wires. Both these Papers go to show that the question whether the magnetic properties of iron are called into play under extremely rapid alternations of the magnetising forces must be answered in the affirmative. The method of investigation employed by Prof. Trowbridge was the same as that used for the determination of the damping of electric waves on iron wires. A Leyden jar was discharged through iron and copper wires respectively, and the resulting spark, spread out by a revolving mirror, was photographed. The times of oscillation were in each case referred to a standard "time-circuit," so as to eliminate the errors due to changes in the angular velocity of the mirror. Trial circuit of the same geometrical form were arranged as follows:—A cylinder of very porous wood 11·5cm. in diameter, and 15cm. long, was boiled in paraffin, and a spiral was cut upon its surface with the turns 1cm. apart. On this cylinder and in these spirals the wires under examination were wound, thus obtaining exact geometrical similarity combined with good insulation. Several hundred determinations were made with wires of different sizes. With iron wires larger than 0·0312in. in diameter no marked change in period could be noticed. If a great number, however, of photographs were measured, an inconstancy of ratios was noticed which never appeared when the copper circuits were compared. The most marked changes in period were obtained with iron wires of 0·0312in. in diameter. With distances on the "time-circuit" between two successive serrations on the photographic record of 6·08mm. and 6·00mm. respectively; the distance for the iron wire was 3·7mm., and for the copper wire 3·4mm. A large number of similar results show that the wave-lengths sent out by a vibrator on iron wires differ in length from those transmitted along copper wires of the same geometrical form.

Mr. C. E. St. John, working in the Jefferson Physical Laboratory, arrived at the same result by an entirely different method.

A Lecher wire combination was deprived of the secondary discs near the vibrator plates, which complicate the simple Hertzian wave system. In order to be able to adjust the length of the wires at will, the author finally adopted the arrangement shown in the diagram.

L K M N is a copper or iron wire with free ends at L and N. These ends were inserted in small copper boxes 10cm. square and 4cm. thick, mounted upon the wooden bar E by insulating supports. Within the boxes were wooden bobbins fixed on a hard rubber axle, and each capable of holding 10m. of the largest wire experimented upon. The bar E was fastened to a wooden support resting upon a car which ran on a wooden track extending the entire length of the room. A specially-designed interruptor for the induction coil was driven by a small electric motor, and made about 25 breaks per second. The plates of the Hertz vibrator were 40cm. square and fixed at 61cm. apart.

The induction coil was 53cm. long, 19cm. in diameter, and was excited by the current from five storage cells. A sparking distance of about 6mm. was most effective in producing oscillations in the secondary circuit, which was arranged to give maximum resonance. For each observation, the interruptor was set in action, the circuit was closed through the induction coil, and an observation was taken of the first swing of the needle connected with the bolometer, whose terminals are shown at P. The bolometer was that described by Paalzow and Rubens, in which the heat caused by oscillating currents alters the resistance in one arm of a Wheatstone Bridge and disturbs its balance. The terminals consist of two capillary



glass tubes set in a frame of wood, which slide over the wires to be explored, and around each tube is wrapped by a single turn one of the wires leading to the bolometer. A series of maxima and minima were thus obtained from which the wave length could be determined. Such observed half wave lengths were the following:—

Copper, diameter	0·1201 cm.	255·6 cm.
Iron, „	0·1186 cm.	251·6 cm.
Copper, diameter	0·07836 cm.	251·6 cm.
Iron, „	0·07850 cm.	246·8 cm.

The capacity per unit length being the same for wires of the same diameter, the shortening of the wave length when iron displaced copper must be caused by an increased self-induction due to the magnetic properties of the iron. This implies that the magnetisation of iron can be reversed 115 million times per second. This reduces the "time lag" of magnetisation to very narrow limits, if forces of such duration can magnetise the iron.

Mr. St. John thus sums up his conclusions:—

1. The self-induction of iron circuits under very rapid electric oscillations (115×10^6 reversals per second) is greater than that of similar copper circuits. The change in self-induction varies from 3·4 to 4·3 per cent. in the present investigation, and increases with decreasing diameters.

2. The increase in self-induction produces greater damping and a shortening of the wave length of 1·5 to 2 per cent.

3. The permeability μ of annealed iron wires under this rate of alternation is about 385.

4. For oscillations of the same period, the wave length along parallel copper wires varies directly with the diameter of the wires. Range of wires used 0·03915cm. to 0·1201cm. The maximum decrease observed is 5 per cent.

Franklin Institute Awards.—The Committee on Science and the Arts of the Franklin Institute have just announced the awards of the John Scott Legacy Premium and Medal to Clement Payen for his inventions in connection with the chloride electrical storage battery, and to Alexander Jay Wurts for improvements in lightning arresters.

ACCUMULATORS.

While steady progress has been made during the last thirteen or fourteen years in the construction of dynamos, motors, lamps, and the minor accessories of electrical work, the accumulator, though somewhat improved, remains in an undeveloped stage. Success has been achieved chiefly in that type of accumulator which is used for supply stations, and even here it is a long way behind the dynamo as an economical, durable and efficient item of plant. In first cost, accumulators are a serious burden to a station; taking the normal rate of discharge, the cost is about four to six times that of a dynamo of the same output. The durability has been considerably improved; but there seems to be some doubt about the constancy of the storage capacity. The efficiency is lower than that of an inferior dynamo or motor, and there is no improvement with larger sizes. But, for all this, we believe that many of the promises made for secondary batteries may yet be fulfilled, and that improvements will be made, probably in special directions for special purposes. The slowness of this development in the past has no doubt been due to the fact that an experiment with an accumulator is a matter of months. An improvement in dynamo construction can be tested as soon as it has been made, and the result can be worked out within a few minutes of the test. A number of modifications and further tests of a machine may, perhaps, be carried out and completed in the same day; but with a battery a year or eighteen months of regular work must elapse before a definite opinion can be formed of its merits.

In dynamo design there are two distinct elements, the electrical and the mechanical. There has been an immense amount of discussion about the former, and a great neglect of the latter. Many dynamos have been built which have run for years without trouble, simply because they have been built by mechanical engineers. Others, giving perhaps a larger output for their weight and a higher efficiency, are continually breaking down because they have been designed by electricians. In the construction of accumulators similarly, there is the chemical and the mechanical element. Much attention has been given to an explanation of the chemical action, but there has not been much fertility of invention in this direction. The chloride and the alkaline batteries are the only two noteworthy departures from the lead peroxide original. The success of several types of battery is due to their mechanical construction. The retention of the paste, the prevention

Digitized by Google

of buckling, the use of separators, and the arrangement of joints and connections have contributed much more to success than theoretical investigations of the reactions which go on, or which ought to go on, within the cell.

The accumulator came to us from the Continent, and it is there that it has been most successful. The Tudor, Julien, and Laurent-Cély or chloride battery are used to a very large extent by our neighbours, and the last of these has been recently introduced in this country. The patent monopoly may have had something to do with the lack of progress in England; but next year will see the expiry of the earlier patents, and we shall then see whether the pasted plate receives attention from manufacturers who have hitherto used modifications of the Planté battery.

Next to supply work, traction seems to be the most important use to which accumulators may be applied. The problem at first seemed so easy, but it was attacked by men who knew little about mechanical construction and nothing about tramways. Even the late Mr. Reckenzaun, one of the few competent men who seriously concerned themselves with it, cannot be said to have seen success, though he may have contributed largely to a success which will one day be made. The Julien battery seems to have the best result up to the present, and in another column we print an article on electric traction in mines, where this battery has been used. The difficulties of electric traction are merely mechanical. Given a decent motor, and putting aside for the moment the question of corrosion of earth returns, a mechanical engineer will make an electric railway or tramway succeed if the conditions of success are present. It is doubtful if overhead wires will be popular in this country, and it is certain that the high speeds used in America will never be tolerated here. If electric traction is to become common on tramways, it is probable that accumulators will be used. Because success has been achieved in Paris and elsewhere, we cannot assume that the same system is applicable to our roads; but a service which suits the requirements and the pocket of a Frenchman is more likely to suit an Englishman than the systems described by Mr. Wilkinson in the Paper which is concluded in our present issue.

REVIEWS.

Les Oscillations Electriques. By H. Poincaré. (Paris: George Carré.)

The above work consists of an exposition of Maxwell's electromagnetic theory, with special reference to the researches on electric oscillations carried out by Professor Hertz and his followers. It is a reproduction, with additions, of the lectures given by the author to his students during the session 1892-3. The rapidity with which these lectures have been worked up and published is characteristically French. We have not heard of any English professor who publishes his lectures year after year as M. Poincaré seems to do. Those who have kept themselves in touch with the literature to which the researches of the late Professor Hertz has given rise, will remember the two highly valuable works on electricity and optics which Professor Poincaré published in 1890 and in 1891. The first of these volumes dealt with Maxwell's theory, and the electromagnetic theory of light; and the second with the analogous theory of the late Prof. von Helmholtz, and also with the experiments of Hertz on oscillations. The present volume, like the others, extends to 300 pages or more; but, although travelling over much the same ground as the other two, it is by no means a repetition of their contents. In fact, even the fundamental equations are considerably altered owing to the adoption of a different system of notation. In the former volume Maxwell's symbols were adhered to with almost the same strict fidelity as is to be found in Professor J. J. Thomson's recently published sequel to Maxwell's work. In the present book, however, Prof. Poincaré has endeavoured to modify the equations, so as to make the connection between the symbols and experimental quantities more apparent than is the case when one tries to apply Maxwell's equations directly to explain Hertz's results. It is interesting to note that the author has found it best to reproduce Hertz's notation. The chief difference between this and Maxwell's consists in the introduction of a quantity, A, into the equations. This quantity is ultimately shown to have a definite connection with the velocity of undulatory electromagnetic disturbances in air, and has thus a distinct physical meaning. One of the advantages of introducing it into the equations is that it enables the symbols for specific inductive capacity (electric or magnetic), to be regarded merely as numbers. In Maxwell's theory, as explained in his book, the symbols κ and μ for these quantities cannot be regarded as mere numbers, because they express the ratio between the induction and the inducing force; that is, between the flux (electric or magnetic), and the corresponding force producing it. Maxwell's book was, however, not concerned much with the explanation of oscillation phenomena, the existence of which had not at that time been experimentally established; and, when only a steady electric, or a steady magnetic, state is under consideration, only one of the symbols μ or κ enters the equations. When this is the case it is possible, by arbitrarily altering the dimensions of the quantities involved in the equations, to look upon either μ or κ (but not both) as a mere number, expressing the ratio of the inductivity of the medium, to that of air. This ratio is, of course, unity in the majority of cases, where the medium considered is air itself; and Maxwell accordingly omits the inductivity symbol altogether in many of his equations. This is most confusing to the student who endeavours to apply the theory to the phenomena of oscillations, for it is necessarily some time before he can distinguish the cases where the omissions have been made, from those in which the inductivity symbols do not naturally occur. It is a difficulty which appears to be of very little moment to the merely mathematical reader; but to the physicist it is an all important matter. This source of confusion is entirely avoided in the present book.

To properly appreciate this work the reader must be well up in the mathematical theory of electricity. Poynting's theorem about the transfer of energy in the electromagnetic field occurs in the very first chapter; and the second chapter, after briefly describing the work on electric oscillations done previous to that of Hertz, is soon devoted to the mathematical discussion of the exciters and resonators used by that scientist and his followers. Although Hertz found it comparatively easy by his method to establish the existence of electric undulations, and to show that they were the same in general characteristics as light waves, it did not prove a simple matter to show that the velocity of these two kinds of disturbance was the same. An error in calculating the capacity of his apparatus misled Hertz to a conclusion which he was very loth to accept; viz., that the velocity of light was different from that of the electromagnetic waves. The most careful experimenting only seemed to confirm this view, although it was in direct opposition to the conclusions of Maxwell's theory. It was not until Prof. Poincaré pointed out how the error in calculation arose that the seeming contradiction was explained. The critical examination to which the author of this work subjects the theory of the capacity and self-induction of apparatus such as that used in these experiments, is specially worthy of attention. Hertz stated explicitly that the theory he gave was only a preliminary one; and, indeed, the slightest consideration shows that when electrical disturbances are occurring at the rate of 100,000,000 per second our ordinary notions of capacity and self-induction must be greatly modified. That this is the case is shown by an elaborate investigation of the apparatus used by M. Blondlot. The third chapter is mainly concerned with the mathematics of Hertzian oscillations; but it also contains some valuable observations in reference to the decrement of the oscillations of a Hertz exciter. The vexed question of multiple resonance is next discussed at length, and the experiments of Sarasin and de la Rive, Blondlot, Perot, Bjerknes Jones and Rubens,

Digitized by Google

whose researches bear on this matter, are described. The new phenomena discovered by Messrs. Sarasin and de la Rive are shown by these experiments to be due to the oscillation of the vibrator subsiding more rapidly than those of the receiver. The study of the decrement of the oscillator is important, not only because the damping affects the character of the resonance, but also because it determines the sharpness of the resonance effect.

The results obtained by Hertz in many of his earlier experiments were complicated by reflections occurring on the walls, &c., of the rooms in which the observations were made; and, although Hertz was the first to demonstrate the existence of these reflections, he did not foresee their influence on the tests in question till after the majority of his experiments were made. The actual results obtained were always faithfully recorded, and tended to confirm the erroneous conclusion that the velocity of the waves when traversing air was not the same, as when moving along metallic conductors. The proper interpretation of some of these experimental results is still problematical. Prof. J. J. Thomson has shown in his recent work how the apparent difference in the velocities can be accounted for by side reflections, and Prof. Poincaré, in the fifth chapter of his book, devotes a good deal of attention to these obscure points, and refers to experiments by more recent workers. Another chapter is added, describing the various experiments which have been made on the propagation of electric waves in dielectrics other than air. The various methods of determining specific inductive capacity by means of electric oscillations, such as those used by Rubens, Arons, J. J. Thomson, Lecher, Blondlot, &c., are described and criticised from the theoretical point of view; and the results which these experimenters found are compared with those which have been obtained by older static methods. The book concludes with a critical discussion of Hertz's celebrated memoir on the fundamental equations of the electrodynamics of moving bodies.

The eminence of the author of this work renders superfluous any testimony to its ability. The student will find here the most complete account yet published of the experimental work, on electric waves, to which Hertz's researches have given rise; and the description is, moreover, accompanied by a fuller theoretical criticism than is to be found in any other book with which we are acquainted. The book should certainly be included in the library of every specialist on the subject.

Dynamo Attendants and their Dynamos. By A. E. Gibbings. (London: S. Rentell. 1894.)

The author of this little book commences by lamenting that "the men who look after the dynamos of a private electric lighting plant are so seldom well acquainted with the rudimentary principles of the machines in their charge," has discovered that the fault is due to the absence of suitable literature, and proceeds to supply the want. It may be doubted if the generality of dynamo attendants, even in private dynamo rooms, do require the kind of information provided by Mr. Gibbings; but there are plenty of amateurs who may find it interesting and instructive reading of its kind. A dynamo attendant who needs to be told, for example, that "The spindle goes right through the bearings, commutator, armature and pulley, and should run perfectly true and be a good fit," ought to vacate his post on the instant. On the other hand, it probably will be news to most dynamo attendants that in suddenly altering the resistance of a shunt machine "there is a danger of short-circuiting the dynamo, causing too much current to go around the shunt and fuse it." It is not very consoling to be told that sparking due to overloading "may partly be due to earth contacts in the external circuit; and if so, will very likely take some time to discover;" and how does the dynamo attendant like being told that the speed indicator "is to form a check on the watchfulness of the dynamo attendant," and "should be fastened with a padlock so that no tampering" can take place? In coupling machines in series or parallel, "the dynamo attendant may assume the methods to be analogous to those he would adopt when connecting up a primary battery"; but he must not be over sure of this, as he must "take into consideration the different forms of winding," and "it must be ascertained beyond doubt that the increased current which will traverse the circuit will not cause serious damage." With such vague phrases does the author supply the place of definite information and direction; and in this inane and insipid style he offers to his readers a combination of platitudes and error.

The Practical Designing of Structural Ironwork. By Henry Adams. (London: E. and F. N. Spon. 1894.)

This is a truly admirable work. We do not remember to have met with a clearer, more concise and practical treatise on structural ironwork design. Not alone is the information eminently practical and to the point, devoid of irrelevant theory and useless padding, but the author's method of arranging it is the best possible way of conveying the instruction which is intended. We think that this method might with advantage be adopted by writers upon other technical and engineering topics. Mr. Adams plan is to select a series of actual problems, arranging them in progressive order, and then, while working these out numerically, to intersperse the solution with such remarks and generalisations and practical hints as would be likely to be of use to the reader in the practical working out of similar problems. First, we have a problem involving the design of a "small cast-iron girder," then a "flitched beam," then some observations on riveting; and so on, through "cast-iron columns" and "story posts," to such more complicated structures as a "lattice girder bridge" and a "wrought-iron roof truss." The author evidently is thoroughly proficient in his subject and, what is equally to the purpose, he understands how to impart his knowledge to his readers. Bridge and roof design are not subjects which are closely affiliated to electrical engineering; but to anyone who may desire to obtain information on these subjects we could not recommend a more useful, or a more readable work than that one before us in which Mr. Adams adds another to his already lengthy list of practical engineering treatises.

Electric Lighting Plants: their Cost and Operation. By W. J. Buckley. (Chicago: W. Johnston Printing Company. 1894.)

This little book claims to consist of "data compiled from station reports of electric lighting plants employing overhead circuits, with suggestions pertaining to the information usually desired by the non-technical purchaser"; or, in other words, its purpose is "to give to intending purchasers of lighting plants such details as may aid them in forming a fair estimate of the cost of construction and operation of their proposed station." It will be seen, then, that the writer starts with a definite and laudable object in view; but it cannot be said that he quite achieves its end. Only American practice is considered; but even from an American point of view the scope is narrow. For the writer, after telling us that he is "neither electrician, engineer nor expert, but a salesman," goes on to confess that "in a noble effort to deserve his salary" he has refrained from mentioning other lighting apparatus but that made by the Company whose salesman he is. As an instructive spectacle of frankness and modesty, all this may be very well; but it is hardly calculated to inspire confidence in the reader. However, the writer is not as bad as he paints himself, and his book contains a great deal of useful information of a general character, including a number of tables and curves showing the weight, size, cost, efficiency, &c., of engines, dynamos, transformers, shafting, belting, &c., and it suffers only in "errors of omission" from having been restricted to the wares of only one electrical company.

"A Dictionary of Electrical Words, Terms, and Phrases." By E. J. Houston. Third edition. (New York: The W. J. Johnston Company. London: "The Electrician" Printing and Publishing Company.)

The rapid circulation of this compilation has necessitated the issue of a third edition in an unrevised form, but with copious additions in the form of an appendix. Our opinions of this work are expressed in our review of the second edition, which will be found on page 510 of Vol. XXIX. We regret that as the defects, which were there pointed out, still exist, we are unable to alter our opinion of the main body of the work. With regard to the appendix, this is both extensive and exten-

Digitized by Google

sively cross-referenced, perhaps too extensively, indeed. What progress the profession must have made (at any rate, in the coining of words), if we may judge by the 105 pages of appendix. It is true that we have heard of "Spark, Electric," before, and are surprised at its absence from former editions. But the words "trega," "magnetine," "magnetician," "electrologist," &c., are new to us, and they doubtless mark important advances in the science. The first-named is "a prefix proposed by Houston and Kennelly for a million million or 10^{12}." The appendix, however, notwithstanding that it contains many definitions which might safely have been dispensed with, is on the whole a very useful addition to the work.

Tables and Formulas for Electric Street Railway Engineers. By E. A. MERRILL. (New York: The W. J. Johnston Company, Limited. 1894.)

In so far as this consists almost entirely of tables, without any compressed text-book stuff, this is almost an ideal pocket-book. But for the fact that the electrical and mechanical data are in American units and gauges, and are, therefore, only readily useful in America, the ideal would, perhaps, have been attained. The book is small and light, and strongly bound; the print is clear, the matter is well arranged, and consists almost exclusively of tables and formulæ; there are no useless and inartistic pictures, so absurdly out of place in a pocket-book of this kind; and there is no theorising. Everything is short, terse, and to the point; and little, if anything, legitimately connected with street railway work has been overlooked. There is a great deal in the book which might prove useful to an English tramway engineer.

Construction des Lignes Electriques Aeriennes. By A. BOUSSAC and E. MASSIN. (Paris: Gauthier Villars et Fils.)

Shortly before his death in January, 1893, M. Boussac, Professor of Construction at the École Professionnelle supérieure des Postes et Télégraphes, decided to publish his course of lectures there in book form. The present volume comprises such lectures, nineteen in number, as were in manuscript or in type at the time of M. Boussac's death, together with six more completing the course, from the pen of M. Massin. This work is a clear and methodical, though a somewhat too mathematical, exposition of the leading principles of overhead telegraph line construction. It should form an excellent supplement to the elaborate telegraphic treatise by M. Thomas, recently reviewed in these columns, in which the chapter devoted to line construction was perhaps unduly brief.

NOTES ON ELECTRIC TRAMWAYS IN THE UNITED STATES AND CANADA.*

BY H. D. WILKINSON.

(Concluded from page 729.)

I found, on the other hand, that some of the more recently-planned power stations were equipped with direct-coupled plant; and the tendency of advanced practice in America, if one may take the plant at the World's Fair as an indication, was certainly towards direct driving. The General Electric Company, who completely equipped the very successful elevated electric railroad of three miles in extent through the Exposition grounds, used for the most part generators coupled both to horizontal and vertical engines, while the Westinghouse Electric Company supplied power to the moving sidewalk from a large dynamo taking the place of a flywheel between the high and low-pressure sides of a cross-compound horizontal engine. This Company also exhibited a 160-H.P. generator direct-coupled to a Westinghouse high-speed engine, such as regularly used in their power stations.

I also saw well-arranged direct-driven sets in the power-houses at Milwaukee and Cleveland. At the former place there was a very large Edison plant, with boilers on an upper floor and engines below. The engines were of 600 H.P., vertical, triple-expansion, condensing, each driving two 200-kilowatt generators. At Cleveland the power-house of the Cleveland City Railway Company contained four vertical triple-expansion condensing engines, by the Globe Manufacturing Company, of Cleveland, of 560 H.P., three driving two 190-kilowatt four-pole generators each, and one driving one six-pole generator, the maximum output of the station being 2,800 amperes at 500 volts. These engines were fitted with Joy's valve gear, controlled by a small centrifugal governor through the medium of a hydraulic valve.

Dynamos were very carefully insulated from earth, in some cases by half an inch of sulphur under the rails, and in all cases by wood under the bed-plate, and where direct-coupled the coupling was insulated. This precaution is necessary where overhead wires are used, on account of lightning, to prevent a side flash between coils and framework. When a flash does pass by the machine, the damage is caused by the current of the machine following up the flash. The "magnetic blow-out" and "air-blast" arresters are being supplanted by Wurts' water tank arrester, in which there is no spark gap. The well-known action of lightning in choosing to flash from coils to frame instead of through magnet and armature coils to earth, on account of self-induction in the latter, is utilised in preventing its reaching the machine at all. Coils are placed in the line circuit—a sufficient number being in multiple to carry the current—and from these at intervals connections are tapped to carbon rods dipping into water in a tank. Lightning is checked by the induction of the coils, and discharges by the rods and water to earth. By the use of running water the normal loss from generators is reduced to a very small amount; and by using a small branch from the city water mains, with overflow pipe for this purpose, the additional advantage is gained of a good earth.

I found that a good deal of power was tapped off the 500-volt tramway circuits for supplying private motors. On the Cleveland Electric Railway Company's system there was 350 H.P. taken off for this purpose, the motors varying in size from one-eighth to 25 H.P. The tariff charged was 20s. per month per horse-power

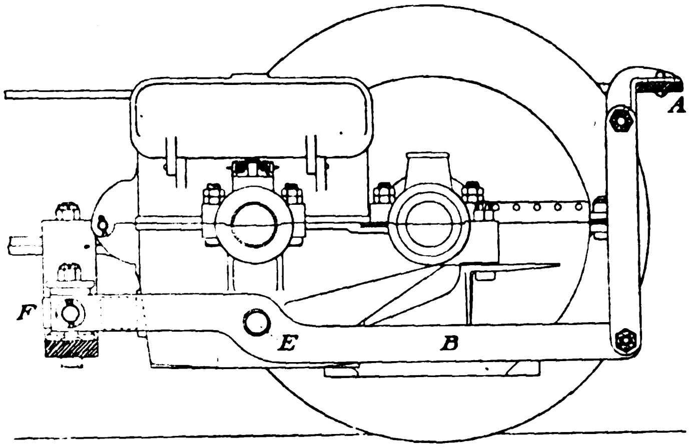

FIG. 19.—Side Suspension of Motor.

for a 3 H.P. and over, or at the rate of 4d. per horse-power hour, the horse-power being averaged by a portable meter kept on the circuit for a given time.

Improvements have been made in the design of street car motors, their attachment to car trucks, and in decreasing their weight for a given output. Through the courtesy of the General Electric Company I am able to give a few particulars of their latest type of 25-H.P. motor, known as the "G.E. 800 motor." This name is stated to be given to it on account of the drawbar pull exerted by the motor being 800lb. on ordinary street tracks, with 33in. car wheels, the usual single reduction gear, and rated current. The dead weight has been reduced to 1,450lb., or 730lb. below the former standard type of the same power, viz., the W.P. 50 (waterproof motor). Next to reducing the weight of the motor *per se* is the requirement of reducing dead weight on the axles and distributing it over the car. By the usual end suspension about half the weight is carried by the axle, and half by a cross-bar resting on springs; but by a new arrangement with side-bar suspension (Fig. 19), the whole of the weight is taken off the axle. The side-bar B takes the weight of the motor at the trunnion E, and is itself supported by link bars bolted to the frame at the back A and by six springs in front at F, four of which take the weight, and two resist upward pressure. The wear and tear of the track is by these devices considerably reduced, and the running of the cars improved. The motor is enclosed in a cast-iron frame, in two parts hinged together, the same forming the field. There are two field coils, one in the upper and the other in the lower portion of the field; and, as these are wound to give similar poles, two additional consequent poles are formed between them, making a four-pole machine. The armature is cross-connected, so that only one pair of brushes is used; and these, with the upper field coil and armature leads, are fixed inside the upper half-frame, and swing back

* This Paper will be discussed early in the course of the next session of the Institution of Electrical Engineers.

Digitized by Google

with it. The iron of the field is, of course, to earth, and therefore special care is necessary to insulate the field coils; but the chance of a fault is minimised by coupling the coils to the earth return, in which case they can only vary by a few volts from the potential of the frame itself. The axle gear, which runs in an oil chamber, is arranged for a speed reduction of 4·78.

The latest type of Westinghouse motor for street cars is built in a cast-iron horizontal frame, on which are hinged the upper and lower field magnets, so that the armature can be got at from above or below. There are four field poles, with as many coils. The armatures are drum-wound, each coil being wound on a former of the size of a quarter the circumference of the core, then taped, and slipped into its place between the teeth of the core. The wires composing the coil are laid so as to form a flat strip, which goes in edgewise between the teeth and lies flat at the ends of the drum, so economising space. The whole is then covered with waterproof material.

There are various types of "controllers," or combination switches, for putting the two motors on a car in series and parallel. The switch handle has from five to ten notches, giving different grades of speed. The first, or starting, position puts the motors in series through resistances; the succeeding steps reduce the resistances, shunt one motor out of circuit, and finally put both in parallel. There is also a side lever operating a cylinder of contacts for reversing the motors. I tried the experiment on one of these controllers of making the motors act as an electrical brake. Getting them first up to full speed, the controller was put back to starting position, current switched off, motors reversed, and then put in parallel again. The slight difference in excitation between the motors then caused one to act as a generator and drive the other, making a very powerful and quick-acting brake. A single switch might be employed which would effect these changes, and so prove an important aid to the mechanical brake in an emergency.

In Philadelphia I found very few streets with overhead wires, and learnt that an active policy had been pursued by the City Electrical Bureau towards the placing of all electric wires underground. One overhead trolley line was in operation, but the feeder cables were all in underground cement-lined conduits. Mr. D. R. Walker, chief of the Electrial Bureau, informed me that he, in company with the Director of the Department of Public Safety, had examined into the systems of electric traction in other cities, with the view of employing the most suitable for the city of Philadelphia. He referred me to his report, which summed up as follows:—

"The overhead system, or electric propulsion of street cars is, in my opinion, better fitted for small towns or villages, or to connect the same, or for the suburbs of a city such as our own; but when it comes to introduce electricity as a motive power in the heart of a large city, the circuits conveying the power for the same can, and should, be placed beneath the surface of the street. It has been effectually proven a success in Chicago, and is now being introduced to a large extent in Washington, D.C.; and any new privileges asked for in this direction should be granted only on condition that all the wires used for such a purpose should be placed underground. The only difference between the overhead and underground systems is in the matter of cost, which is but a secondary question when the safety and comfort of our people, and maintaining the beauties of our thoroughfares, are concerned. Again, a more reliable service can be maintained underground than overhead, as it would be free from interruptions caused by fire, falling of wires, or the action of the elements. The franchises so granted are immensely valuable, and while they are being issued the interests of the city should be taken into consideration, and provision made underground for its electrical systems and for the lighting of its highways."

I may mention incidentally that the city authorities use, or own and rent to private companies, about 25 miles out of the 150 miles of underground conduit laid. I refer here to conduits constructed for the reception of electric cables and feeders, not for tram-car propulsion. The wires owned by the city are for telegraph and telephonic communication from the City Hall to fire and police stations and street call boxes, of which there is a most complete system, and for the electric lighting of the streets. The city contracts with lighting companies to supply lamps and current only, posts and cables being erected and laid by the city. I was very much impressed with this imposing and beautiful city, and with the system of control exercised in the interest of the citizens over all electrical undertakings by the Electrical Bureau.

Of the 12,000 miles of tramway in the United States and Canada, about 7,200 miles are operated by electricity, and 3,500 miles by horses. In conclusion, I need only remark how well adapted electric traction is to the wants of the people. Following the ordinary highways, where business is done and people congregate and travel to and fro, tramways afford at once a means of locomotion that is readiest to hand with least trouble to the traveller. For short distances, people will not go out of their way to get on the railway, or climb steep staircases to elevated roads, provided that the street tram-cars travel at a reasonable speed, with minimum delay. For the latter desideratum a modification of the American practice in cities of not stopping between "blocks" might be adopted, while for a reasonable speed we must look to other means of propulsion than horses. The cable system is very suitable in certain localities, such, for instance, as on straight and hilly roads; but the wear and tear of cable is enormous on curves. Steam is unsightly and obnoxious. Electricity affords at once rapid and noiseless travel, quick control, with small wear and tear, and the current can simultaneously be utilised for heating and lighting the cars. As a means of travel, I have not experienced in the States anything so pleasant as their well-lighted and fast-moving electric street cars; and I cherish the hope that ere long this public boon may be extensively put into action along the streets and lanes of our own country.

THEORETICAL AND EXPERIMENTAL INVESTIGATIONS ON THE VISUAL SENSATIONS AND ON PHOTOMETRY.*

BY ANDRÉ BROCA.

In their photometric investigations, first Bouguer and afterwards Masson were struck by the fact that the eye perceives a difference between two luminous fields when this difference has a certain value dependent upon the luminous intensity originally common to the two fields. It was this remark that formed the starting point of Weber's and of Fechner's attempts to find a relation between the magnitude of the visual sensation and that of the excitation. Fechner's law was at first accepted in a general way; but to-day there seems to be reaction, and many individuals appear to hold the belief that it is impossible that a function connecting sensation with excitation should exist.

The retina is a machine which transforms the undulatory energy, when its wave-length is comprised between certain limits, into another form, the nature of which is quite unknown, and which physiologists call *nervous influx*. This is propagated by a conductor, the optic nerve, and impresses itself upon the cerebral surface at a clearly defined spot, the occipital lobe. Is it possible to disentangle from the midst of these complex phenomena a law connecting the sensation with the objective cause? Certainly not, unless we carefully define the condition of the organs at the moment of the impression, for the effect of the impression evidently depends on the degree of fatigue of the various organs, and this latter itself depends upon two causes: the impressions previously received, and the state of the circulation which allows of the reconstitution of the organs. But, owing to the constant change of the organism and its reconstitution by means of the materials brought to it by the blood, the state of the visual organs under the influence of a definite excitation tends to a definite limit.

But what is the nature of the connecting function? Fechner gave a first approximation, taking his stand on the Bouguer-Masson law and the following hypothesis: When the eye distinguishes two fields it is because the increased sensation due to the difference of illumination has attained a constant value.

The first thing to do is to verify Fechner's hypothesis, and this is what I have done, relying on certain anatomical data and some experiments indicating the part played by each of the two eyes in binocular vision. I hope to show that the sensations due to the two eyes are added.

The organ of vision may, in fact, be compared to an installation for the transmission of energy to a distance. The undulatory energy actuates a generating apparatus, the retina; this transmits *viâ* the optic nerve the energy in a form quite unknown, but called *nervous influx*. This is received by a well-defined portion of the receiving machine, the brain, and the brain under the influence of this impulse gives rise to the psychical act of perception. There are, therefore, two generating and two receiving machines. The relative values of each of these cannot be known *a priori*, and we know that, at any rate in the case of the cerebral lobes, the operations need not be the same. The two receiving apparatus which ultimately produce the sensation are probably of unequal efficiency; consequently, we cannot conclude from the fact that because two eyes are concerned the two sensations are added, except upon one condition—namely, that the nervous influx produced by each of the two eyes is equally divided between the two receivers; that is to say, between the two cerebral hemispheres. This, in fact, is what actually takes place in the case of the fibres issuing from what the anatomists call the yellow patch. Numerous experiments prove that a crossing-over effect occurs for the bundle of nerves issuing from the patch, at a spot called the *chiasma of the optic nerves*. We may, therefore, say that the sensations of the

* Abstract from the *Journal de Physique*, May, 1894.

Digitized by Google

two eyes should be added. If, therefore, for example, the right eye makes use of $1/\alpha$ of the luminous energy emitted by unit surface, whilst the left eye utilises $1/\beta$, the two eyes together will utilise $1/\alpha + 1/\beta$. Direct experiment verifies this qualitatively. Unfortunately, measurement is impossible, and we must content ourselves with subjective estimates.

Look with one eye at a uniform well illuminated white surface, and interpose an opaque screen held at arm's length, so as to conceal a portion of the illuminated surface. The screen being sufficiently far off we may regard the surface as one divided into two uniform fields, one bright the other dark, the zone over which the screen impedes the complete utilisation of the pupil being very small. It is confounded, indeed, with the shady zone due to diffraction. If at this moment the other eye is opened, one sees very clearly a very great difference in intensity between the field seen with both eyes and that seen with a single eye. This observation is occasionally delicate, for, in fact, observers who have one eye decidedly inferior to the other easily miss the sensation.

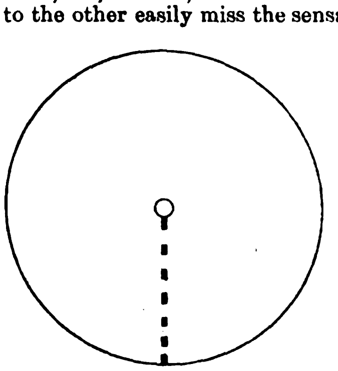

FIG. 1.

I made some measurements of this difference by means of a slightly modified Rumford photometer. I placed behind the photometer a screen having a hollow for the nose, and separating the two luminous fields. Placing the forehead and the nose behind this screen, the left eye only sees the left field of the photometer, and the right eye only the right side. The illuminated fields stand out against a dark background. In this way I obtained the following result: The right-hand field being illuminated to the extent of 0·4 carcel-metre, the left gave the same impression for an illumination of 1 carcel-metre. Therefore, for equal illuminations my left eye gives me an impression $2\frac{1}{2}$ times feebler than my right.

These experiments, it seems to me, establish the law I enunciated; that is to say, that the sensations of the two eyes are added.

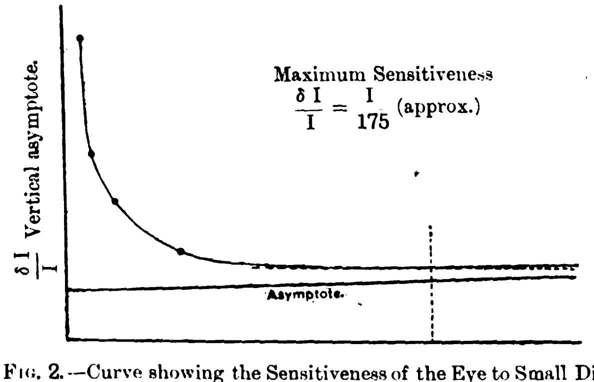

FIG. 2.—Curve showing the Sensitiveness of the Eye to Small Differences of Illumination as a Function of the Illumination. (Gas Lighting.)

I supplemented this experiment by another with the Masson rotating disc with black dots (Fig. 1). I looked at such a disc, and noted the last rings visible with both eyes and with each separately. The motion of the disc was derived from a small dynamo, and was very rapid and very regular. The result was as follows: If with the right eye I saw ring n, and with the left eye ring p, with both eyes I saw rings $n + p$, whatever the values of n and p, which varied with the illumination. The deviations from this were always very small and variable. This fact was verified by two other observers. The intensity of luminous sensation is evidently from this experiment greater with two eyes than with one, and it also shows that the increased sensation which gives rise to the perception is the same in the two cases. These experiments thus give considerable support to Fechner's law.

It remains for me to investigate the differential sensitiveness of the eye as a function of the intensity, and to deduce the law connecting the sensation with the excitation. Bouguer, in studying the degree of accuracy of his photometer, and Masson, employing the rotating disc just described, enunciated the following law: The ratio of the smallest perceptible difference to the total intensity is a constant. Helmholtz had already shown, but without any actual measurements, that the differential sensitiveness passed through a maximum. I undertook similar experiments, supplemented by photometric measurements. The source of light was a standard gas lamp, the value of which was frequently checked by means of a modified previously standardised Mascart photometer. The illumination of the disc was then calculated by the law of inverse squares. The gas lamp was nearly equal to one carcel. The results were as follows:—

Distance of the lamp (metres).	Illumination of the disc (carcel-metre).	Ring perceived.	$\frac{\delta I}{I}$
1	1	7	$\frac{1}{173}$
2	$\frac{1}{4}$	6	$\frac{1}{147}$
3	$\frac{1}{9}$	4—5 } Doubtful.	$\frac{1}{94}$
4	$\frac{1}{16}$	3—4 } Doubtful.	$\frac{1}{72}$
5	$\frac{1}{25}$	2—3 } Doubtful.	$\frac{1}{44}$

Putting these results into the shape of a curve (Fig. 2), the values of I being abscissæ and those of $\delta I/I$ ordinates, I get a branch of an hyberbola having the axis of y as asymptote; this is obvious, since when I approaches zero, δI approaches the minimum perceptible difference, which is not nothing. It must be clearly understood that this curve only applies to my eyes, and to the light from a gas lamp. Everyone must plot his own curve for himself, an extremely simple proceeding. The practical outcome of all this is that if we desire to do good photometric work, we must work with an illumination of about 1 carcel-metre, the observer being about 30cm. from the fields under observation.

But this is not the only consequence concerning practical photometry arising from my experiments. Every photometer includes a diffusing surface divided into two fields, each illuminated by one only of the two sources of light to be compared. The *ensemble* of these two fields is observed either monocularly or binocularly, according to the type of photometer, but the condition which it is always sought to realise is a perfect symmetry of the beams in regard to the normal to the diffusing surface.

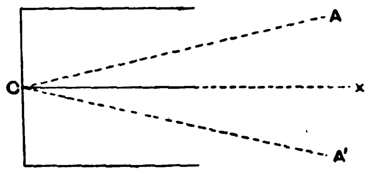

FIG. 3.

The necessity for this symmetry is well known to all who give their attention to photometry. The diffusing surfaces are not perfect, in short, and do not diffuse light equally in all directions. Nothing can be settled about the equal brightness of two fields which are not lighted by beams of the same angle of incidence. An experiment which it is easy to make shows this. Imagine an observer to be agreed as to the equality of the illumination of two illuminated surfaces when he is in a given position. However slightly the observer moves his head, the equality will apparently disappear; from this fact arise most of the errors of photometry. Two measurements are comparable only when they relate to the same position of the eyes as regards the photometer. In my opinion, therefore, every binocular vision photometer at present in use should be fitted with an apparatus intended to keep the observer's head in a fixed position. Such an addition is, moreover, by no means difficult to improvise for ordinary Foucault or Rumford photometers or others on the same principle. It is owing to this defect that binocular vision photometers have almost been abandoned in favour of photometers of the eye-piece type. A similar device is necessary for a photometer on the system pointed out by M. Cornu. I have frequently used a photometer made on this plan (Mascart pattern, large size). I began by having enormous errors, and I found that these errors were diminished when I took every possible care to fix the position of my eye. I then placed a fine wire a little behind the point of observation, and by bringing it always carefully into the same position relative to the separation between the two fields I obtained perfectly concordant results. Finally, in view of the experiments described we should, I think, increase the sensitiveness of the apparatus by adding a double *camera lucida* enabling us to work binocularly and thus to use our visual mechanism in the best conditions. Let us take a Foucault binocular vision photometer, in which the sources of light are movable along two straight lines the bisectrix of which is normal to the diffusing surface (Fig. 3). Let the head of the observer be placed symmetrically

Digitized by Google

with regard to this bisectrix. The arrangement seems symmetrical. So far as apparatus is concerned it is so, physically it is not; for the two eyes of the observer are often very unequal, as I have previously shown, and in accordance with the unequal diffusion in different directions the left eye plays the principal part in the perception of the right field and *vice versâ*. If my explanation is correct, the difference will be greater the greater the angle A C. Experiment verifies this. With an angle of 10° there was an error of 30 per cent., with an angle of 20° about 50 per cent. How is this persistent error to be eliminated? By working with a fixed auxiliary source of light, at A, for instance, and by bringing the two fields to equality, first with the standard and then with the source of light to be measured, both being placed on the line A′C. By placing the standard first along A and then along A′, and the source to be compared first along A′ and then along A, the need for an auxiliary light is obviated.

To sum up, the conditions to be fulfilled by an accurate photometer are as follows:—

(1) It should be adapted for binocular vision.

(2) It should be arranged so that the observer's eyes should always be in a clearly defined position.

(3) It should be arranged to be worked with the sources of light changed over, when a double measurement is impossible.

The first two conditions are easily realised in instruments without eye-pieces. In eye-piece instruments it is only necessary to arrange a fine wire beyond the point of observation, and parallel to the line separating the two fields, and to place beyond the eye-piece a double *camera lucida* permitting binocular vision.

ON THE DEGREE OF INCANDESCENCE OF LAMPS.*

BY A. CROVA.

The determination of the degree of incandescence of lamps can be accurately carried out with a spectro-photometer; but, practically, it can be done sufficiently accurately in the manner proposed by me to the 1889 Congress of Electricians, and recommended by that body.† The luminous intensity in terms of the carcel is determined by interposing a trough containing a mixture of chloride of nickel and perchloride of iron having such proportions‡ that it transmits a certain amount of the radiation comprised between 630*d* and 534, with a well-marked maximum at 582.

A second determination is effected by placing a red glass in front of the eye, the glass being such that it only transmits the radiation comprised between the red end of the spectrum and the vicinity of the D band. The first determination gives the value of the source of light under consideration in carcels; the ratio of the first to the second gives the degree of incandescence. I have shown§ that if we compare two lights of different colour their total intensities are in the same ratio as their intensities measured in the portion of the spectrum of wave-length 582. It is thus both very convenient and very accurate to make photometric measurements with the aid of the 582 trough. When any two sources of light have to be compared they are not, as a matter of fact, usually of identical colour; the 582 solution makes them so, and thus renders the measurement more accurate. The light of a carcel at one metre is too intense, and the interposition of the trough reduces it to such a degree that the smallest difference between the two illuminations on the photometer screen is brought out clearly.‖

As the use of electric lamps and high-power burners is becoming more and more general my method may be employed to discover without much trouble the best working conditions. A few examples will demonstrate the utility of these determinations.

In the case of an arc lamp the degree of incandescence varied from 1·5 to 1·7, the electrical energy consumed being respectively 1,509 and 1,660 watts. For a 16-c.p. glow lamp, this figure varied from 1·05 to 1·23 according as the lamp was more or less overrun. In the case of a Bourbouze lamp with platinum mantle the degree of incandescence was less than unity for small power, but increased with the consumption of gas and compressed air, reaching unity with a proper supply, that being the figure of the carcel.

An investigation of the Auer burner gave some interesting results. The candle-power, degree of incandescence, and gas consumption of the Auer burner tested by me, gave the following figures, which are the mean of a number of determinations:—

Luminous intensities (carcels)*	4·42	5·23	5·35
Degree of incandescence	1·30	1·41	1·47
Gas consumption per hour (litres)*	93	105	102
Consumption per carcel per hour	21	20	19

It will be seen that the candle-power increases with the degree of incandescence, which is in conformity with the principles of radiation by incandescent bodies. If the gas consumption per hour is increased the degree of incandescence, low at the commencement, increases continuously, as also the candle-power, up to a certain limit, beyond which more and more of the gas is uselessly burnt without helping to heat the mantle of refractory earth which forms the wick of this burner. It is, therefore, advantageous to push the Auer burner to that degree of incandescence beyond which it cannot go, whatever may be the gas consumption. Similar tests may be made with various kinds of high-power burners, and accurate data may be obtained as to the best conditions of working.

The case is quite different for gas burnt in an ordinary Bengel burner. In the Auer burner and others of the same kind the quantity of refractory matter is constant, and the maximum effect corresponds to the highest temperature which this matter can attain in a Bunsen flame. In the Bengel burner, on the other hand, a portion of the gas is burnt externally and internally in so far as the cylindrical mass of gas that escapes by the ring of holes is concerned; this consumption of gas causes no deposit of carbon and produces a bluish flame, which is quite negligible from the photometric point of view. The high temperature produced by this non-luminous combustion incandesces the carbon molecules dissociated from the hydrocarbons contained in the mass of gas comprised between the two surfaces of combustion, which surfaces are the true source of light as was shown by the photographic investigation carried out by me.† The quantity of incandescent carbon that emits the light is only a fraction of the total carbon contained in the gas under combustion, and this fraction is all the smaller the lower the flame; if the flame is made small enough all the gas burns blue and there is no useful light. As the gas consumption of the burner increases the relative quantity of dissociated carbon increases; the degree of incandescence diminishes slightly, and the luminous output increases rapidly to a maximum corresponding to the moment at which the flame becomes smoky. A similar result is reached with the Carcel standard, the consumption of which is varied by raising the wick more or less. With a Bengel burner I obtained the following results:—

Luminous intensities.	Gas consumption. Litres per hour.	Gas consumption. Litres per hour per carcel.
0·2	56	280
0·4	78	195
0·6	95	158
0·8	108	135
1·0	120	120
1·2	131‡	109

It follows from these considerations:—

1. That in a hydro-carbon burner by increasing the hourly consumption of combustible the luminous output increases, though the degree of incandescence slightly diminishes, until the output reaches a maximum which should not be exceeded.

2. That in lamps in which the incandesced refractory substance has a fixed value independent of the consumption of combustible, the maximum effect corresponds to the minimum amount of combustible necessary to reach the maximum degree of incandescence.

* 1 carcel = 10 candles (approx.); 1 litre = $\frac{1}{28}$th cubic feet (approx.) litres per hour per carcel ÷ 230 = cubic feet per hour per candle. [Ed. *E.*]

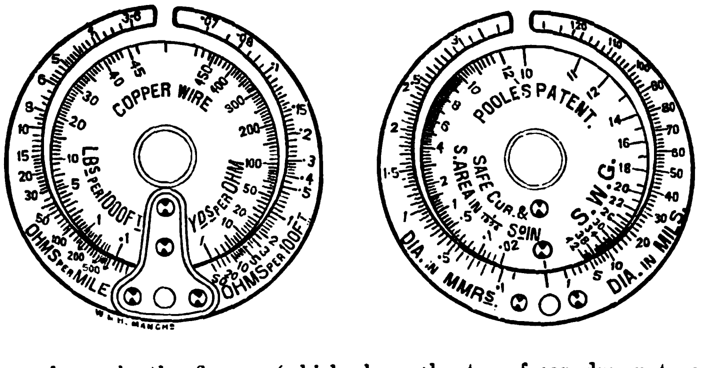
‖ M. Pellin has constructed a slide-bar to my specification, which can be adapted to any photometer, and by means of which these determinations are very easily carried out.

A NEW WIRE GAUGE.

In these days of general and electrical progress in metal working the gauging of wires has become of much importance, and the necessity of some substitute for the clumsy slot gauge hitherto in general use has become obvious. The latter form of gauge simply shows if a wire conforms to some one or other number of a certain gauge such as the standard or Birmingham wire gauge, but gives no other information. Such gauges are seldom, if ever, quite reliable, especially in regard to the smaller sizes. To obtain the actual size of a wire recourse must be made to a micrometer gauge.

Digitized by Google

A wire-gauge has been designed by Mr. Poole, of the New Telephone Company, Manchester, to give in one small handy and compact instrument various information in regard to copper wires, such information being given at a glance without calculation or recourse to vernier scales, which seem to be most puzzling to most people. The wire to be measured is passed through the opening in the outer ring (which itself gauges to No. 10 standard wire gauge)



as shown in the figures (which show the two faces drawn to a scale of two-thirds full size) and drawn along one of the slots until stopped, the sizes being then shown at the points of contact of the wire with the sides of the slot which may be taken as opposite the centre of the wire. The various particulars as detailed on the instrument can thus be found at once.

ELECTRIC LIGHTING OF RAILWAY CARRIAGES.*

According to the experience of the Allgemeine Elektricitäts-Gesellschaft of Berlin, the simplest solution of the problem of the electric illumination of passenger carriages on railways is to be found in accumulators pure and simple. We give in the following lines the main features of a system of train lighting by electricity, as recommended by the Allgemeine Elektricitäs-Gesellschaft, chiefly on the basis of their experience on the Dortmund-Gronau-Enschede line. It is one of the Government railways of Prussia, about 60 miles long, leading from the very busy Dortmund district across the sparsely populated and quiet plains of north-west Westphalia, to the little town of Enschede, in the kingdom of the Netherlands, a few miles beyond the frontier. The plant has been running for more than a year. The cells employed are a special type of the accumulators of the "Accumulatoren-Fabrik Hagen," expressly made for the Berlin Company. A battery capable of feeding five 5-candle lamps for 40 hours would weigh 467lb., if discharged at 15 volts; if 22·5 volts are desired, the weight rises to 516lb.; if 30 volts, 591lb. The capacity should leave a reserve of about 10 per cent. or more. As a rule, discharge at 22 5 volts, requiring 12 cells, will answer best. A battery of this voltage, capable of feeding five 16-candle lamps for 8, 12, or 16 hours, would weigh 443lb., 516lb., and 562lb. respectively. If two lamps are desired for each compartment, two batteries with one lamp in each circuit would prevent a total extinction of the light if the battery should give out. Two 8 or 10-candle lamps replacing one of the 16-candle lamps just spoken of would require batteries weighing 754lb. and 886lb. respectively for 12 and 16 hours' service. The cells are put in cases not too heavy to be managed by one man, and these cases placed under the cars, like the ordinary gas reservoirs. As regards comparative weights, we are assured that the gas plant for five jets for 40 hours, would weigh about 1,000lb., whilst the equivalent electric plant, with a battery of 12 cells, would not weigh more than 640lb. Sometimes the cells are placed under the seats. The connections consist both of contact springs and of flexible cords. The discharged cells are exchanged and recharged in the lighting station. Where this is not feasible, the charging may be done on trucks on some siding, or with the cells in position, in which case the train has for hours to remain on that siding. This latter arrangement has not much to recommend it. A hint given in the pamphlet that the somewhat impoverished cells taken out of a first-class carriage might still do for a third or fourth class compartment, would hardly be welcomed in this country. For the German railways, the company reckon as minimum illumination admissible: one lamp of 16 candles for the first class, one of 10 candles for the second and third classes, and two lamps of 6 candles for the fourth class. That would enable the first-class traveller to read comfortably on any seat, and those in the second and third classes on four of the 10 seats; but two lamps of 8 or 10 candles would be more convenient for the first two classes, and proportionately better light for the other two classes as well. The lamps used on one line should, as much as possible, be of the same kind. The lamps of higher candle-power being more economical as regards current consumption, a good light can be given. Every battery needs a switch; the switches should be accessible to the guard only. It has not been found profitable to allow passengers to turn the light on and off as they like, although a good deal of light might occasionally be saved if the passengers were considerate. The Company do not want the passengers to touch anything but the screens. The state of the battery is indicated by voltmeters or by Aubert's hour-counters. The latter are very simple, but as they only show for how many hours the battery has been discharging, they can be used only with constant and uninterrupted supply. The leads are put under wood or encased in gas-piping; on the engine the wires are lead cables placed in gas pipes. Ample space is left everywhere between the two wires of each circuit. When desired, cistern, boiler, engine, dynamo, and cells are supplied, or a petroleum motor instead of the steam plant. These motors cannot be guaranteed free of smell. On lines where trains run backward and forward without being uncoupled, the whole accumulator plant may well be placed on a special truck. This system is in use on some of the Danish isles and on the west coast of Sweden. About cost, the pamphlet—besides offering estimates—does not say anything beyond stating that the electric lighting of the Dortmund-Enschede line does not cause any higher expense than the illumination by gas would cause, although the plant is neither large nor perfect as regards full utilisation of the machinery. On this line the ordinary officials look after the accumulators.

* From *Engineering*.

A HYDROSTATIC ELECTROMETER.

A new absolute electrometer, due to Signor G. Guglielmo, is described in the current number of the *Zeitschrift für Instrumentenkunde*. It consists essentially of a flat dish filled with a conducting liquid and communicating with a burette. The flat rim of the dish is provided with three insulating feet, upon which rests a metallic disc with a truly plane under surface. When electrified, this disc attracts the liquid and raises its level, and to restore it to its former level it is necessary to withdraw some of the liquid from the burette. The readjustment is controlled by a pointer which is mounted in the flat dish and touches the surface of the liquid from below. The amount of liquid withdrawn is weighed or measured, and this gives the difference of level, and hence the electric pressure. The apparatus is improved by having two flat dishes communicating with each other and with the burette, and by surrounding the second one with a circular tank serving as a "guard ring" and provided with its own burette. Signor Guglielmo recommends aqueous saline solutions or acidulated water as liquids, since mercury is too little sensitive. In another form of the apparatus, the saline solution is contained in a flat dish, and a short piece of wide glass tubing is immersed in it so as not to touch the bottom. A layer of insulating liquid of approximately the same density as water is poured over the glass tube, which is provided with a guard ring, and surmounted with the disc to be electrified. When that is done, the solution rises in the tube and falls outside it, the rise being the greater the less the difference of density between the two liquids.

CORRESPONDENCE.

PROLONGING THE LIFE OF ARC LAMP CARBONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The "curious device due to Herr Francis Jehl," described on page 718 of your current issue, appears to be a mere modification of the Hazeltine "tip," patented in America and in this country a little more than four years ago; and it differs from the latter merely in mechanical details.

Werdermann was, so far as I know, the first to point out the advantages of shielding the hot ends of the carbon rods from contact with the air; and for this purpose he coated his carbons with fire-clay, lime, glass, and other materials. See his British Patent, No. 4,805 of 1876.—Yours, &c.,

Norfolk House, Norfolk-street, Strand, London, W.C., October 23rd. — J. G. LORRAIN.

Digitized by Google

CONTRACTORS *versus* MANUFACTURERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Now that the electrical industry is so rapidly establishing itself in nearly every provincial town, one who has had considerable knowledge of the ups and downs of a contractor's life notes, with mingled feelings of amusement and annoyance, so-called installation branches being opened by all sorts and conditions of electrical engineers and manufacturers; but surely for a firm of cable manufacturers to take up wiring work must ultimately prove a fatal step as regards the interests of the shareholders of any such concern. There are firms whose names it is needless to mention, and there are others whose names would be conspicuous by their absence were I to trouble you with a list. Surely, when one takes into consideration the fact than in an ordinary installation of any size the value of the cables and wires alone is generally about one-third of the total cost, it must be apparent to those who understand the business that it is a most unfair and foolish step for any cable manufacturer to take up to any extent ordinary wiring work. I have a glaring instance brought to my notice of orders during the last 12 months of some thousands of pounds in value having passed by a firm of considerable repute in cable manufacturing solely on the ground of this suicidal policy which they appear to have adopted, and although there are numbers of other manufacturers of electrical apparatus who do installation work, yet at the same time a contractor knows that it is as a rule the cables which make up, as I before stated, about one-third the total cost of the job.

Now, with regard to manufacturers of electrical sundries, who are also in a number of cases contractors, this appears to me to be a decided step in the right direction, as it is on the accessories to a very great extent that the success of electric lighting depends. A manufacturer of electrical sundries who has installation work of his own can design and construct an article which he, from his own personal experience and that of his staff around him, knows to be thoroughly suitable and efficient; and when that article is produced it is to the benefit of the trade that he places it before them. There are a very large number of accessory manufacturers who supply goods, which, when bought by the unwary and installed on some unlucky client's premises, are found to be absolutely unsuitable for the work for which they are intended to be used, and, furthermore, in design are proved to be very faulty. Such goods are not supplied by the manufacturing contractor, and it is, therefore, as I have previously stated, no doubt a step in the right direction to see some of the largest firms busily developing the electrical accessories department. I might mention that the cost of sundries on an average installation amounts only to about one-eighth of the total. Thus it will be seen that the cable manufacturing contractor gets by far the largest chance of profit out of his contractor.—Yours, &c.,

CONSULTING.

Thermocouples with Liquids.—In *Wiedemann's Annalen*, No. 11, Herr August Hagenbach gives his results obtained with thermocouples consisting of a metallic wire whose terminals were inserted into a hot and a cold portion respectively of a saline solution. The combinations employed were zinc with its chloride and sulphate, copper and cadmium with their respective sulphates, and platinum with zinc, cobalt, copper and cadmium sulphates, copper and cadmium chlorides, and chrome alum. Of these combinations the most powerful was that of platinum with a 5·6 per cent. solution of cupric chloride. With one terminal at 20°C. and the other at 80°C., the E.M.F. developed was 0·146 volts, but it was less with either a higher or a lower percentage of the salt. On the whole, the behaviour of salts of the same acids was similar. In the combinations of the metals with their own salts, the E.M.F's developed increase more rapidly than the difference of temperature, the deviation being more marked with the more dilute solutions. Of the two modifications of chrome alum the green variety shows a decided superiority to the voilet variety.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The 1894 Edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK contains 1,000 closely-printed pages, and several new and useful features have been added. The price of this edition of the Directory and Handbook is now 5s. post free; abroad 5s. 6d. *The 1895 edition is in active preparation.*

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell, with this title, will be ready in a few days. It will contain the latest information respecting the application of electric energy to mining purposes, in which the author has hac much experience. The book is well printed, on good paper, and will contain nearly 250 illustrations, a large proportion of which have been specially made for the book. The price is 10s. 6d., post free 11s. (abroad 11s. 6d.). Orders can now be sent in.

"THE WORK OF HERTZ."—The lecture delivered by Dr. O. J. Lodge at the Royal Institution on June 1st is reprinted with corrections and additions, and many original illustrations, price 2s. 6d. net.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"ELECTROMAGNETIC THEORY," by Oliver Heaviside, is now ready, price 12s. 6d. (abroad 13s.). Prospectus on application.

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—This book, written by Mr. F. Marten Weymouth, is also ready; price 7s. 6d (abroad 8s.). Prospectus on application.

TENDERS INVITED.—The Corporation of Sunderland invite tenders for wiring the Town Hall for the electric light, including the supply and fixing of cables, casings, switch and fuse boards, lamps, &c. Specifications, schedules, and general conditions may be obtained from the borough electrical engineer, and tenders must be delivered not later than 5 p.m. on Thursday, November 8th. Further particulars appear in our advertisement columns.

——— The Postmaster-General invites tenders for the supply of red fir telegraph poles, and for creosoting the same. Forms of tender, containing all particulars, can be had on application to Mr. Charles E. Stuart, Controller of Stores, Telegraph-street, London, E.C. Tenders have to be in by noon on Wednesday, the 31st inst.

TENDERS ACCEPTED.—The tender of Messrs. Willans and Robinson (Limited) has been accepted for two additional dynamos required for the electric lighting station at Whitehaven, the amount being £1,479.

——— The following were the tenders recently received by the Cardiff Corporation for wiring the Town Hall and Market Hall. As announced in our issue of September 28th, Messrs. Fergusson and Co. were the successful tenderers:—

	Town Hall.			Market.		
Knapman, Hodder and Co.	£994	18	6	£740	7	6
Sidney F. Walker and Co.	705	0	0	610	0	0
J. B. Saunders and Co.	678	0	0	483	0	0
W. and T. Robinson (Limited)	636	10	0	480	17	0
F. W. Ball and Co.	553	5	7	507	18	9
Fowler, Lancaster and Co. (Limited)	493	15	0	232	10	0
Clay Bros. and Co.	318	0	0	245	0	0
Maunsell, Mercier and Co.	264	0	0	198	0	0
Fergusson and Co. (accepted)	338	0	0	185	0	0

——— At Tuesday's meeting of the London County Council a report was received from the Main Drainage Committee that the Naval Construction and Armaments Company (Limited), the builders of the new sludge vessel, had asked to be allowed to sublet the installation of electric light on the vessel to Messrs. Paterson and Cooper. The Committee saw no objection to this, and accordingly recommended that the Naval Construction and Armaments Company (Limited) be allowed to sublet to Messrs. Paterson and Cooper the installation of the electric light on the new new sludge vessel, and that the conditions of the Council's standing orders with respect to sub-contractors be in this instance dispensed with. The recommendation was approved by the Council.

APPOINTMENT VACANT.—An advertiser invites applications for the post of assistant electrical engineer for a low-tension central station. The post is in connection with a municipal electric light supply station.

Digitized by Google

APPOINTMENT.—The Town Council of Taunton have appointed Dr. J. A. Fleming consulting electrical engineer for the year ending September 1, 1895, at a fee of 25 guineas, with a fee of 10 guineas per visit to Taunton and travelling expenses.

———— Mr. Charles Turner, A.M.I.E.E., who is acting as resident engineer in charge of the work for the lighting of the parishes of St. Luke's and Clerkenwell, commences his duties under the Salford Corporation next week, at a salary of £250 per annum. Mr. Turner was previously with the Woking Electric Supply Company.

FORTHCOMING SALES BY AUCTION.—Messrs. Fuller, Horsey, Sons and Cassell announce in our advertisement columns that the modern electric lighting plant which has been previously offered for sale as a whole is now to be disposed of in lots under the hammer. The plant is quite as good as new, having only been used for a short period, and is only now to be disposed of because the owners require the space, and are taking current from the City of London Company's mains. The plant comprises 2 loco-type boilers, 3 Armington-Sims engines, 3 Elwell-Parker dynamos, 52 E.P.S. cells, and a number of measuring instruments, switchboard, and other apparatus. The sale takes place on Wednesday, November 28th, at one o'clock. Orders to view the plant at Billiter-buildings, Billiter-street, E.C., together with catalogues, may be obtained of the auctioneers, 11, Billiter-square, E.C., or of Mr. H. Cuthbert Hall, 46, Queen Victoria-street, London.

———— Messrs. Wheatley Kirk, Price and Goulty announce the sale by auction of an extensive assortment of machine tools, engineers' plant, loose tools, stores, &c., at the Union Foundry, Leeds. The auctioneers especially call the attention of machinery buyers to this important sale. Messrs. Shepherd, Hill and Co., the proprietors of Union Foundry, have earned a world-wide reputation for excellency in workmanship and design of their machine tools. The same firm of auctioneers hold a sale at Ditchingham, Norfolk, of silk-weaving, &c., plant, formerly in use by the celebrated old Norwich firm of Grout and Co. This sale takes place on Thursday next. The above sales by Messrs. Wheatley Kirk, Price and Goulty are in addition to the sale of engines, dynamos, cable, copper tubing, &c., which is to be disposed of at the Deptford Central Lighting Station, London, S.E., and of which a preliminary announcement appears in our advertisement pages.

RECENT SALES.—Messrs. Wheatley Kirk, Price and Goulty last week disposed of engineering plant, tools, &c., at Messrs. W. H. Allen and Co.'s York-street Works, Lambeth. A good company of buyers assembled from the provinces, and prices for machine tools ruled fairly high, some lots securing considerable competition.

BANKRUPTCY.—Under a receiving order granted against William David Gooch, electrical engineer, accounts have been furnished showing liabilities £4,365, with assets of uncertain value. The debtor states that for many years he was engaged as consulting engineer and otherwise to various undertakings at home and abroad. From about 1885 to 1888 he carried on business on his own account at 2, Victoria-mansions, Westminster, during which time the bulk of his present indebtedness was incurred in connection with speculative electrical contracts, &c. For about 12 months he was a partner in the firm of Lidstone and Co., of 2, Victoria-mansions, Westminster, engineers and patentees, but the partnership was dissolved in 1888. Since then he has had occasional engagements as consulting and electrical engineer, and for the last five months has been in the employ of an electric welding company, his fees or salary therefrom averaging about £6 per week. The debtor attributes his insolvency to losses in 1885-88 in connection with speculative electrical contracts and industrial patents in which he was interested, and partly to law costs, including, particularly, the liability to the petitioning creditors. The Official Receiver (Mr. H. Brougham) states that the debtor makes no proposal and has been adjudged bankrupt.

———— The first meeting of creditors of W. H. Akester, whose bankruptcy we noted last week, is to be held at the Bankruptcy Court, Carey-street, W.C., on November 2nd, at 11, and the public examination will be held at the same place on November 21st, at 11.

———— The discharge of F. Silvester, who traded as F. Silvester and Co., ironfounders, of Newcastle-under-Lyme, and who became a bankrupt last year, has been suspended for two years.

———— Under the failure of Messrs. Young and Buss, trading as wholesale ironmongers at Blandford-street, Baker-street, accounts have been furnished showing total liabilities £13,180, of which £7,249 is unsecured, and assets £4,483. The business is stated to have been founded fifty years ago by Mr. John Young, sen., who retired from the firm in the year 1882. Mr. H. W. Figg is trustee of the estate, with a committee of inspection.

———— At the Halifax Bankruptcy Court on Tuesday a receiving order was made in the affairs of Frederick Leopold Wovilliard-Rigg and Harry Ernest Scarborough, trading as Messrs. Wovilliard, Scarborough and Co., electrical and mechanical engineers, Wade-street, Halifax. The liabilities are stated to be about £500, and the assets £300.

LIQUIDATIONS.—A petition has been presented by the Bedford Engineering Company (Limited) for the winding up of J. G. Statter and Co. (Limited), and is down for hearing at the Royal Courts of Justice, Strand, W.C., on October 31st.

———— Mr. G. Sneath has presented a petition for the winding up of Dalziel's News Agency of America (Limited), which is set for hearing at the Royal Courts of Justice, Strand, W.C., on October 31st.

———— In the list of creditors of Barnard, Bishop and Barnards (Limited), Norwich, now being wound up, five German firms figure for a total of close upon £4,300, the remaining 40 British creditors claiming between them a total of £2,450.

RECEIVER APPOINTED.—Mr. Justice Stirling on Wednesday heard a motion asking, on behalf of the holders of a series of debentures, for the appointment of a receiver and manager of the British Electric Light Company (Limited). Counsel stated that under the terms of the debentures, if the principal money was not paid on July 31, 1894, the whole of the Company's undertaking and property should become specifically fixed and charged therefor, and that principal and interest should forthwith become payable. Payment of the principal had been demanded and had not been made, and the interest had been in arrear for a year. The Company did not appear, and his Lordship said there would be the usual order.

AGENCY.—Mr. G. Straus, of Queen Victoria-street, London, has been appointed sole agent for Great Britain and the Colonies of L. Barrière, of Paris, for metal screws, terminals, metal turning, &c.

BUSINESS CHANGES.—Owing to ill health, Mr. W. E. Hayne has been compelled to retire from practical work, and has disposed of his Brighton business to Mr. T. King, of Maidstone, who has appointed Mr. C. Rawlings as manager. Mr. Hayne has commenced practice as a consulting engineer at Ebor House, Bexhill-on-Sea.

DISSOLUTIONS OF PARTNERSHIP.—Messrs. Percy and Walter Andreae, carrying on business as electrical engineers at 85, London-wall, E.C., and at 179, Victoria-street, Westminster, S.W., and elsewhere, have dissolved partnership.

———— Mr. E. Smith has retired from the firm of the Electric Shot Firing Company, and the business will in future be carried on by the remaining partners, Messrs. T., W. A., and S. R. Malson.

REPORT.—Messrs. B. Verity and Sons request us to state that they are exceedingly busy, and have been obliged to put down additional machinery in order to cope with the pressure of orders.

THE "MELDRUM" FORCED DRAUGHT.—We hear that the Lancashire boilers for the new Bolton electric supply station are being fitted with the "Meldrum" forced draught apparatus. This system of steam-blast draught has been tried and found successful at several electric supply stations in London and elsewhere; and it has, we believe, proved a valuable feature in the boiler plant at times when it has been necessary to get steam up quickly, or to steam harder than the usual rate. Another feature of the "Meldrum" system is the readiness with which it can be adapted to the combustion of dust fuel and dry refuse, which it is difficult or impossible to burn in an ordinary furnace with natural draught. The ready control which can be exercised by the stokers over the draught, with the "Meldrum" apparatus, is of great service in regulating the variations in the productions of steam, especially where the load on the boilers is liable to sudden and frequent change.

RAMSAY'S ANTI-GROOVING GEAR FOR COMMUTATORS.—Several more or less successful attempts have been made at various times to devise a mounting for the dynamo brush-holder which will obviate the grooving due to the brushes on the commutators. The latest idea is that of Mr. Alex. Ramsay, who proposes to mount the brush-holders and rocker on a sleeve placed on an extension of the dynamo spindle, the sleeve having a screw thread cut on it to enable the position of the brush-holders to be varied longitudinally. When not required to shift along the screw sleeve, the rocker is held in a fixed position by a set screw which locks the rocker in any desired position. We believe the arrangement has quite recently been patented by Mr. Ramsay.

AUTOMATIC RECORDING INSTRUMENTS.—Mr. L. Casella writes to inform us that he has been appointed agent in Great Britain, the Colonies, and America, for Richard Frères' automatic recording instruments, concerning which an illustrated and descriptive catalogue is now ready.

ARC LAMP COMPETITION.—We have received the following communication from Messrs. Crompton and Co. (Limited):—"In these days, when the question of improved arc lighting is now so promi-

Digitized by Google

nently before the public, it may interest your readers to know that we have been successful, with our new simplified Crompton-Pochin type of lamp, in obtaining the order for the street lighting of Edinburgh. Although a large number of makes of lamps were tendered for, only three were selected for trial, and of these our lamp was judged best suited for the purposes of the Corporation. The conditions of the competition were not limited to the comparative excellences of the lamps; but the question of the economical use of carbons was also taken into consideration. We believe this is the first time that a tender has been so carefully adjudicated on, so that the results in this case are especially gratifying to ourselves."

Plume Shades.—Messrs. Charles Ingle and Co. have now ready a price list of selections of plume shades designed by Miss Beatrice Devonport, samples of which were recently illustrated and described in *The Electrician.* It is difficult for ordinary wood or process block illustrations to do justice to these artistic arrangements of feathers, and we fear the illustrations given in the list are not calculated to attract notice, but so many elegant designs are possible with the material used that the shades will doubtless continue to have a large sale. They are supplied in a number of tints and colours, and combinations can be repeated for subsequent orders.

Screws and Terminals.—The Automatic Standard Screw Company, Halifax, send us a copy of their general stock list of screws, pins, terminals, &c., specially prepared for telegraph, electrical, and optical work, for which the Company have received several special awards. The Company keep large stocks of taps and dies, including the Whitworth, B.A., the Sellers', the common V thread, and others, and are prepared to execute orders for any pitch or diameter of screws. The list can be obtained by the trade on application.

Adelaide (South Australia).—The Corporation have been considering the question of the electric lighting of the city, and, it being understood that they were proposing to spend some £50,000 in laying down a central station plant, a deputation of citizens waited upon the Town Council on August 6th to lay before them reasons why this expenditure should not be proceeded with. It was urged that as the Gas Company had offered to reduce the price of gas, it was not advisable to incur such an outlay of capital for a possible saving of a few hundred pounds a year. The deputation were informed that the Electric Lighting Committee would reconsider the whole question. It is understood that the South Australian Hydraulic Power Company have submitted to the Committee a proposal to light the streets of the city by the electric current, giving a total light equal to 250,000 candle-power, against the 12,577 now derived for the public gas lamps, at the price now paid for gas, for a term of 21 years; the Corporation to have the option of purchasing the undertaking at the expiration of that time. The Company would also pay the Corporation a percentage on the net profit derived from private lighting. The Company say that they would be able to supply electrical energy at a cheap rate, and they could have their plant ready by the time of the expiry of the present gas contract.

Birmingham.—On Tuesday the Market Hall was lighted by electricity for the first time, the ceremony of switching on the current being performed by Mr. Councillor Parkes. The installation consists of 42 arc lamps with a total of about 50,000 candle-power, and the light is well distributed over the hall. The current is taken from the mains of the Birmingham Electric Supply Company, and will cost £507, and £25 for carbons per annum, against £522 previously paid for gas-lighting, the quality of which had been matter for complaint for some time.

Bootle.—The Town Council have resolved to apply for a Provisional Order.

Cartmel (Lancs.).—A public meeting was held at Cartmel last week to consider the advisability of laying an electric railway through the Cartmel Valley. Mr. John Hesketh, of Blackpool, was amongst the speakers, and it was pointed out that the railway would be of great service to the farmers and the inhabitants generally, and that the large waterfalls in the district could be utilised very cheaply and effectively for driving the dynamos, the current from which would also be available for electric lighting. The meeting, which was favourable to the ideas, was ultimately adjourned *sine die*, and in the meantime Mr. Ramsbotham, the convener, will endeavour to formulate a scheme for the carrying-out of the undertaking.

Chapel Lighting.—The first public building in Cheltenham to be wired for the supply of the electric current from the Corporation mains is Salem Chapel, the installation in which will be equivalent to 270 8-c.p. lamps.

Coventry.—The Town Council have decided upon 6d. per unit as the charge for the electric current.

City of London.—The Commissioners of Sewers have referred to the Streets Committee the question of the advisability of including Finsbury-circus among the main streets for electric lighting purposes.

Ealing.—The Surveyor reported at the meeting of the Local Board last week that application had already been made for 2,500 private lamps, half the number estimated for.

Hanley.—At the meeting of the Town Council, on Tuesday, it was reported by the Electric Lighting Sub-Committee that the applications for the electric current from private consumers had been so numerous that, if the markets were electrically lighted, all the available energy would be taken up. They therefore recommended the tenders for an additional engine and alternator to be obtained, and that the electrical engineer be requested to submit at an early meeting a scheme for the extension of the plant and mains for supplying the electrical energy likely to be required within the area of supply, that part of the scheme relating to the compulsory area being submitted for first consideration. The sub-committee also recommended that the town-clerk be requested to write to the Brush Electrical Engineering Company, requiring them to forthwith put the electric lighting plant and machinery into proper working order to the satisfaction of the borough surveyor in accordance with the terms of their contract. In moving the confirmation of these minutes, Alderman Shirley said the extent to which electrical energy had been applied for was simply phenomenal. All the power they were at present able to supply had been asked for, and the committee were, therefore, compelled to take steps with a view of providing additional plant and increased energy. The Board of Trade required them to retain surplus energy to the extent of 20 per cent., so that it was compulsory for them to provide extra power if they wished to meet the demands upon them. Mr. A. Wood, in seconding the motion, said it would have been better if the committee had got the existing plant out of the hands of the contractors before taking steps to provide additional plant; but, seeing that they had not sufficient power to light their markets now the wiring was complete, the committee thought it desirable to proceed with obtaining further machinery without delay. The motion was then agreed to.

Hillgrove (New South Wales).—An electric plant has been supplied to this town by the Crompton Electric Supply Company of Australia. The dynamos are driven by turbines, the water-power of the Gara Falls, situated about six miles away, being utilised. At present current is only to be supplied for the electric lighting of the public streets; but the Company hopes shortly to be in a position to supply it for both private lighting and power purposes. It is expected, when the latter is available, that the low-grade mines in the district may be worked profitably.

Islington (London, N.).—The work in connection with the laying of the mains for the electric light was commenced on Wednesday.

Leeds.—The temporary electric lighting of the grounds and picture gallery at Temple Newsam during the recent visit of the Duke and Duchess of York was placed in the hands of Messrs. Maunsell Mercier and Co., of Manchester.

Liverpool.—The City Council are to be asked at their meeting to-day to open up negotiations with the Liverpool Electric Supply Company (Limited) for the purchase of their undertaking.

Loans to Young Tradesmen.—There is a City of London charity known as Wilson's Loan Charity, which grants to young tradesmen under the age of forty years carrying on business in the City of London, or within five miles, and who have been in business one and not more than three years, and have succeeded to an extent to justify it, the loan at 2 per cent. interest per annum of from £100 to £300 for a period of five years. Three unquestionable sureties are required for £100, and four for larger amounts. Personal application has to be made to the Clerk of the Trust, Chamber of London, Guildhall, E.C.

Luton.—The Highways and Lighting Committee having reported favourably to the last meeting of the Town Council on the proposal to apply for a Provisional Order, a special meeting of the Council is to be held to decide the question.

Madras.—The Government has sanctioned an estimate of Rs.17,230 for lighting the Arkonam railway station and yard by the electric current.

Mill Lighting.—The Seebpore and Howrah mills, Calcutta, are to be electrically lighted. The installation in each case will consist of 1,300 8-c.p. incandescents, current being generated by three E.C.C. dynamos, each coupled direct with a steam engine. The tweed factories of Messrs. Gibson and Longair, Selkirk, and of Messrs. Dalziel, of Walkerburn, are also being fitted up for the electric light.

Monmouth.—The Town Council in committee have reduced the number of proposed sites for the works required for the combined drainage and electric lighting scheme to two—the Osbaston farm

Digitized by Google

and Brooksholme. The engineers state that they will be able to complete the works in about a year from the time of commencement, which will be undertaken immediately the sanction of the Local Government Board has been obtained.

PADDINGTON (LONDON, W.)—The Guardians have decided to light their infirmary by electricity.

ST. LUKE'S (LONDON, E.C.).—The work of laying the mains for the parish electric light supply was commenced on Wednesday.

TECHNOLOGICAL EXAMINATIONS.—The following list of prize-winners is extracted from the Report of the Examinations Department of the City and Guilds of London Institute, just issued :—

Electric Light and Power Distri ution.

Eborall, Alfred Cecil, 3rd Ordinary, £1 (Goldsmiths) and Bronze Medal, Finsbury College, London.
Ferris, Thomas Howard, 1st Honours (Sec. II.), £3 (Goldsmith's) and Silver Medal, Merchant Venturers' Technical College, Bristol.
Hawkins, Walter, 1st H. (Sec. III.), £3 (Goldsmiths) and S. M., Finsbury College, London.
Lewis, Philip Marpole, 2nd H. (Sec. I.), £3 (Goldsmiths) and B. M., Finsbury College, London.
Pinkerton, Andrew, 2nd H. (Sec. II.), £3 (Goldsmiths) and B. M., City and Guilds Institute, Examinations Department, London.
Sheardown, Percy S., 2nd O., £2 (Goldsmiths) and B. M., Finsbury College, London.
Shepherd, George M., 1st O., £2 (Goldsmiths) and S. M., Goldsmith's Institute, London.
Weymouth, George Andrew Philip. 2nd H. (Sec. III.), £3 (Goldsmiths) and B. M., Municipal Technical College, Derby.

Electro-Metallurgy.

Freeman, Frederick James, 1st O., £2 (Armourers and Brasiers) and S. M., Municipal Technical School, Birmingham.
Harris, Edward Victor, 3rd O., B. M., Municipal Technical School, Birmingham.
Weightman, Alfred Thomas, 1st H., £3 (Armourers and Brasiers) and S. M., City and Guilds Institute, Examinations Department, London.
Wilson, John H., 2nd O., £2 (Armourers and Brasiers) and B. M., Municipal Technical School, Manchester.

Mechanical Engineering.

Amor, Edward Robert, 4th O., £1 (Skinners) and B. M., Technical Schools, Devonport.
Berry, Frederick, 3rd H., £2 (Skinners) and B. M., Municipal Technical School, Manchester.
Cairns, Charlie Waldie, 2nd O., £2 (Skinners) and B. M., School of Science and Art, Newcastle-on-Tyne.
Honiball, Charles Roland, 2nd H., £3 (Skinners) and B. M., School of Science, Liverpool.
Jopling, Frederick William, 3rd O., £1 10s. (Skinners) and B. M., School of Science and Art, Newcastle-on-Tyne.
Parker, John, 5th O., 10s. (Skinners) and B. M., Woolwich Polytechnic, London.
Tod, James Niebuhr, 1ft O., £2 (Skinners) and S. M., Heriot-Watt College, Edinburgh.

Telegraphy.

Booth, Augustus C., 1st H., £3 (Pewterers) and S. M., Telegraphists' School of Science, G.P.O., London.
Frazer, William Ross, 2nd H., £3 (Pewterers) and B. M., Technical and Art School, Inverness.

Telegraphy and Telephony.

Eborall, Alfred Cecil, 1st O., £2 (Pewterers) and S. M., Finsbury College, London.
Mackenzie, John Donald, 2nd O., £2 (Pewterers) and B. M., Glasgow and West of Scotland Technical College, Glasgow.
Smith, David, 3rd O., £1 (Pewterers) and B. M., Robert Gordon's College, Aberdeen.

Telephony.

Frazer, James, 1st H. £3 (Pewterer's Company), and S. M., Robert Gordon's College, Aberdeen.
Whillis, Charles, 2nd H., £3 (Pewterers) and B. M., Telegraph School, Newcastle-on-Tyne.

Typography.

Jones, William Charles, 1st O., £2 (Cordwainers) and S. M. (*Electrician* Office Apprentice, 5th year), Borough-road Polytechnic, London.

THE RATING OF ELECTRIC LIGHTING COMPANIES.—The Birmingham Electric Supply Company (Limited) on Monday appealed at the Birmingham Quarter Sessions against a poor-rate assessed on March 30th last by the Churchwardens and Overseers of the poor for the parish of Birmingham. Counsel for the Company said that it was first rated in 1892 at £825 gross and £700 net. In 1893 a simple principle of doubling was applied, and the gross was raised to £1,650 and the net to £1,400. In the present year the overseers had not doubled the amount; but they suggested adding 50 per cent. on, and raising the gross to £2,475, and the net to £2,100. The case was a very important one to the Company. Up to the present no effort had been made to rate an electric company on a really scientific basis, and it was obvious in this case that the overseers of Birmingham had not rated upon any ordinary principle which should apply generally to the rating of companies. They had applied a rough and ready principle of taking 15 per cent. off the gross to arrive at the net, but this was not a principle which should apply to this Company, which was more like gas or railway companies than anything else. It was maintained that the total rateable figure, on the most liberal way of regarding it from the Overseers' point of view, amounted to a sum of £1,400. Expert evidence was then given. Counsel having addressed the Recorder on behalf of the Overseers, submitting that the assessment made by them was perfectly justifiable, the Recorder before adjourning the hearing of the case, said that he had formed opinions, to which, however, he did not bind himself, and which were subject to what was to be said on both sides. He had come to no conclusion in regard to the accumulators which had formed one of the principal points of dispute. Of the other disputed items he should strike out the tenants' income-tax, and also the contracting account. He did not think he could allow anything for the compulsory termination of concession. Of course these decisions were not final.——On Tuesday morning it was announced that the Overseers and the Company had come to terms, and the appeal was withdrawn. The terms of settlement were not made public.

WALTHAMSTOW (ESSEX).—The Local Board have decided to apply for a P rovisional Order.

WHITEHAVEN.—Mr. Rienzi Walton held an inquiry at the Town Hall, on behalf of the Local Government Board, in reference to an application by the Whitehaven trustees for sanction to borrow an additional sum of £6,304 for electric lighting works. Mr. Brodie, the surveyor and engineer to the trustees, made a detailed statement supporting the application, and there was no opposition.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

October 12, 1894.

19,423. J. H. DUNN. London. Improvements in the construction of retorts or furnaces for the production of gases by the use of electricity.

19,443. P. T. LETCHFORD. London. Improvements in the electrical production of musical notes.

19,444. G. G. STOUT. London. Improvements in electric arc lamps.

October 13, 1894.

19,481. J. W. EWART. London. An apparatus for heating water by electricity.

19,508. C. P. C. CUMMINS and J. L. GOLDING. London. Improvements in cut-outs for use in electric circuits.

19,517. R. WENDER. London. An improved apparatus for indicating the lamp-hours of electric lamps.*

October 15, 1894.

19,560. F. H. ROYCE. Manchester. Improvements in the means of transmitting power of gas engines, steam engines, and the like, for driving dynamos and other apparatus.

19,585. P. A. MOUGIN. London. Improvements in electric arc lamps.

October 16, 1894.

19,603. C. L. CLARKE and W. P. THEERMANN. Manchester. Improvements in ceiling roses, cut-outs, and such like, for electrical purposes.

19,605. B. ANDREWS. London. Improvements in electrical conductors and joints therefor.

19,668. A. F. B. GOMESS. London. Improvements in carbons or electrodes used in arc lamps for electric lighting.

19,681. W. MILLER. London. Improvements in coin-freed telephonic apparatus.

19,702. G. E. HEYL. London. Improvements in accumulators.

19,710. J. A. TIMMIS. London. Improvements in dynamo-electric machines and motors.

October 17, 1894.

19,733. W. HEARN and C. R. GATEHOUSE. London. An electric clock.

19,742. W. P. THEERMAN. Manchester. Improvements in electrical switches.*

19,764. J. HOPKINSON. London. Charging electric accumulators.

October 18, 1894.

19,807. H. OPPENHEIMER. London. Improvements in and connected with electric door contact.

19,842. L. H. CLINE. Wallsend-on-Tyne. Improved electric storage fuse distribution box, also relating to single and double-pole fuses or cut-outs.

23,308. Hutin and Leblanc. Continuous current dynamos.

1894.

4,849. Day and Allmark. Supporting and protecting electrical conductors.
9,974. Thompson (Coffin). Heating metals electrically.
14,634. Buell. Galvanic battery.
16,400. Newton and others. Generating and applying electricity to the body.

COMPANIES' MEETINGS AND REPORTS.

Brazilian Submarine Telegraph Company (Limited).

The forty-second ordinary general meeting of the shareholders of this Company was held on Wednesday, at Winchester House, under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. Richard Collett) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: The receipts for the half-year ended June 30, 1894, were £94,679; for the previous half-year they were £96,262, showing a small decrease of £1,583. The receipts from messages show a decrease of £1,393, and those from miscellaneous receipts, from interest, rents, and transfer fees, show a decrease of £190, resulting in a net decrease, as before stated, of £1,583. The decrease in the interest results, of course, from the fact that the rates allowed by the banks on deposit accounts have during this year been so very low. That we can all understand. With respect to the small decrease in message receipts, I may say that, having regard to the further fall in the value of the Brazilian currency, the loss would have been larger but for the fact that we carried some 40,000 words more than in the previous half-year. This shows a satisfactory growth of traffic with South America, and that notwithstanding there are competing lines which succeed more or less in obtaining part of the traffic, yet the work performed by the Company continues to grow. The sending of news telegrams for publication in the daily Press is increasing, and the companies interested are desirous of affording the necessary facilities whereby this traffic may be fostered. The messages are in plain language, and although carried at low rates, deserve special attention and encouragement. As compared with the corresponding half-year in 1893, the income from messages shows a decrease of £12,181; but this is fully accounted for when we consider the different values of the Brazilian currency collected in the respective half-years. In the June half of 1893 the average rate per milreis was 12½d., and in the half year under review 9½d. While speaking of exchange I may as well treat it up to date. During the current half-year the rate has reached 12½d. and is now 11½d. This welcome improvement is due, I believe, to the much more settled state of political affairs in Brazil and to the blessing of a splendid coffee crop. We must hope the improvement will continue; if it does our business and that of other companies who have, like ourselves, embarked large sums of capital in Brazil will benefit thereby. Leaving the credit side of the revenue account and taking the expenditure, we find that the total for the June half-year was £20,269, and for the previous one £24,284, being a decrease of £4,015. This decrease is practically due to our having been fortunately free from any interruptions of our cables and the consequent expense of repairs. Our freedom from interruption, I am pleased to say, has continued to the present time. Analysing the items of expenditure, I find that the general expenses of the London offices were £2,998 for the period under review, as compared with £2,761 for the previous half-year, or an increase of £237, of which £103 appears under the head of salaries, owing to a re-arrangement of salaries, which I explained fully at a previous meeting; £90 is for travelling expenses to the Continent, incurred in protecting the interests of the Company; £50 in office and general expenses, and £99 for advertising and maps for our customers. On the other hand, there is a decrease of £112 in respect of furniture and office fittings, the expenditure on this head in the six months to December, 1893, being of quite an exceptional character. The working expenses at stations are practically alike, being £13,026 for the last half-year and £13,064 for the previous one. This shows a decrease of £38. This small sum is the difference between a number of increases and a number of decreases in the various heads which appear as working expenses at stations. I can give them in detail if the shareholders wish it; but I think I have given you as much detail as will interest you. In the remaining items of expenditure there are decreases under the following heads: Special legal expenses, £148; staff assurance, superannuation, and pension funds, £87; extensions at St. Vincent, £730; repair of cables, £4,950, and increases in the following: Insurance for spare cable, £13; legal, actuarial, and other expenses of instituting the pension and superannuation funds, £230 (this is an exceptional expenditure, and will not occur again); and expenses of special mission to Brazil (£1,458, to this matter I shall refer again a little later on). That, I think covers the items in the revenue account, the final comparison, being that the result of the working for the June half-year is £2,432 better than that of the previous one, that sum being the difference between the decrease in the expenditure, £4,015, and the decrease in the income, £1,583. An interim dividend at the usual rate of 1½ per cent. has been paid in respect of the March quarter, and £42,501 remains to be dealt with. Of this the Directors have transferred £15,000 to the reserve fund, and now recommend the declaration of a final dividend of 3s. per share, together with a bonus of 1s. per share, making a total dividend of 6½ per cent. for the year. This distribution is the same as that made for the last two years. The balance then remaining to the revenue account, £1,501, is carried forward. Now, gentlemen, I think that is a very satisfactory statement to put before you. Every department of trade, every interest connected with foreign countries, has been more or less suffering. We, however, continue to pay you to-day what we have been paying you, and I think we have to congratulate ourselves that we are able to make such a statement as this. The reserve fund amounts to £692,269. The contributions from revenue account during the last 18 months have only amounted to £42,000, but with the interest on investments the fund stands at a satisfactory figure; but a large and growing reserve is absolutely necessary. There are two cables to be maintained and, sooner or later, renewed; and repairs are likely to come heavier as cables age. One is over 20 years old, and the other 10. Having built up a good reserve, the Directors are enabled to declare the usual dividend and bonus, although the profits are much less than those of a few years back. Gentlemen, I have to throw a little cold water on the statement put before you; but in making my remarks as to our smaller income now, my object is to show you that, notwithstanding this small decrease, we are maintaining our dividend as well as increasing our reserve fund, if not as largely as I should desire to do. Having regard to the wear and tear of the shore ends at the various places where our cables land, and to be prepared with sufficient cable for the repairs and renewals which must be undertaken from time to time, your Directors have had 90 miles of cable manufactured during the half-year, costing about £16,000. The Pacific and European Telegraph Company, as you know, is one of our "feeders" now, and I am glad to say that it is working thoroughly well. The traffic is growing, and I think that it will continue to do so in view of the fact that we are giving a very excellent service. We are not disposed to boast unduly. We think that "slow and sure" is the better policy, but I think you will be satisfied when I tell you that since we have established the line we have already doubled the traffic, and I trust it will continue to grow in the same proportion in the future. You are also aware that we have got £40,613 in the balance-sheet as paid on account of 5,556 shares of £10 each in the Azores Company. I am not yet in a position to make definite remarks on this matter, but I am in a position to say that the Eastern Company have secured a concession from the German Government which will not only give us special advantages in obtaining and carrying the German traffic to and from America, but also over what I call our Eastern system as well; and the Eastern Company not only have this for 40 years, but they have accompanying it—which is always a very satisfactory thing in the beginning of a company—a subsidy from the German Government. By-and-by you will hear something more of this; but meantime I am very pleased to say that the Eastern Company have got this subsidy. They have got the control, it is in friendly hands, and will be used in a just and fair spirit. You will have observed that the statements which I have put before you have been very carefully prepared. We want you to know all that we think you are entitled to know, because the more confidence that can exist between the shareholders and the Directors, the more prosperous and more successful the concern will be. That is our policy; it has been my policy in connection with submarine telegraphy ever since I have had anything to do with it. I have found it successful, and I am too old to change now. I mentioned last time that we were sending out a commissioner or agent to Brazil. We sent out a gentleman to come to an understanding with the Brazilian Government with respect to our cable, the concession in connection with which was for twenty years and was about to expire. They thought it had expired, but we think differently. As, however, I have to be very careful in every word I utter at the present time, I have put my words and thoughts on paper, so that you will know precisely the opinions we have formed, and will be able to judge how far they are correct or not. At our last meeting I told you that the exclusive privilege under our concession granted by the Brazilian Government would shortly expire, and that it was our intention to send out an agent with a view to obtaining from the Government satisfactory arrangements for the future. Under the concession the Brazilian Government undertook not to concede the establishment of another cable between Brazil and Europe or Brazil and Portuguese possessions for 20 years; and the cables and landlines and their working were not subject to any contri-

Digitized by Google

bution or special tax. The Brazilian Government declare the privileges under the concession expired in August, 1892, and from January 1st last imposed a tax upon the traffic passing by the Company's cables. Your Directors were advised upon these points, and to safeguard the interests of the Company, they protested against the decision of the Government, but with a view of coming to a friendly and satisfactory arrangement and understanding with the authorities in Brazil, they decided to send out a special representative to Rio Janeiro. This gentleman was instructed to negotiate with the Government for arrangements under which the interests of Brazil and of the submarine cable companies would be consolidated and protected. The time of the visit was unfortunately inopportune, as, consequent upon the civil disturbances which had only been suppressed a short time before, the Minister to whose department the business belonged was fully occupied with more pressing affairs, and did not afford our agent the opportunity of bringing forward his business. Your Directors confidently hope that at an early date, when Brazil has settled down to a state of peacefulness and prosperity, the negotiations may be resumed with advantage to all concerned. It is not your Company alone that is interested in maintaining friendly and equitable arrangements with the Brazilian authorities. Our partners—or, rather, our allies in the "pool," the Western and Brazilian Company—are, I may say, equally concerned. One company cannot be affected by the imposition of taxes on its traffic without the other participating in the charge. Your Directors have, therefore, a responsibility imposed upon them of safe-guarding interests beyond those of their own shareholders, and this is a duty they desire to perform to the satisfaction of all. Speaking of the Western and Brazilian Company, I cannot help thinking that two companies so closely allied by a joint-purse agreement having some forty years to run, each company continuing and completing the service of the other, should be more closely allied than they are. With the present separate directorates and establishments, differences of opinion and policy must from time to time arise. With a closer alliance by fusion the differences would be prevented, and many important economies effected. Personally, I feel strongly that it would be in the interests of both bodies of shareholders if their separate companies were made one. This is an important matter, and I think the sooner it is dealt with the better for all concerned. That has been my idea for many years, and it is my idea to-day, but you know the difficulties in bringing about even friendly alliances between two boards. This, however, is an important question. I know there are reasons on the part of the Western and Brazilian Company which keep them back for the moment, but, at the same time, I know that both the president and the managing director of that company have held the same opinion that I hold to-day. I hope, therefore, that the time is not far distant when this question will be dealt with in such a spirit of fairness that the shareholders in the respective companies will see that it is to their interest to support any movement made in that direction. I have now, gentlemen, in a very calm, and, I hope, very clear way, given you a considerable amount of information as to the working of this concern in the last six months. We can go on very well even if no arrangement is come to, but if we can go on better with an arrangement, why should not that arrangement be made? I beg to thank you for the attentive way in which you have listened to the remarks which I have addressed to you to-day, and I now beg to move—

"That the report of the Directors and the accounts to June 30, 1894, now submitted, be approved and adopted, and that a dividend be now declared of 3s. per share, making, with the interim dividends already paid, a total dividend of 6 per cent. for the year, and also a bonus of 1s. per share, making in the aggregate a distribution of 6½ per cent. in respect of the profits for the year ended June 30, 1894, the said dividend and bonus to be respectively free of income-tax."

The Hon. W. ST. JOHN BRODRICK, M.P., briefly seconded the resolution.

The CHAIRMAN then expressed his readiness to answer any questions which the shareholders might desire to ask; but no one rising to address the meeting, he put the motion in the usual manner, and declared it carried unanimously.

Mr. FREDERICK YOULE next proposed the re-election of Sir John Pender as a Director of the Company. The shareholders, he remarked, knew Sir John Pender so well that they would be only too glad to continue his services as Chairman of the Company.

Lord SACKVILLE A. CECIL seconded the resolution, which was carried unanimously.

The CHAIRMAN, in acknowledging his re-election, expressed his satisfaction at retaining the shareholders' confidence. They might rest assured that he should endeavour by his work to deserve its continuance. He then proposed the re-election of the Hon. W. St. John Brodrick as a Director of the Company.

Mr. J. DENISON PENDER seconded the motion, which was unanimously agreed to.

Mr. GEORGE C. SCRUTTON afterwards proposed the re-election for the ensuing year of the auditors, Messrs. Deloitte, Dever, Griffiths and Co., and Messrs. Gane, Jackson and Jefferys, at a remuneration of £50 for each firm.

Mr. EDWARD PINNOCK seconded the motion, which was unanimously adopted.

The CHAIRMAN then intimated that that terminated the business, and he expressed a hope that they would meet many times again in as auspicious and satisfactory circumstances as on the present occasion.

On the motion of Mr. SCRUTTON, seconded by Mr. JOHN NEWTON, a cordial vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN: On behalf of my colleagues and myself, I beg to thank you. While I like now and again to have a little exchange of opinions at these meetings, you probably could not have paid us a greater compliment than you have done to-day, by accepting all that we have put before you without even a remark or objection of any kind. We shall endeavour in the future to maintain this close communion, which it is so desirable should be observed between shareholders and directors, and I hope that it will be attended with the same success in the future as it has in the past.

The proceedings then terminated.

Westminster Electric Supply Corporation (Limited).

An extraordinary general meeting of the shareholders of this Corporation was held on Wednesday at the office, Eccleston-place, Belgravia, S.W., for the purpose of considering a resolution to increase the capital. Lord Suffield (Chairman) presided.

The SECRETARY (Mr. Frank Iago) read the notice calling the meeting.

The CHAIRMAN said: I have not a great deal to say on this occasion, but I may take the opportunity, first of all, of informing you that the prospects of the Corporation are very brilliant. We have passed through a great deal of difficulty, as many of you are aware, and it is now apparent that we have succeeded in our efforts. With regard to the raising of the proposed further capital I may explain that the Directors have no intention of applying any portion of it towards additional buildings. That is not at all requisite, nor do we apprehend such will be the case for a very long time, and perhaps never. But, in consequence of the very considerable increase which has taken place in our business, it is only natural that we should require extra plant, extra meters, and extensions of our mains, and of course there are also other large expenses which we must meet. Therefore, gentlemen, it is with great confidence I shall ask you directly to agree to the increase of our capital by £100,000. It is not proposed to issue the whole of this new capital nor any large part of it at once; but we must have capital, and we shall issue it according to our requirements. With the view of informing you what strides are being made in our business, I may just give you a few statistics. On December 31, 1893, the lamps on circuit numbered 131,565, of eight candle-power; now they have reached the total of 158,000. About 9,000 more are waiting to be connected, and applications are still being received at the same rate. I think you will admit that as the business grows in this enormous ratio it is necessary we should have more plant. I may say that we propose to give the existing shareholders the opportunity of taking up the new shares, supposing, of course, that you agree to the proposed increase of capital. When this is done the Board will consider the amount it is at present advisable to issue, and then communicate with the shareholders as to the terms and invite subscriptions from them. I now beg to move—

"That the capital of this Corporation be increased from £300,000 to £400,000."

Mr. E. BOULNOIS, M.P., seconded the resolution.

Mr. A. TOOTH inquired if it were proposed to cover any new ground?

The CHAIRMAN: No, we do not propose to go over any new ground. That is to say, it is not intended to go to Parliament for powers to go outside our present area.

Mr. TOOTH asked if the £100,000 would be issued in shares or debentures, and at what price.

The CHAIRMAN: It will be issued in shares, and the price will be determined upon later. We are not yet in a position to know exactly how much we shall require; but at the confirmatory meeting, which will be held in about a fortnight, we shall be able to give that information.

Mr. KEENLYSIDE inquired whether, supposing they decided upon asking for £50,000 of capital, 50,000 fully-paid shares would be issued, or whether 100,000 partly-paid shares would be offered for subscription?

The CHAIRMAN: Whatever proportion of shares is issued will be fully paid.

A SHAREHOLDER asked if that would not make a difference to their Stock Exchange quotation.

The CHAIRMAN: We have the best authority for stating that the gentlemen of the Stock Exchange do not object.

A SHAREHOLDER ventured to hope that the Board would see their way to issue the shares at par.

The CHAIRMAN: I am sure I need not say, without pledging myself or the Board in any way, that seeing the increase which has taken place in our business, you may look forward to a better dividend than you have had; but with regard to the issue of the shares at par, I want to say that we are hoping to create an absolute reserve fund. You are aware we have our depreciation fund, and certain other funds already: but we are desirous of having an absolute reserve, and I think it will be more prudent if a small premium is made with which to form the nucleus of such a reserve fund.

The resolution was then unanimously agreed to.

A vote of thanks to the Chairman terminated the proceedings.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have decided, after placing £2,000 to the reserve fund and £5,000 to the debenture redemption fund, and subject to audit, to recommend at the forthcoming meeting a dividend at the rate of £2 per cent. per annum, free of income tax, for the six months ended June 30th last, carrying forward £5,630. This dividend will be payable: 3s. per share to the ordinary shares, and 3s. per share to the preferred ordinary shares. The transfer books will be closed from November 6th to 16th inclusive.

Venezuela Telephone and Electrical Appliances Company (Limited).

The ordinary general meeting of this Company was held on Tuesday at the offices, 37, Lombard-street, under the presidency of Sir Douglas Fox.

The SECRETARY (Mr. J. Simpson) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, it becomes my duty to again address a few words to you with respect to the progress of this Company. This is our fourth annual meeting, and I am glad to feel that it is unmistakably the most satisfactory report we have been able to present to you since the initiation of the Company. You have only got to look at the second paragraph to see at once the cause of our progress being satisfactory. Our profit during the year has amounted to £7,415, as against £4,143 last year, and the sum actually earned during the year—striking out all question of balances—amounts to £2,735, showing that we are now established upon a firm, and I trust it will prove to be a regular, basis of fair income, enabling us to make a proper return not only to our debenture-holders, but also to our shareholders. I am glad to tell you that we have to-day the great advantage of the presence here of our much esteemed manager, Mr. Wallis. He has come home for a little well-earned rest, and we have taken the opportunity of asking him to attend here and say a few words. I do not propose, therefore, to trouble you by duplicating the remarks which he will make with reference to the actual working details in Venezuela; but it is only fair to him to point out that since he has taken charge of the management of the Company, there has been a substantial reduction in the operating expenses there. We find that while the business has increased from £18,444 last year to £21,284 this year, the operating expenses are actually less; and I believe that with the efforts which Mr. Wallis is still making, we may hope for, at any rate, a moderate decrease in the working expenses in the future. This year they work out at 56 per cent. of the gross receipts, against 60 per cent. last year. I should like to point out one other matter in the accounts. You will observe that our capital is represented by £70,000 in shares, £70,000 of First Mortgage Debentures, and £12,900 of Second Mortgage Debentures, making a total of £152,900; and if you turn to the other side of the account you will observe that this exactly represents at par the amount expended—that is to say, the cost of the property, the stores and materials at Caracas, and the cost of issuing the two sets of debentures. Those four items together amount to £152,000, and, therefore, the expenditure is now represented exactly by the par value—the nominal value—of our securities. I am quite sure that we are very much indebted for the good results we have obtained to the arrangements made by our friend Mr. Philipps, when he went to Venezuela. He has been there twice, but his second visit was especially fruitful of good results, and he then laid down with Mr. Wallis a plan of operations, which has been very loyally carried out by Mr. Wallis and our excellent staff under him. I think we have reason to congratulate ourselves as to the way in which the business of the Company has been carried on during the year under review. We are glad to believe that our shareholders across the water, who are very considerable in number, take an active interest in our work, and I believe they are represented here by a gentleman from Holland, whom we very heartily welcome. We believe that his presence here will encourage us all in the endeavour to do what we can to serve the interests both of the Dutch and the English shareholders, which, after all, are identical. I do not think I need take up your time any longer; but before I move the resolution which I shall propose I will ask Mr. Wallis to say a few words.

The GENERAL MANAGER (Mr. Edgar A. Wallis) said that he need not touch on the financial result of the year's working; but he thought a few local facts and features connected with their enterprise in Venezuela might be of interest to them. The number of subscribers connected at June 30, 1894, at Caracas was 1,593, being a gain during the year of 195; at La Guaira the number was 221, being an increase of 7; at Valencia the number was 278, being an improvement of 21, and at Puerto Cabello the number was 125, or an increase of 16. The total increase in the number of subscribers on June 30th last was, therefore, 239, compared with the number at June 30, 1893. During the 12 months they had carried out and paid for a considerable amount of work in order to accommodate their new subscribers. All their four offices were now fitted with multiple switch-boards, which were the most perfect yet introduced, and had been adopted in all the most important telephone systems in the world. The improvements and alterations in their La Guaira exchange had enabled him to carry out, with only comparatively little opposition, the change they had had for some time in view; namely, the enhancement of rates in that district from 14 to 18 bolivars per month, an increase which began to take effect in December, 1893. In the La Guaira district they had also carried out considerable improvements in line construction, improvements making towards directness of route and economy of distance. The repairs to their Puerto Cabello and Valencia trunk line, necessitated by the damage and destruction which occurred during the revolution, had been concluded, the cost being charged to revenue, and this line was now in excellent working order. The secretary informed him that a question was recently asked about the repairs and renovations of telephones, and it might not be out of place for him to state that each telephone as it was changed or withdrawn was put into the shop, which it afterwards left practically as good as new, the renovations being paid for entirely out of revenue. The Company had some two miles of subways in Caracas, with 21 manholes and cables laid to accommodate at present 2,250 subscribers. These subways, which were fitted with extra pipes sufficient to enable them to duplicate all existing cables should they find it necessary at some future date to do so, were laid down at considerable expense to the Company about two or three years ago, in order to introduce their wires into their central office, their iron poles in its vicinity being already overburdened. All lines now entered the office by subways. For the rest, their system of line construction was aerial, their wires being run upon iron poles and wooden cross arms. He estimated roughly that they must have about 3,000 miles of iron wire so strung in the Republic. Their offices were open night and day, and the average number of local connections effected every 24 hours in their Caracas Exchange was between 10,000 and 11,000—figures which he thought, from his knowledge of the telephone business, he might say were unique in proportion to the population. He thought there was no town where the telephone had come to be looked upon so much in the light of a household necessity as it had in Caracas. In conclusion, he would like to say that while they had not, of course, escaped the friction and difficulties incidental to a telephone business, the steady growth of the Company's business had hardly even been checked by temporary fluctuations in commercial prosperity, but had moved always steadily in one direction. He thought he might say that the steady and continual increase in demand for telephones satisfactorily proved that the very cheap and effective service rendered by the Company had not been without its reward in the cordial appreciation of the Government and the public of Venezuela. Unless any unforeseen circumstances occurred, he thought and hoped that the Company would enjoy in 1894-95 as prosperous a year as it had done in 1893-94.

The CHAIRMAN said he thought they would consider Mr. Wallis's statement very satisfactory. He then moved the adoption of the report and accounts.

Mr. J. W. PHILIPPS seconded the motion, which was carried unanimously.

Resolutions were afterwards passed declaring a dividend on the share capital at the rate of 4 per cent. per annum, and re-electing the retiring Director, Sir Douglas Fox, and the retiring auditors, Messrs. Price, Waterhouse and Co.

On the motion of the CHAIRMAN, seconded by Mr. L. FRANKEN, a vote of thanks was passed to Mr. Wallis and the staff in Venezuela for their care of the interests of the Company.

The GENERAL MANAGER having briefly acknowledged the compliment,

Mr. FRANKEN referred to the presence at the meeting of Mr. Van Es, the principal partner and manager of the Commandetaire Bank Van Es and Co., of the Hague, Holland, who had a large interest in the Company's shares and bonds, and who had attended the meeting in order to give the support of the Dutch certificate holders to the Board and the manager in Venezuela. They were very satisfied with the progress which the Company had made, and he was desired by Mr. Van Es to express the hope that the working of the Company in the future would be as efficient as it had been in the past, and to state that the Dutch proprietors would be perfectly willing to render the Company any assistance that might be required. It was the intention of Mr. Van Es to submit to the Directors a project by which the charges might be reduced to a certain extent, and the bonds be regularly redeemed, so that the debt of the Company would go down as the earnings increased.

The CHAIRMAN stated that any proposition coming from Mr. Van Es would be considered by the Directors.

Mr. FRANKEN then proposed a vote of thanks on the part of the Dutch certificate holders to the Directors and Mr. Wallis.

The motion was seconded, and carried unanimously.

The CHAIRMAN: On behalf of my colleagues and myself I beg to thank the Dutch and English shareholders, and to assure them that we shall do the best we can to promote the welfare of the Company. We are all interested in it, and in trying to serve the shareholders we are, therefore, serving ourselves as well.

The proceedings then terminated.

Eastern Extension, Australasia and China Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended June 30th last, to be submitted to the forty-second ordinary general meeting, to be held at Winchester House, E.C., on Wednesday next, at 2 p.m.:—

The gross receipts for the half-year ended June 30, 1894, including Government subsidies, have amounted to £247,681. 2s. 4d., against £257,986. 13s. 5d. for the corresponding half-year of 1893. The working expenses, including £21,295. 16s. 5d. for cost of repairs to cables and expenses of ships, absorb £80,295. 3s. 10d., against £78,229. 19s. 3d. for the corresponding period of 1893, leaving a balance of £167,385. 18s. 6d. From this is deducted £3,940. 2s. 7d. for income tax, £32,488. 13s. 9d. for interest on debentures, debenture stock, contribution to sinking fund and revaluation of currency balances, leaving £130,957. 2s. 2d. as the net profit for the half-year. Two quarterly interim dividends of $1\frac{1}{4}$ per cent. each, amounting to £62,500, have been paid for the half-year under review, leaving £68,457. 2s. 2d. to be carried forward.

The loss resulting from the third year of working, ended April 30th last, under the Australian Tariff Guarantee arrangement, amounted to £12,384, half of which was borne by the guaranteeing Governments, and the other half by the associated Cable Companies in terms of the agreement.

The laying of the Company's alternative cable between Singapore and Hongkong *viâ* Labuan was successfully completed by the Telegraph Construction and Maintenance Company, and the line opened for traffic on May 5th last. It has already been found a most valuable addition to the Company's system. A short length of cable has also been laid between Labuan and Borneo so as to give direct telegraphic communication with

Digitized by Google

Saudakan, the headquarters of the British North Borneo Company, when the land line which is in course of construction by that Company across North Borneo is completed.

Numerous cable repairs have been carried out during the half-year under review, but owing to the system being duplicated the traffic has not been affected.

Monte Video Telephone Company (Limited).

The following is the report of the Directors, to be presented to the shareholders at the annual general meeting, to be held at the offices, 96, Gresham House, Old Broad-street, E.C., on Wednesday next, the 31st inst., at noon:—

The statement of accounts for the year ended 31st July last shows a net profit of £6,902 15s. 11d. After making provision for all working expenses in Monte Video and London, depreciation of stock of materials in Monte Video, and writing off the final amount of preliminary expenses, there remains an available balance, including the amount of £775 2s. 9d. brought forward from last year, of £7,677 18s. 8d. It is with satisfaction that attention is drawn to the result of the year's working of the Company's business. The amount of subscriptions shows an increase compared with last year of £460, while the capital expenditure during the year was £875 6s. 3d., as against £1,637 4s. for the previous year. The entire property has been maintained in efficient repair at the cost of revenue. After careful consideration of the whole position of the Company, the Directors recommend the payment of a dividend of 4 per cent. on the Preference Share Capital, absorbing £5,600, which, after placing £1,000 to Reserve Account, and £500 to reserve for bad and doubtful debts, leaves the sum of £577 18s. 8d. to be carried forward to next year.

It will be observed that the position of the Company is improving, and keeping pace with the general prosperity evidenced in industrial and financial circles throughout Uruguay.

Mr. Herbert Ward retires from the Board, and being eligible offers himself for re-election; as also do the auditors, Messrs. Gérard Van de Linde and Son.

NEW COMPANIES, STATUTORY RETURNS, &c.

HALL ELECTRICAL COMPANY (LIMITED).—This Company was registered on October 16th, with a capital of £4,000, in £1 shares, to acquire as a going concern the business of electrical engineers and contractors carried on by A. Hall and Co., at Liverpool, and to carry on the business of electrical engineers and contractors in all or any of its branches. The subscribers (with one share each) are—Loftus J. Barnacle, Herbert H. Hall, Edward J. Bayley, Leslie Wilde, William Paul, Henry Jones, and John D. Malley. The first Directors are—Loftus J. Barnacle, Herbert H. Hall, and Charles E. Keizer.

LONDON WIRE NETTING COMPANY (LIMITED).—This Company was registered on October 16th, with a capital of £2,500, in £1 shares, to acquire the business of manufacturers and galvanisers of and dealers in wire netting and wire drawers carried on by Walter P. Grafton and Richard O. Williams at Millwall.

RICHARDS'S MACHINE TOOL COMPANY (LIMITED).—This Company was registered on October 16th, with a capital of £2,000, in £1 shares, to acquire the business of a machine tool engineer carried on by George Richards.

J. SUMNER (LIMITED).—This Company was registered on October 18th, with a capital of £3,000, in £10 shares, to acquire the business of an engineer, ironfounder, and machinist carried on by James Sumner at Leyland.

WIGSTON ELECTRICAL AND ENGINEERING COMPANY (LIMITED).—This Company was registered on October 23rd, with a capital of £25,000, in 2,000 Ordinary and 500 £6 per Cent. Cumulative Preferred shares of £10 each, to carry on the business of electrical and mechanical engineers, manufacturers of and dealers in electric, galvanic, magnetic, telegraphic, telephonic, and other appliances and apparatus for surgical, curative, restorative, domestic, and other purposes, and of steam, hydraulic, pneumatic, and other engines, machines, appliances, and apparatus, wholesale and retail ironmongers, electric bell manufacturers and fitters, electro-platers, cycle manufacturers, boiler makers, iron and brass founders, ornamental ironworkers, &c., and to carry on the business of an electric light supply company. The first Directors are—John T. Biggs, Orson Wright, and Thomas C. King.

ELECTRIC CONSTRUCTION COMPANY (LIMITED).—The annual return of this Company, made up to September 27th, was recently filed, when 120,000 Ordinary and 12,995 Preference shares were taken up and issued as fully paid out of a nominal capital of £400,000, divided into 150,000 Ordinary and 50,000 £7 per cent. cumulative Preference shares, all of £2 each.

ELECTRIC EXPLOITATION COMPANY (LIMITED).—The statutory return of this Company, made up to May 8th, has been recently filed. The Company has a nominal capital of £25,000 in £1 shares, of which 20,367 have been taken up. Of these 20,000 have been issued as fully paid to Max Sussmann, of Neuruppin, Prussia, or his nominees, in consideration for the transference to the Company of certain patents relating to improvements in the manufacture of secondary battery plates, portable secondary battery lamps for use in mines, and dry electrolyte for secondary batteries. Upon the remaining 367 shares the full amount has been called, resulting in the payment of £360, and leaving £7 unpaid.

ELECTROPHONE (LIMITED).—An agreement, made July 30th (and recently filed) between the vendors and the Company, states that whereas by a previous agreement the vendors decided to sell to the Company the business carried on by them under the style or firm of the "Electrophone Syndicate" for £15,000, payable by instalments in cash and the allotment of fully-paid shares, it is therefore agreed that 500 shares of £5 each shall be allotted as fully paid to Harold S. J. Booth or his nominees as part payment of such sum of £15,000.

ENGLISH ELECTRIC CARBON COMPANY (LIMITED).—The first annual return of this Company, made up to July 13th, has only just been filed. 789 shares have been taken up out of a capital of £10,000, in £10 shares, and the full amount per share has been called. The calls paid amount to £7,840, leaving £50 in arrears.

HALIFAX AND BERMUDAS CABLE COMPANY (LIMITED).—The annual return of this Company, made up to October 3rd, has been filed. The whole nominal capital of £50,000, in £5 shares, has been taken up, and all considered as fully paid.

"HARP" ARC LAMP SYNDICATE (LIMITED).—The statutory return of this Company, made up to September 24th, was recently filed, when 1,000 shares were subscribed for out of a capital of £5,000 in £1 shares. Resulting from a call of £1 per share £993 has been received, leaving £7 still to be paid.

HEMMING AND COMPANY (LIMITED).—An agreement, dated May 14, 1894, but only recently filed, made between T. L. Hemming and Company (Limited), Thomas L. Hemming, and Stephen Wright, provides for the sale to the new Company of the business of mechanical, chemical, electrical, and general engineers, electricians, &c., carried on by the vendors, for the sum of £5,600, payable £600 in cash and £5,000 by the allotment of fully-paid shares. Thomas L. Hemming agrees to stay in the service of the new Company on the same terms as he served the old. An agreement, dated June 15th (filed at the same time), with the new concern as the fourth party, adopts all the provisions of the preliminary agreement and discharges Stephen Wright from all liability under such contract.

D. HULETT AND CO. (LIMITED).—The annual return of this Company, made up to September 4th, has been filed. Out of a nominal capital of £35,000, divided into 6,900 Ordinary shares of £5 each, and 100 Founders' shares of similar value, 5,900 of the former and all the latter have been taken up, and, with the exception of 1,900 Ordinary shares, issued as fully paid. Upon these shares the full amount has been called, resulting in the total payment of £9,500.

CITY NOTES.

BIRMINGHAM CENTRAL TRAMWAY COMPANY.—A special meeting of this Company was held on Wednesday to discuss a proposition from the Directors to reduce the capital from £388,000 to £194,000, in consequence of the heavy burden of unremunerative expenditure in the early years of the Company. A fortnight ago an unsuccessful attempt was made to pass the resolution; but on Wednesday the Directors were provided with proxies representing the necessary three-fourths of the Company's capital, and, the opposition being withdrawn, the proposal was carried.

CITY AND SOUTH LONDON RAILWAY.—The traffic returns of this Company for the week ended October 21st were £932, as against £810 in the corresponding period of 1893, being an increase of £122. The total receipts for the half-year amount to £13,863, as against £12,956 for the corresponding period of 1893, an increase of £907.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment by warrants on the 1st November of interest for the half-year ending October 31st, on their Four per cent. Mortgage Debenture Stock. The transfer books will be closed from the 27th October to the 1st November, both days inclusive.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company notify that on Monday, November 19th, at noon, at the Company's offices at Winchester House, Old Broad-street, E.C., 362 Five per Cent. Mortgage Debentures will be drawn for payment on January 1, 1895. Notice will be given by advertisement of the numbers of the debentures drawn. The Company also announce the payment by warrants on November 1, 1894, of interest on their Four per Cent. Mauritius Subsidy Debentures. The transfer books will be closed from October 27th to November 1st, both days inclusive.

ELECTRICAL COMPANIES' SHARES.—At the Auction Mart on Wednesday some Electrical Power Storage Company's £5 (£3 paid) shares changed hands at 2⅜ and 2¼, and £5 founders' shares at 2¼, while £10 "A" shares (£9 paid) of the Exchange Telegraph Company realised 5¾ and 6.

INDO-EUROPEAN TELEGRAPH COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend for the half-year ended June 30th last, at the rate of 5 per cent. per annum, free of income tax, which is payable on and after November 1st. Coupons held in this country must be deposited at the bankers', Messrs. Barclay and Co., 54, Lombard-street, E.C., three clear days for verification.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended October 19th (after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited) were £3,215.

WESTERN UNION TELEGRAPH COMPANY.—The report for the fiscal year ending June 30, 1894, shows a decrease for the year in gross revenues, as compared with the year preceding, of 3,125,787dols. Expenses of operation and maintenance were reduced 1,422,235dols., leaving net profits lower by 1,703,733dols. than in 1893. The Company earned in the fiscal year a small surplus over all charges, including dividends at the old rate.
